Information filtering technique is proposed for this problem, it is aimed at different user; provide different service, to meet different needs, to learn the user's interests and behavior by collecting and analyzing user information, so as to achieve the purpose of the initiative recommendation.

Intelligent information recommendation technology is to learn the user's interests and behavior through the collection and analysis of customer information, and timely update, the realization of active recommendation information to the user. At present, the intelligent information recommendation system can be divided into two types: content based recommendation and recommendation system based on collaborative. Similar recommendation system content resources and based on the interests of the user to filter information. Recommendation system based on content has the advantages of simple, effective, the disadvantage is difficult to distinguish between resource content quality and style, but not for the user to find new resources of interest, can only be found and the user has a similar interest in information. The similarity between users in the recommendation system is based on collaborative filtering to filter information. Its advantage is to discover new information of interest to the user, but in the use of the initial system, because the system does not get the user evaluation enough, it is difficult to give a similar recommendation.

Case-based reasoning

Case based reasoning is accumulated in the case of experience as stored knowledge foundation, defines and describes the new problems, in order to capture the information to solve the new

problems. This method in the automatic correction system industry, auxiliary medical system, comprehensive evaluation and decision making has been widely applied in the field.

The premise of the CBR is to establish a case based experiences. According to the characteristics of specific areas, each experience is represented as a case. The main idea is based on experience, searched and the new question similar case, and then adjusts the draw solution to new problems for the solution according to the similar case. Visible, in the whole process of CBR, including the important part of the following: the case representation, case searching, case solution.

Case representation

The existing knowledge or experience needs to be represented as a case base, can play a role on the basis of CBR. A case can be represented as a feature vector of the form. For example, a digital camera price is determined by its brand, how many pixels, decision, optical zoom, then the brand, pixel and optical zoom can be used as features from the extracted feature space problem, is used to describe the specific characteristics of each camera to determine its price. The Olympus camera as an example, if it is known pixel is 20000000, is 3 times optical zoom, the price is 3000 Yuan, then such an experience can be expressed as a case, as shown in table 1.

Table 1 Using the feature vector representation of case

Brand	Pels	Optics	Price
Olympus	2000	3	3000

Case library

In the case of descriptive features are usually called attributes, such as the brand, pixel and optical zoom; case results or decision scheme called decision-making features, such as price. After determining the attributes, each one's previous experience can be accurately represented as a case, and thus form a case base. Table 2 shows a case base of library.

Table 2 An example of case library

Brand	Pels	Optics	Price
Olympus	2000	3	3000
Cannon	3000	5	3500
Sony	2500	3	2700

Case search

Given an unknown problem, first of all, to the given problem is expressed as the form of case, known as the case. This case is a feature vector, but because the decision value is unknown, the eigenvalue includes only the attributes and does not include the decision-making characteristics. For example, there are people who want to buy a digital camera, the requirement is Olympus, 30000000 pixels, optical zoom is the 3, want to estimate how much is the price. This problem can be expressed as shown in table 3.

Table 3 Case representation

Brand	Pels	Optics	Price
Olympus	3000	3	?

According to the principle of CBR, to solve the new problem, is found from the case base and the problem of feature values in the case of vector most similar, then use the similar case results to make a decision. Take the above example, now is to estimate the camera price, then from the case base and the case to find the most similar cases. As can be seen, where the need to measure similarity of a given. The commonly used similarity measurement method is based on the "distance" of similarity

calculation method has been widely used. "Distance" is that similarity is small. Here is the commonly used distance measure.

If the case base represented by a CB, CB ={e1, e2,... , eN} N contains a case, EI (I =1,2, -, N). Each case with n attribute Fj (1 ≤ J ≤ n) and a decision characteristics of D. In each case the case base in EI (I =1,2,... , N) can be expressed as a (n +1) dimensional feature vector, i.e., EI = (Xi1, xi2,... , Xin), Xij is corresponding to the j features of Fj (1 ≤ J ≤n). Assume that for each attribute of Fj (1 ≤ J ≤ n), a weighted WJ (WJ ∈ [0,1]) specifies the importance to measure the characteristics of the. The weighted Euclidean distance:

$$d(x,y)=\sqrt{\sum_{i=1}^{n} w_i*(x_i-y_i)*(x_i-y_i)}$$

The Information Push System Using Case-based Reasoning

The information push system using case-based reasoning is shown as figure 1.

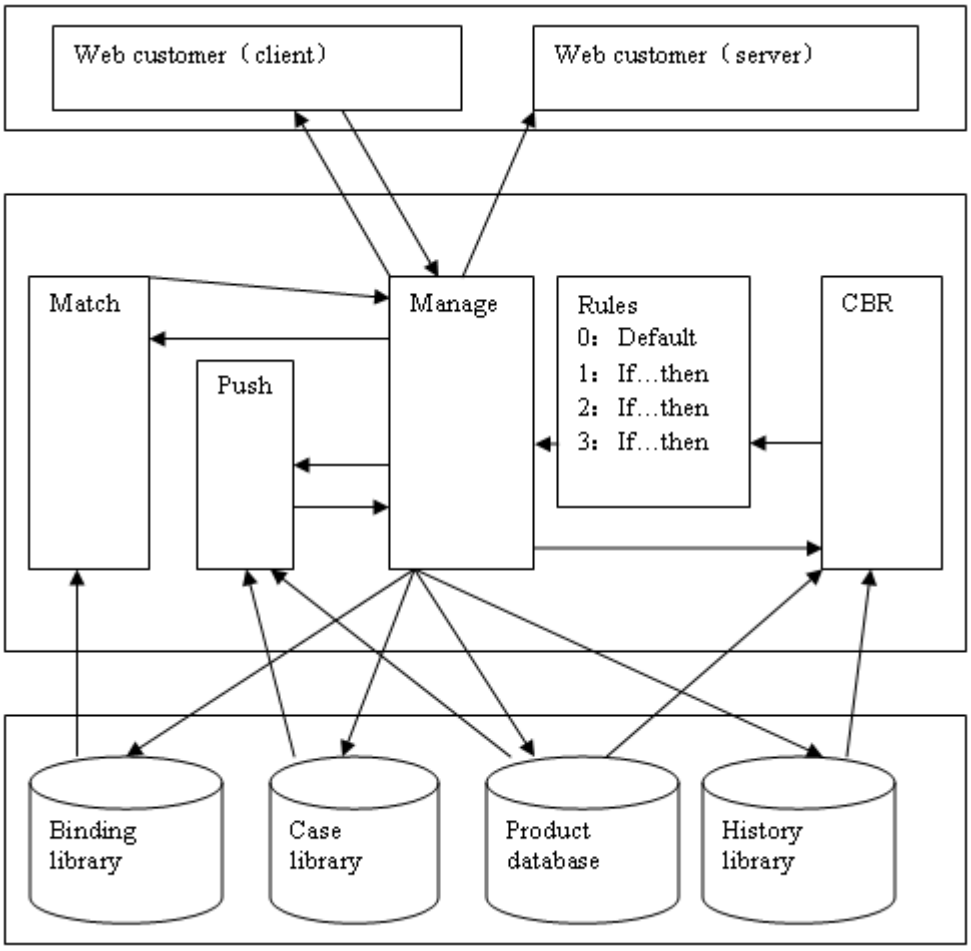

Figure 1 The information push system using case-based reasoning

First, a large number of existing, mature case previously stored in the case library. Then, according to the requirements and characteristics of the customer, according to similarity are retrieved from the case library as a case. Then, modification, composition and processing is the necessary. Finally, may be formed for different customers with new recommendations.

(1) Cases were collected and said. The typical case, collect past problem solving, is in each case by the individual characteristics, customer demand information and consumer behavior.

(2) Case retrieval. Retrieval of case base, case extraction similar to those of the problem domain and target problem, according to the customer demand information, dynamic weight adjustment characteristics and related attributes to provide recommendation results.

(3) Case matching. Calculation case similarity, the similarity measure and the results of sequencing, retrieve the matching case from the case base.

(4) Case solution. Modify and adjust the scheme for solving the best similar case as the target case solution.

(5) Cases update. The adjusted target case recommendation result as the target case solution is added to the case base, accumulate experience for the future to solve the new problems.

Summary

Information push systems play an important role in reducing information overload for people visiting online sites, but their services could be improved by using data from online social networks, electronic communication tools and others. Information push systems are used by electronic commerce sites to suggest products to their customers and to provide consumers with information to help them determine which products to buy. There are many electronic commerce applications on the Web. In this paper, we present the information push system using case-based reasoning. Then we introduce the case-based reasoning technology and analyze the case representation, case library and case search. Lastly, it gives the architecture of the information push system using case-based reasoning.

Keywords: Mesh Network, Routing Overhead, Network Topology

Abstract: Since the wireless mesh network topology dynamics and the radio channels instable, the design of wireless mesh network routing protocol become one of the key factors to determine the performance. This paper mainly studied the existing several kinds of typical three-layer mesh network routing protocol (DSDV and AODV), aimed at the defects of three-layer routing limited to the network topology changes, the paper proposed a network model based on two-layer routing. Forwarding the packet, establishing and maintaining the communication links are accomplished on the Mac layer. Simulation tests showed that two-layer routing has a big improvement on the efficiency of packet forwarding, and it effectively reduced the routing overhead and end-to-end delay simultaneously.

Introduction

Wireless mesh network (WMN) is a dynamic self-organizing, self-configuring network. WMN is mainly composed of mesh routers and mesh clients. All the nodes in a mesh network automatically establish a dynamic network and maintain network connectivity[1]. Wireless mesh network become one of the hot spots in current research due to its wide range of applications and network flexibility, low cost, easy to expand and so on. WMN routing algorithm must be based on the characteristics of multi-hop wireless networks to satisfy requirements.

Routing protocol analysis

DSDV protocol is a distance vector protocol. The design idea is to maintain a monotonically increasing sequence number of the destination node for each route. In the case of don't need to collaborate with adjacent nodes, contrast the serial number of nodes to prevent appearing routing loops[2] . DSDV protocol stipulates that the destination node serial number stored in the routing table entry of each network node. By joining in packet destination node domain, the destination node distance information exchanged mutually in the adjacent nodes with each routing updates. In this way, each node using the distance vector received from the neighbor node to update their routing table, to make sure the current routing is latest and best.

But in the condition of network topology changes frequently and high-speed mobile nodes, the convergence performance of DSDV protocol will worsen sharply. Whether the node needs to send data or not, it requires broadcasting updating information to the adjacent nodes periodically. So, the more nodes join in the network, the larger the network traffic density, and the capacity, cost of the routing table and bandwidth increasing will increase network load[3] . Limited network scale is the main drawback of DSDV protocol.

AODV is a typical on-demand routing protocol. It is proposed based on the DS-DV algorithm and combined the on-demand routing mechanism of DSR algorithm.

Design of routing scheme

In fact, the performance of the variety three-layer routing protocols are different in the specific different networks, the complexity of the network topology has a lot to the conditionality of marketable by the performance of the agreement, The complexity of the network topology has a lot conditionality to the performance of the protocol.

Two-layer routing protocol is the proactive routing protocols based on node topology. It can be implemented by either centralized or distributed strategies. The differences between two-layer routing protocols and traditional protocols are: the two-layer protocols address by the MAC address and forward through two layers[4] . The upper layer protocol stack do not need for additional splitting and encapsulation. Neighbors, topology built and maintained in MAC layer, requires no additional sending notice, updating routing messages to create and maintain the routing. This can reduce the system overhead brought by the routing protocol, save bandwidth, and reduce the delay[5] . Especially suitable for the multi-hop networks with high real-time demand of data transmission, large number of nodes and complicated network structure.

Here discussed the mesh node routing, assume a neighbor relationship table:

	1	2	3	4	5
1	0	1	0	0	0
2	1	0	1	1	1
3	0	1	0	1	1
4	0	1	1	0	1
5	0	0	1	1	0

Node 1 as an example to describe the process of routing path discovery:

(1) The neighbor of node 1 (level 1) is node 2, record the arrival path:

1－＞2

(2) The neighbor of node 2 (level 2) is node 3, 4, record the arrival path:

1－＞2－＞3

1－＞2－＞4

(3) The neighbor of node 3 (level 3) is node 2, 4, 5, the arrived is no longer record:

1－＞2－＞3－＞5

Now found that all nodes have finished traversal, so the final routing information of node 1 is as follows:

1－＞2

1－＞2－＞3

1－＞2－＞4

1－＞2－＞3－＞5

Routing addressing and data forwarding

Packet routing mainly involves the following several modules: Mac Layer, Mesh Route and IPFM. The protocol stack is shown in figure 1:

(1)MAC Layer mainly responsible for the allocation of resources, time slot and conflict avoiding and maintain network topology table topo_table and the neighbor table neighbour_table;

(2) Mesh Route is mainly responsible for network topology table obtained from the MAC Layer, and calculates the two-layer routing and selects the path.

(3) IPFM forwarding management for IP, The main function is the forwarding of host routing and the maintenance of host routing table host_table.

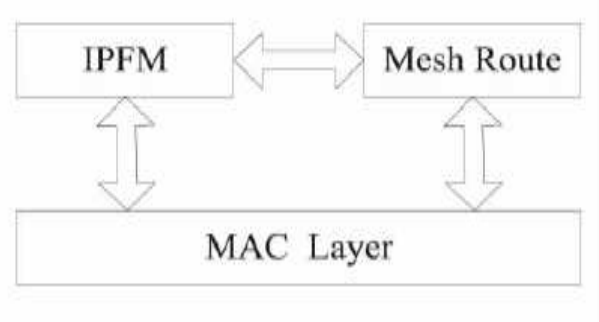

Fig.1 Protocol stack model

In order to reduce the processing delay, we can use the mixed two-layer and three-layer mode to forward. Increase the target node identification in forwarding data. If the destination node is not itself after the receiver receives the data, then check the next-hop node of the target node by Mesh Route, forwarding on the second layer and don't need to check routing; If the destination node is itself, then send to IPFM routing module to discover route and forward.

Test result

In this paper, we use NS2 software to simulate under the Linux operating system. 1000m×1000m simulation area uniformly distributed 50 wireless Mesh nodes. The distance between each test nodes is larger than 100 m, and the maximum rate of mobile node is 25 m/s. Under the same simulation scenario, by changing the movement speed of test node, we compare the routing overhead and the average delay of typical three-layer AODV and two-layer routing algorithm, and simulated the network throughput under different network topology.

Routing overhead refers to the amount of the average control group used to transmit a group successfully. The selection of routing algorithm greatly influences the routing overhead.

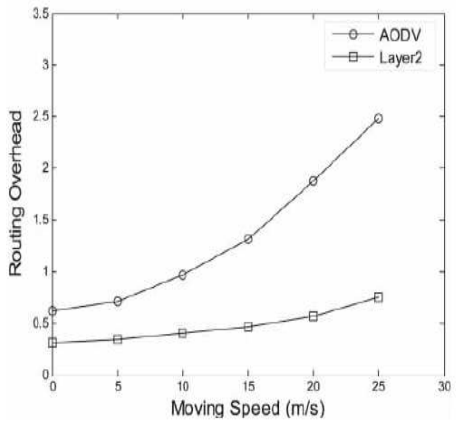

Fig. 2 Routing overhead

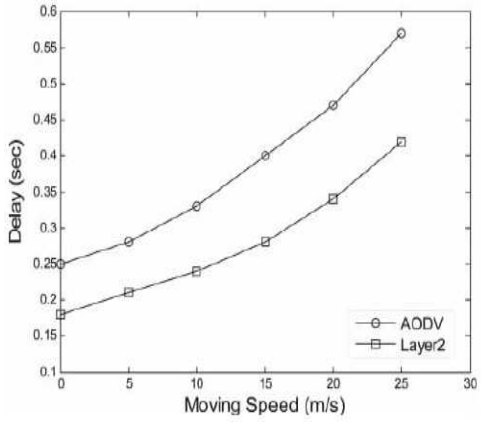

Fig.3 Average end-to-end delay

As shown in figure 2, two-layer routing has obvious more advantages in routing overhead than AODV routing. The increase of node speed leads to greater risk of link disconnected, at this moment need more system overhead to repair links. Since the stability of the node topology built and maintained on MAC layer in the two-layer routing scheme, requires no additional sending notice, updating routing messages to create and maintain the routing, improving the efficiency of the routing and packet delivery success rate, also lower the number of the fixed link simultaneously, thus largely reduces the network routing overhead.

The end-to-end delay is the time difference value of data packets from the source node to destination node. It can effectively measure the time efficiency of the routing algorithm. The delay jitter is particularly important for voice video stream demanding high real-time requirements.

As shown from the figure 3, with the change of node location and increase of speed, the possibility of the routing path breakage increases and needs more extra time for topology stability and routing reconstruction. So the end-to-end delay also increases accordingly. While the two-layer routing forward the packet on the Mac layer. On the one hand, it reduced the encapsulation and

splitting of protocol, and forward faster. On the other hand, maintain the link stability on Mac layer is more quickly and efficiently than on the IP layer, so obviously reduces the end-to-end delay.

Conclusions

This paper studied and analyzed the characteristics and defects of the existing typical Ad Hoc network/Mesh structure routing protocols, proposed the scheme design based on the two-layer routing to forward the packet and establish and maintain communication links on the Mac layer. Simulation tests show that packet forwarding on the second layer improving the efficiency of the system delay and forwarding efficiency, especially suitable for complicated multi-hop networks.

Research of Ad Hoc Network Routing Based on NS2 by Performance Comparison

Xiaolong Tan[1], Jia Zhou[1], Wenbin Wang[1,a]

[1] Yalong River Hydropower Development Company LTD, Chengdu, 610051, China

[a] email: wangwenbin@ylhdc.com.cn

Keywords: Ad hoc Network, Self-Organization Network, Packet Delivery Ratio

Abstract: In recent years，the ad hoc network has been paid extensive attention due to its characteristics of non-center and self-organization．Firstly this paper introduces three typical routing protocols AODV，DSDV，DSR，and the principles of them; then，adopts the NS2 simulation platform to simulate the performance of end-to-end delay，routing overhead and packet delivery ratio by changing the number of nodes and the paused time of nodes．Finally，by comparing the simulating results, the comparison conclusion is provided．

Introduction

Ad hoc network is a distributed wireless multi-hop networks without central control nodes. It does not need the support of fixed infrastructure. Each user can network automatically and forward data through other nodes.

According to the characteristics of the ad hoc network, a variety of ad hoc protocols has been developed, such as AODV, DSDV, DSR, TORA and so on[1] . This paper analyzed the performance of the end-to-end delay, normalized routing overhead and packet delivery ratio for AODV, DSDV, DSR, and made a comparative analysis.

Ad hoc network routing protocols

Existing ad hoc routing protocols are mainly including table driven routing protocols and on-demand routing protocols. DSDV belongs to table driven protocols, and DSR, AODV belongs to on-demand protocols[2] .

The exchange of message occurred between adjacent mobile nodes in DSDV, if the routing information of destination nodes which send a packet is unknown, the groups will be buffered, and the routing query message RREQ sent at the same time until receiving the route reply message RREP.

The DSR is mainly divided into two parts, route discovery and route maintenance. When the source node send data to the destination node, first check the route buffer if there is a route to the destination node[3] . If there is, send data using this routing, otherwise starting routing discovery process. Routing maintenance completed by routing error group and acknowledge group.

AODV is essentially the combination of the DSR and DSDV, it has the routing discovery and routing maintenance function of DSR, at the same time adopt hop-by-hop method of DSDV[4] .

The performance indicators and the selection of simulation parameters

(1) The average end-to-end delay: it represent the average time of source node sends the packet to the destination node.

(2) Normalized routing overhead: the total number of packets used for route discovery and route maintenance divided by the number of received packets, during the process of packets from the source node successfully transmitted to destination node.

(3) Packet delivery ratio: successfully received packet number of destination node in proportion to the number of packets sent by source node[5] .

The performance comparison under different number of nodes

Simulation scenario: 600m×400m area respectively distribute 25, 50, 75, 100, 125, 150 mobile nodes, there are 10 pairs of communication links, sending TCP business.

(1) End-to-end delay

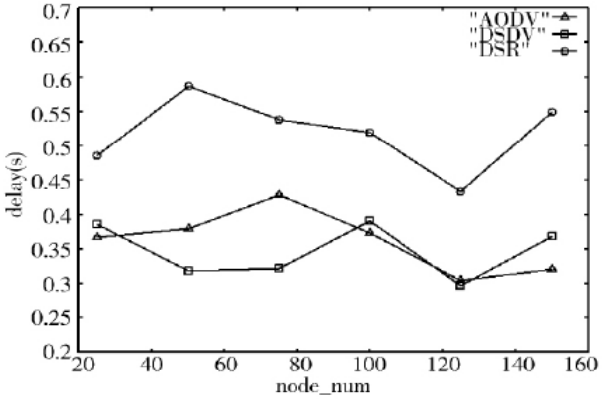

Fig. 1 The average delay under different number of nodes

Figure 1 shows the average end-to-end delay of communication nodes under different number of nodes. It can be seen that the DSR's average delay is generally greater than AODV and DSDV, AODV and DSDV delay value is relatively closely. Because DSR search the best routing in the routing cache, the large cache and routing errors will cause the large end-to-end delay.

(2)Normalized routing overhead

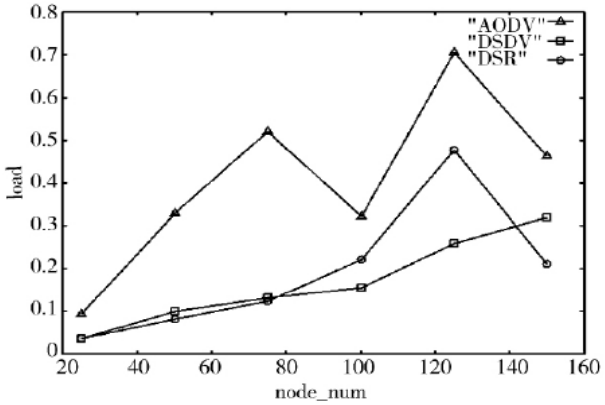

Fig.2 The normalized routing overhead under different number of nodes

Figure 2 shows that with the number of nodes increase, routing overhead of the protocol is increase overall. When the node number is large, the routing overhead of DSR is lower than AODV. Because the DSR protocol uses the routing cache technology, intermediate nodes do not need to maintain routing tables like AODV protocol. DSDV routing overhead is least, because each node in the network have kept a routing table recording the destination node and the hops to the destination node, the routing hops of each node is already determined in the process of sending messages.

(3) Packet delivery ratio

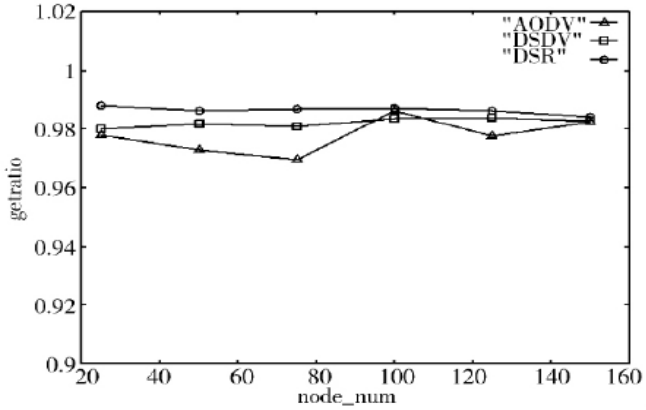

Fig.3 The packet delivery ratio under different number of nodes

Figure 3 is the comparison of the data packet delivery ratio for variety protocols. It shows that the changes of packet delivery rate for DSDV and DSR protocol is closely.

The performance comparison under different paused time

(1) end-to-end delay

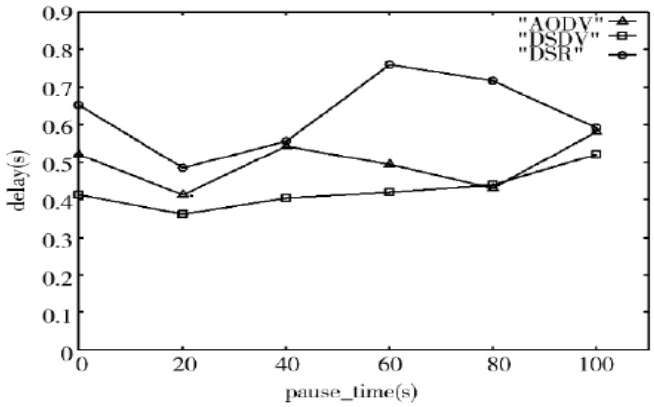

Fig. 4 The average delay of nodes for different paused time

Figure 4 reflects the average end-to-end delay under different paused time. The average delay of DSR and AODV value higher than DSDV, and DSDV delay value increased with the extension of paused time. In the DSDV protocol, each node maintains the routing information table of other nodes, it can be sent immediately via lookup table, without time consuming of looking for routing on demand.

(2)Normalized routing overhead

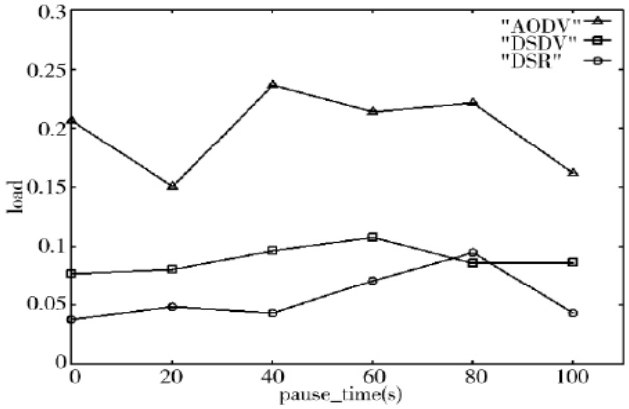

Fig. 5 The normalized routing overhead for different paused time

Figure 5 shows the relationship of routing protocol overhead among three kinds of routing protocols. It can be seen that the overhead of DSR is least. For the DSR, when the paused time of nodes increases, the dynamic topology of network abated, so routing overhead reduced. the overhead of DSDV has less relationship with node mobility, so the influence caused by node paused time is not obvious. AODV is an on-demand routing protocol, the large routing request increased the routing overhead.

(3) Packet delivery ratio

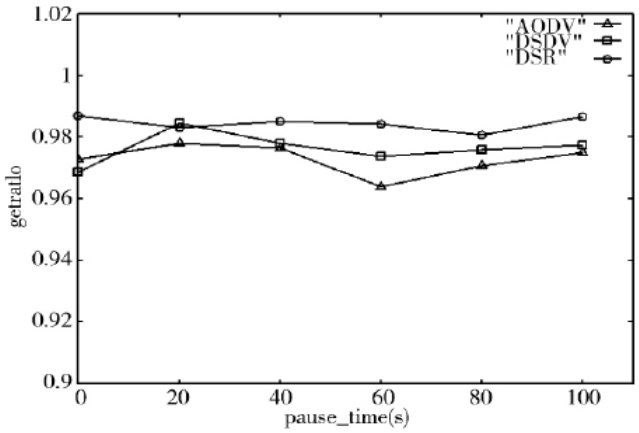

Fig.6 The packet delivery ratio for different paused time

Figure 6 is the comparison of packet delivery ratio for various routing protocols. It can be seen from the diagram that the packet delivery rate dynamic changed with the change of paused time, and the packet delivery ratio of DSR and DSDV is better than AODV. DSR is the on-demand protocol. It can be rapidly find a route to the destination from the routing buffer. But DSDV is the table driven protocol, each node must form routing tables include the routes to all nodes of the entire network, so the network resources consumed too much and packet delivery ratio is not high.

Conclusion

This paper introduced the NS2 simulation and performance comparison of ad hoc network routing protocols DSDV, AODV and DSR. The DSR protocol has maintained high packet delivery ratio and low routing overhead, but the average end-to-end delay is large; The influence of DSDV performance caused by the number of nodes and the change of paused time is relatively stable; The delay of AODV is relatively small and routing overhead is large. The overhead increases with the increase of network density. Visible, the different routing protocol has its own advantages and disadvantages and applications, separately using a routing protocol may not be able to meet the various requirements, at the same time. Therefore, hybrid routing protocols can be considered.

In addition, in the process of construct actual wireless network need to consider the particularity, the network scale and extensibility of ad hoc network. Select the appropriate network topology contributes to designing appropriate protocols for specific network structure and maximize the performance of the entire network.

Research of the Computer-aided-translation Software

Su Han[1,a] and Xindai Zhang[2,b]

[1,2] Department of Basic Courses, Shandong University of Science and Technology, Tai'an, 271000, China

[a]email:hs56923@163.com, [b]email:1561750710@qq.com

Keywords: Computer-aided translation; Research; Software

Abstract: In recent years, with the rapid development of computers, computer-aided-translation software has been used more often, which can improve the efficiency and quality of translation. This paper analyzes the characteristics of the four commonly used computer-aided- translation software at home and abroad--SDL Trados, Déjà Vu, Wordfast and Yaxin in satisfying different users' needs, points out their characteristics and provides reference for those who are interested in computer-aided- translation technology.

Introduction

Computer-aided translation has originated from machine translation, but there is a sharp difference between the two. Machine translation attempts to replace translators by means of completely automated translation process, but computer-aided translation is to utilize computer technology to improve translation efficiency and quality, in which a translator still plays the decisive role. In a broad scene, computer-aided-translation tools refer to all the computer tools which can assist the translators with their translation. They include word-processing software, grammar checkers, e-mails and the Internet [1]. In a narrow sense, they refer to the special computer-aided-translation software designed for improving the translation efficiency and optimizing the translation process[2],which includes translation memory system, terminology management tools, the alignment tools and project management tools.

Brief Introduction to Computer-aided-translation Software

It was in the 1970's that the first translation memory tools came into being. But it was not until the middle of the 1990's that they began to develop commercially. Afterwards a lot of translation-aided-translation software has poured into the markets like mushrooms and been recognized and utilized by more and more translators. Now in the international arena, there are such famous CAT(computer-aided-translation) software as Déjà Vu, Wordfast, Idiom, Catalyst etc besides the leading brand-SDL Trados. In 1998 the foreign CAT software came into China's translation market. In 1999, the CAT software of the China's Yaxin Company came into the market. Afterwards Chuanshen, Yongli, Saidi, Xueren and other companies have researched, developed and put out their own CAT software one after another.

According to the network investigation of the application status quo of CAT in the Chinese translation industry made by Xiaochen Hou and Yuzuo Yan of the CAT Department of Beijing University in 2008, about 66% translators used CAT tools in their work, 85.8% of whom used Trados, 29, 68% of whom used Yaxin CAT 3.0+CAM (Computer-aided Match), 26.45% used Déjà Vu X and 20.65% used Wordfast. According to the investigation result, now SDL Trados, Déjà Vu, Wordfast and Yaxin are the four commonly used CAT software both at home and abroad[3].

Research Base

Researchers at home and abroad have made many valuable research into the CAT technology. For example, Quah [4] and Duoxiu Qian [5]have introduced many aspects of knowledge which CAT technology involves. Lisong Lv and Lei Mu [6]have put forward paying great attention to the training of translation talents from the angle of combining translation teaching with the translation market. Jun Wen and Yan Ren [7] have made more comprehensive commentaries on the history and the present situation of China's CAT research and predicted its future direction of development. But the researches have seldom probed into the evaluation of CAT software and have not formed a uniform assessing standard.

As we know, CAT technology is mainly concerned about how to use computer software to realize automatic translation process, improve the efficiency of artificial translation process, guarantee the quality of manual translation and efficiently control the whole translation process. Therefore translation memory system, terminology management tools, the alignment tools and quality assurance tools are the four big modules to guarantee that CAT tools realize their main functions. On the basis of users' concept of quality, combined with our using experience of SDL Trados Studio 2009, Déjà Vu X 7.5, Wordfast series and Yaxin CAT 3.5, we'll make a comparative study of the four common software's functionality and usability. The functional index mainly probes into their differences and similarities in the four main functional modules of translation memory system, terminology management system, the alignment tools and project management tools. The usability index is mainly concerned about the effective working area of software interface and whether it has a Chinese interface. Then we'll further point out their characteristics so as to provide some reference for those who are interested in CAT technology when choosing CAT software.

Result of Comparative Research

A. Functionality

(a) The comparison of translation memory systems

The above four commonly used CAT software at home and abroad are all functional rich, including such functional modules as translation memory system, terminology management system, the alignment tools, automatic translation, file filter, electronic dictionary and the spelling and grammar checker. Because all the CAT software is established on the basis of translation memory technology, the translation memory bank is the core of CAT software. The translation memory systems of the above four tools can all establish and guide-in one or more translation memory banks, and the operating procedures are almost the same.

When a translation memory bank is established, the language and other parameters should be determined in advance. The file extension of the translation memory bank, which SDL Trados Studio 2009 generates when the translation memory bank is established, is .sdltm. When the related translation memory files are guided into the established translation memory bank, it can be compatible with the files which comply with the standard of translation memory exchange. It can also guide in the bilingual files of SDL XILFF and the translation memory files which the former editions of TRADOStag and SDL Edit software have customized according to their own standards. Other forms of translation memory files need to be changed into TMX(Translation Memory eXchange) form, then can be guided into translation memory bank. The file extension of the translation memory bank established by Déjà Vu X 7.5 is .dvmdb, which is the typical mdb database formatted file and has the strong compatibility. Its memory bank can directly guide in the delimited text file, the Access 9X/2000/XP and Excel 9X/2000/XP files of Microsoft Office Software, the translation memory document of Trados translators' station and TMX format

documents. In addition, it can also use the file format conversion function owned by the 7.5 edition to change the translation memory files of the Déjà Vu 2.X/3.X into the new edition of the translation memory document for the use of translators. What the translation memory bank of WFC 6.0 uses is Wordfast's own translation memory format, which is compatible with TMX format translation memory bank document. The translation memory bank documents established by WFP 2.1.8 are test files, into which Wordfast itself free format can be guided, and at the same time are compatible with TMX format. Besides guiding-in the early edition of Wordfast translation memory files, WFA 1.5.0 is compatible with the translation memory file format of Trados, Idiom and SDLX tools. The generated file extension of Yaxin CAT 3.5 is. mem. It is compatible with the forms of Excel 8.0 text file, TMX file and Yaxin 2.5 translation memory files. As far as the service conditions of translation memory banks are concerned, WFC 6.0's compatibility is the worst and Déjà Vu X 7.5's compatibility is the best.

(b) The comparison of alignment tools

Only when the content of its translation memory bank constantly increases can CAT tools play a more and more important role. There are two methods for translation memory banks to enlarge the contents: 1. To deposit the translated text and the source text into the translation memory bank. 2. To guide the collected source texts of all fields and their corresponding translated texts into the translation memory bank. The successful guiding-in of these documents can't do without another important module-alignment tools. The users of SDL Trados Studio 2009 need use WinAlign Module of SDL Trados 2007 to align the original with the translation in the unit of a sentence before guiding them into the translation memory bank so as to make them into the translation unit of translation memory bank.

Déjà Vu X 7.5 itself has the alignment tools which can be used directly. WFC 6.0 has no alignment tools itself. If needed, Plus Tool free of charge must be installed, which can be used for the alignment process as a plug-in of Word, but it can only work in Word 2003 and the former editions. WFP 2.1.8 has no alignment tools either, its later edition has Wordfast Aligner but isn't integrated in WFP interface and need start alone. WFA 1.5.0 uses its own Wordfast AutoAligner still in the experimental stage for alignment. The user can upload the document to be aligned free of charge, the module can align it through intelligent judgment, then send the alignment result to the user's registered mail in the three formats of text file, Excel file and TMX form. Yaxin CAT 3.5 doesn't have the alignment tools and need be installed the independent CAM module for the alignment. The operating procedures of the four above tools are almost the same all through certain separation signs to segregate text and then align it, but all of them can't deal with the situations of one-to-many and many-to-one, so the aligned text need the manual correction.

(c) The comparison of terminology management tools

Terminology management tools are used for establishing, maintaining and managing the Term Bank. The translators can store the technical terms of specific industry into the Term Bank, extract and use them in later translation.

Yaxin CAT 3.5 has 74 specialized term banks but the term banks of the other three software require the translators to add or guide the existing nomenclature made by other people into the local term bank to increase its capacity.

MultiTerm, the terminology management tools of SDL Trados Studio 2009, is a separate module, providing a converter which can convert the nomenclature in the Excel format into TBX format and the term extraction tool. It has powerful functions.

The terminology management tools of Déjà Vu X 7.5 have special features, including Terminology and lexicon. Lexicon is closely linked with the ongoing translation project and more targeted. Therefore in the process of actual translation, Déjà Vu would first search for lexicon, then search for terminology and at last search for translation memory bank. This hierarchical searching, querying and managing system is more suitable for the actual situation of translation.

WFC and WFP all carry out terminology management through the menu of Terminology, while WFA adds terminology through "Glossary Panel".

Yaxin CAT 3.5 manages the term bank through the Tab of Database Maintenance. "Database Maintenance" can not only add a single term, but also add term entries in batches.

(d) The comparison of project management tools

Translation project management refers to the process of guiding-in, analysis, pre-translation, grammar and spelling checking and export. The standardized project management process is very important for improving translation efficiency.

After creating a project, SDL Trados Studio 2009 guides-in the file to be translated, makes use of the tab of "Analyzing File" to analyze and determine translation's amount of work and repetition rate and utilizes the existing translation memory bank and term bank to pre-translate and carry out the translating word count of the project. After finishing the translation project, "the functions of spelling check" and "verification" can be used to check the translation in spelling, the consistence of grammar and terms. Then we can export well-translated file.

When using Déjà Vu X 7.5 to finish a new translation task, the translator must build a translation project folder, guide the file to be translated into CAT tools and keep all the results of the translation project management activity in the project folder. Déjà Vu X 7.5's functions of word count, pre-translation and quality check are the same as those of SDL Trados Studio 2009, but its "Analysis" menu can not only count the repetition rate but also show the situation of fuzzy matching so as to help the translator to better predict the translation process.

WFP 2.1.8 must be installed Project Manager to realize the complete project management function. The related icons of the respective software must be clicked to set parameters for the quality assurance function of WFC 6.0 and WFA 1.5.0; for WFC6.0, the tab of "Setup" need be clicked then, afterwards the tab of "QA" need be selected to set quality assurance parameter; for WFA 1.5.0, "Pandora's box" need be opened, then the fourth functional parameters setting variables "Configure Document's translation with proofreading" is clicked to pop-up proofreading function dialog box to set for its use. There is no pre-translation function in WFC 6.0's functions, while WFA 1.5.0 can carry out pre-translation after guiding-in translation memory files and nomenclature.

With the help of grammar and spelling checkers owned by Word Software, Yaxin CAT 3.5 doesn't have the functions of word count and pre-translation. The project management of Yaxin belongs to an independent function module, which the project manager completes utilizing Yaxin's relative software.

B. Usability

(a) The effective working area of interface

Interface is the important parameter to evaluate the usability of CAT software. Most of the office software is Microsoft Office, especially the Word file format, so all kinds of CAT software is compatible with the format.

When SDL Trados 2007 is used to translate, the software is cooperatively used with Word. It belongs to semi-independent interface. When a translator uses the CAT software, the main

translation work is finished in the Word interface, while the translator's working station operates as a background program. But the translator's working station and Word operate at the same time, which evidently brings inconvenience to the translation, because translator's working station probably occupies one-fourth of the whole screen. SDL Trados Studio 2009 integrates workbench with Word in the same interface, which overcomes the inconvenience which the interface of 2007 edition brings to translation activity.

WFC's interface has no independent interface. Its software agent is a Word plug-in component, and operates completely on Word's macroefficiency. All the translator's work is finished in Word. Both WFP and WFA take an independent interface. WFP requires users to translate in the independent interface of the software, while WFA requires the translator to use browser to do translation work in webpage.

The different versions of Déjà Vu software have not depended on Word software. All of its translation activities are finished in its own independent interface. In the working interface of Déjà Vu X 7.5, all the functions are centered on the inside. It is as clear as a form, the leftmost side is the original, the middle is the translation and the rightmost side is the other auxiliary translation functions.

Yaxin CAT 3.5 can work cooperatively with Word. The layout of its interface has four parts: the original zone, the translation zone, reference example zone and Word Window. In such an interface, it operates more intuitively and conveniently to synchronously finish translation in the translation zone and Word interface.

(b) The Chinese interface

Besides the effective working area, it is an important reflection of the CAT software's usability whether the interface can be set to Chinese for the Chinese users, because the Chinese interface can make the operation of CAT software and the system setting easier. Both SDL Trados Studio 2009 and Yaxin CAT 3.5 have Chinese interfaces, Déjà Vu X 7.5 has no Chinese interface and must be installed the Chinese language pack to show the Chinese interface, while all the versions of Wordfast don't have a Chinese interface.

C. Characteristics

The above four CAT tools have their own characteristics.

SDL Trados Studio 2009 is the only CAT software of directly processing PDF document without the file format conversion. In addition, it is sold together with a local tool software-SDL Passolo 2009 and can translate the executable file, resource file and the file in XML format in the visualization window of "WYSLWYG "(what you see is what you set) ,saving the complicated process of taking the words of source language out, guiding them into the CAT tools to translate and then guiding the translation into the original document. That is to say, SDL Passolo can let the translators directly carry out the translation in the document, then directly compile the document which has the same function as the original document.

When adding the translation memory and terms of Déjà Vu X 7.5, we can use the automatic transmission mode to add, which is convenient and fast and its translation memory bank and term bank are stored in the form of data file and can be transplanted, which helps to guarantee the uniformity of terms and the translation style through exchange when the team works. At the same time it is compatible with the translation memory bank and term bank of SDL Trados.

In Wordfast series software, it is its online version that has the most features, i.e. WFA, which the translators can register and use free of charge, not limited by any version or time. But only 500 translation units can be added to its translation memory bank once a time, which is not very suitable

for the operation of big translation project. The registered user of WFA can not only use his own local translation memory bank, but also anonymously use the very large translation memories free of change.

When a translator uses CAT 3.5 to do translation work, the screen can take the word and insert the explanation given by the term bank and lexicon into the place which needs to be edited, which is unique in the whole field of CAT software. The words in its English-Chinese, Chinese-English dictionary amount to more than 7 million. When we meet the sentence to be translated which is beyond the matching values of the system settings, Yaxin's computer-aided software would give the reference sentence for us.

V. Summary

From what has been said above, we can understand the functionality, usability and characteristics of the 4 commonly used CAT tools. We hope that they will be helpful to the translators in choosing the software so as to efficiently finish the translation work..

Keywords: Alfresco database; Data management; Lucene search engine

Abstract. The Alfresco development tool, which includes Apache Tomcat, MySQL and WebService, is an open platform for building a functional database system in a Java website. In order to improve the enterprises' management efficiency in specialized industrial townships, a micro-information system based on Alfresco development tool has been proposed. In the construction of the micro-information system, Alfresco database exhibits great superiority in network database architecture, data query with Lucene search engine, data management and data security. In this paper, the general design ideas, functions, key technologies and realization methods of the Alfresco database are introduced.

Introduction

Since the opening-up policy has been carried out in China, Guangdong province has developed quickly in the last 30 years and acts as the forerunner of china's economic reform. In the past ten years, there are more and more specialized industrial townships with characteristics of Guangdong's economical model founded. Since specialized industrial townships develop persistently and rapidly, it is prominent and essential to strengthen the ways to promote the brands and exchanges for enterprises in specialized industrial townships. However, for enterprises in specialized townships recently, no such efficient platform has achieved these functions. In order to achieve more effective ways for these enterprises to promote their information communication, it is required to construct a micro-information system platform for these enterprises. Data storage, data management and data mining are the key technologies to the micro-information system.

Alfresco is an open source development tool for Enterprise Content Management (ECM). It adapts to MVC pattern which divides a given software application into three interconnected parts. Alfresco development tool manages all the contents, such as documents, images, records, web pages, or any other unstructured or semi-structured file. Alfresco is functional in controls and services, such as version control, meta-data management, workflow, search, life-cycle management, associations to other content, tagging, commenting and so on. For the mountain of information which is accumulated in enterprises, you can find the content you want with these services easily and can ensure its accuracy. Alfresco that runs as a web application within an application server is composed of some open source components, and exposes repository through many different protocols and APIs.

In this paper, Alfresco database of the micro-information system is introduced in terms of the basic concept of Alfresco development tool, operation of Alfresco SDK, for the purposes of improving the enterprises' management efficiency. Furthermore, the conclusion will be obtained in the end of paper.

Development of Alfresco database

Alfresco is an open source Enterprise Content Management system. It's primarily implemented in Java, suited to a number of environments including J2EE. It is not tied to any particular web browser, operating system, application server or database. The binary streams of content are stored in the

Alfresco database and the associated full-text indexes are maintained by the Lucene indexes. The actual binary streams of the content are stored in files managed in the Alfresco database, although these files are for internal use only and do not reflect what you might see through the shared drive interfaces. The Alfresco database also holds the associations among content items, classifications, and the folder/file structure that is maintained in the database and not reflected in the internal file storage structure. The Alfresco database implements and exposes these services through an Alfresco API and the Java API. The storage engine of the Alfresco database stores and retrieves content, metadata, and relationships, and operates on the nodes and contents.

1. Alfresco SDK configuration

Alfresco provides a developer oriented download bundle, known as the Alfresco SDK (Software Development Kit) to complement the Alfresco release bundle. The Alfresco SDK provides support for developers who wish to extend or customize the Alfresco database. In order to use Alfresco SDK, we should do the following things. First of all, ensure the development tools such as JDK and Eclipse IDE are installed. Then download the Alfresco SDK and import the whole project to the Eclipse IDE.

2. Operating Alfresco SDK

(1) Identity Authentication: Before operation being done on the Alfresco development tool, the identity authentication is required . The project AuthenticationUtils in Alfresco SDK provides a utility class which manages the privileges. For this purpose, function StartSession and EndSession ensure the security of the system. The source code likes as follows.

```
1 AuthenticationUtils.startSession("admin", "password");
2 AuthenticationUtils.endSession();
```

Here the function StartSession() gets the authentication and verify its authority. In this way, the safety of system can be guaranteed. The function EndSession() ensure the security when logging out the system.

(2) Node creation: The project CML, which is short for Content Manipulation Language, provides a set of statements to update Alfresco database. And we can use the following code, in which the function CMLCreate() and CMLWriteContent() realize the main function, to create a node in the database.

```
1 cml.setCreate(new CMLCreate[]{create});
2 cml.setWriteContent(new CMLWriteContent[]{writeContent});
3 UpdateResult[] result = WebServiceFactory.getRepositoryService().update(cml);
```

In this code, the function CMLCreate() initializes the class and the function setWriteContent() sets up the creation information. And then the function UpdateResult() is used to perform the create operation. These three statements insert data into the database while the data are stored in Alfresco database as nodes.

(3) Content creation: In order to insert the content to the node, the following classes are needed. The Reference class is used to describe the address of the node. And the format of content including the type and encoding is determined by the ContentFormat class. The byte stream of the content is described in the Content class. The content can be created into the database using the following code.

```
1 Contentcontent=WebServiceFactory.getContentService(). write(referenceForContent,
2 Constants.PROP_CONTENT,"This is the content for the new node".getBytes(), format);
```

Here the content, which can be pictures, a list of string and so on, to the node we defined is inserted. And These contents of the node would be stored in the folder of the Alfresco server instead of the database. Therefore the efficiency of the search in database will be improved greatly.

(4) Node deletion and updating: The CMLDelete class achieves the delete operation to the nodes in the database, the code of deletion and update operations likes as following:

```
1 cmlRemove.setDelete(new CMLDelete[]{delete});
2 WebServiceFactory.getRepositoryService().update(cmlRemove);
```

Here a node defined in the database will be deleted, after the position of the node is defined in the line 1 and the delete operation is executed in the line 2.The CMLUpdate class is used to achieve the update operation to the nodes in the database like this:

```
1 cmlUpdate.setUpdate(new CMLUpdate[]{update});
2 WebServiceFactory.getRepositoryService().update(cmlUpdate);
```

In this codes, the node defined in the database will be updated, after the updated information is entered in the line 1 and the update operation is implemented in line 2.

(5) Lucene search engine: Alfresco development tool queries the data we need in the database system with Lucene search engine. Lucene, that provides search operations using the Lucene search syntax, is an open source information retrieval software library. The code used likes as follows.

```
1 String luceneQuery = "PATH:\"/app:company_home\"";
2 Query query=newQuery(Constants.QUERY_LANG_LUCENE,luceneQuery);
3 QueryResultqueryResult=WebServiceFactory.getRepositoryService().query(spacesStore,
query, false);
```

Here when the search range described as a directory is needed to be defined in line 1, the query results will be returned in line 3 after the search operation is executed in line 2. And also the conditional search with the keyword such as and and or can be used in Lucene grammar.

Design and realization of Alfresco database

1. Structure of Alfresco database

The database system of the micro-information system is constructed based on the Alfresco development tool, and the structure of the Alfresco database is shown in Fig.1. Storage and content of data is provided by persistent back-ends such as databases and file systems, in the meantime the application server houses both the Alfresco Application and the Alfresco API. An Alfresco Application provides a complete solution tailored for a specific area of Content Management such as Document Management (DM), Web Content Management (WCM) and Records Management (RM). The Alfresco API offers a set of reusable cross-cutting Content Management services such as content storage, query, versioning and content transformation. Furthermore all these services may be utilized by multiple applications.

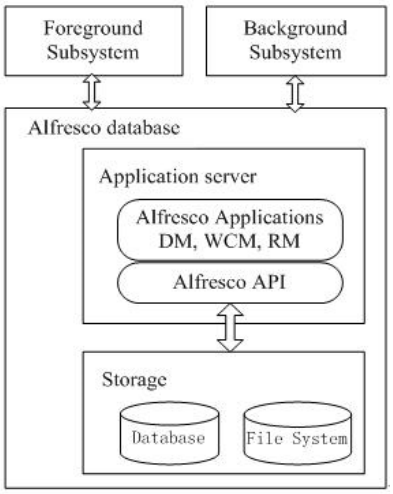

Fig.1 Structure of Alfresco database

2. The design of the micro-information system

(1) The foreground subsystem: In the micro-information system, the main role of the foreground subsystem is to demonstrate the content in the database system. After following the agreed protocol interfaces, the useful information from the database system could be gotten in the foreground subsystem, the MVC pattern of which is shown in Fig.2. Actually, the system manager does not need

to fully understand database techniques, while they just build the database by importing the required data of company in the management system through visualized operation which separates techniques and operation so as to reduce the technique requirement of manager.

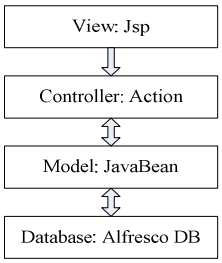

Fig.2 MVC pattern of the system

(2) The background subsystem: In the micro-information system, the background is designed to manage the system, in which the system administrators manage the database system and decide which would be shown in the foreground system. The basic function of the background subsystem in the Alfresco development tool is shown in Fig.3. In Alfresco database, both the database and the tables ,which include images, WIKI Encyclopedia and the market information database are stored as folders. The market information database contains information related to industry exhibition and some other latest information on the market.

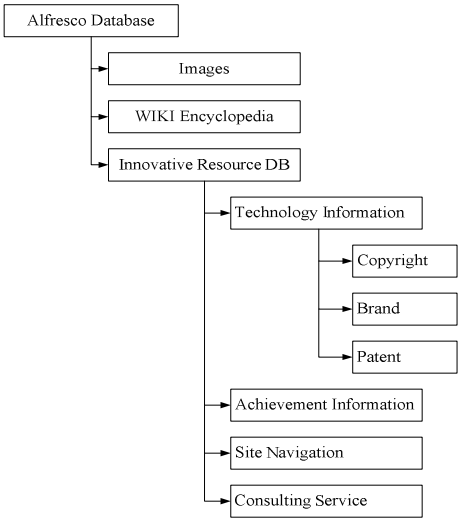

Fig.3 Basic function of background

(3) Design of Alfresco database: In this system, the databases, the data item of which can be either structured data, semi-structured data or unstructured data, such as images, sound and videos and so on, are designed as four groups, that are innovative resource database, market information database, enterprise technology database and user database. The innovative resource database contains the information such as patents, the latest researches which promote technological progress for enterprises, and so on. In the meantime the market information database includes information related to industry exhibition and some other latest information on the market, etc. The enterprise technology database consists of the information concerning recruitment, facilities rental and so on. In the user database there are all the information of users. The hierarchical contents of database system is shown in Fig. 4.

3. Realization of Alfresco database

(1) Table creation and editing: In Alfresco database development environment, it is convenient to create a table by visualized operations. First of all being token creating the table copyright that likes a table in other database as an example, after a new folder named Innovative_Resource_DB as one database of forth groups of this system in the Alfresco database development tool will be created after

log in the system as administrator, a new sub-folder named Achievement_information inside the Innovative_Resource could be created. Using the same method, the folder structure same as the relational database in other database system like SQL could be established successfully for the database of this system according to the hierarchical contents of database system in Fig. 4.

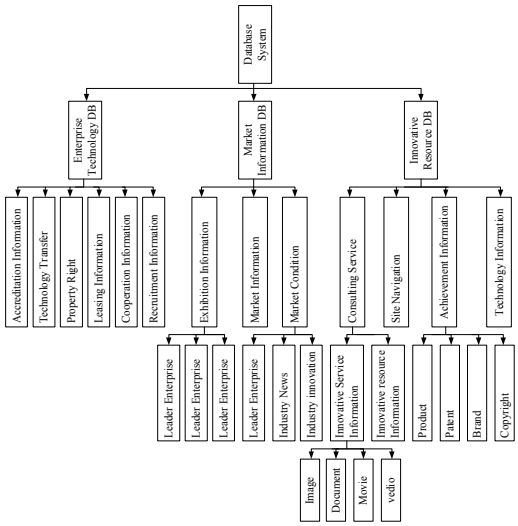

Fig.4 Hierarchical contents of database system

Editing a table is also convenient in Alfresco database by visualized operations too. For example in order to edit the table copyright, after logging in the system successfully and obtaining the permission to the table, we can create a file in the folder and edit the attribute of the file similar to the data item in traditional SQL.

(2) Data query: Suppose we want to search SONY in table brand, after getting permission to connect to the Alfresco database, we can use the following commands to realize this search function step by step like below:

To get permission to connect to the Alfresco database at first:

```
1  AuthenticationUtils.startSession("name", "passport");
```

To Set the search scope secondly:

```
1  path="PATH:\"/app:company_home/cm:InnoResource /cm:Achievement/cm:brand/*"";
2  factor1="@fdk\\:"+name+":\""+SONY+"\"";
3  luceneQuery = "" + path AND factor1;
```

To execute the query command thirdly:

```
1  Query query = new Query(Constants.QUERY_LANG_LUCENE,luceneQuery);
2  ResultSet resultSet = queryResult.getResultSet();
```

To obtain the query results at last.

```
1  ResultSetRow[] rows = resultSet.getRows();
```

(3) Data update: In order to update the attribute of the item SONY in table brand, the following steps can be used to update the data in the database after there being the permission to connect to the Alfresco database.

To get permission to connect to the Alfresco database at first:

```
1  AuthenticationUtils.startSession("name", "passport");
```

To set update information.

```
1  CMLUpdate update = new CMLUpdate();
2  update.setProperty(mySet("Name"， "Attributes"));
```

To set the node location.

```
1  update.setWhere(myWhere("File"， "Name"));
2  CML cmlUpdate = new CML();
3  cmlUpdate.setUpdate(new CMLUpdate[]{update});
```

To execute the update operation.

```
1  WebServiceFactory.getRepositoryService().update(cmlUpdate);
```

4. Superiority of Alfresco database

(1) Table operations: In order to create a new table in traditional database, the "CREATE TABLE" command, that should specify a set of attributes of the new table: the name of the table, the location of the new table, the name of each column in the table and so on, is needed in the professional database management system such as SQL. And the UPDATE statement to update records in a table is the same. Although all these operations can be done by the professionals, they can be easily implemented through visualized operations by customer only in the Alfresco database after designed by the professionals.

(2) Native file system support and Hot Backup: Alfresco database manages all kinds of content including documents, XML documents, photos, images, records, Web pages, or any other unstructured or semi-structured file. Users can get documents into and out of the repository easily. It needs to scale in order to support several hundred or more users and hundreds of thousands or even millions of documents with some percentage of growth each year. In this deployment, one Repository Server is designated as the Master host and another completely separate Repository Server is designated as the Slave machine. The application is hosted on the Master and as it is used, synchronous and asynchronous replication updates are made to the Slave i.e. the backup which remains in read-only mode. If for some reason, the Master breaks down, it is a relatively simple task to swap over to the Slave to continue operation. The Hot Backup of the system is shown in Fig.5.

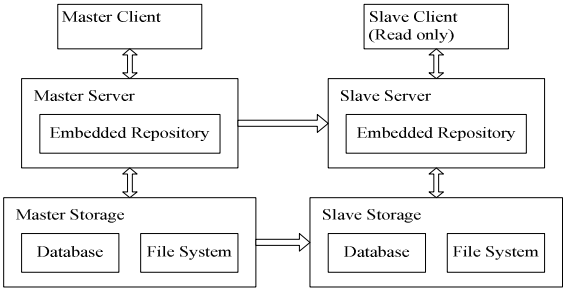

Fig.5 Hot Backup

(3) Other advantages of Alfresco database: In addition to above features described, there are many other advantages in Alfresco database. It gives fine-grained permissions which can be used to partition data, or to control access for "non power users" which can limit the damage they can do. It also owns high-level content management services such as transformation and meta-data extraction. It is deployable to any environment, including any application server, database and operating system. Besides these, Alfresco database supports workflow which can be used to streamline and automate manual business processes by letting the document management system keep track of who needs to do and what to a document at any particular time. The comparison between traditional database and Alfresco database is shown in Table.1.

Table.1 Comparison between traditional database and Alfresco database

	Traditional database	Alfresco database
Access Authority	Yes	Yes
Data Access Technology	JDBC	Alfresco SDK
Search Language	SQL	LUCENE
Data Encryption	No	Yes
Visualized Operations	No	Yes
Workflow support	No	Yes
Hot backup support	No	Yes
File System Support	No	Yes

Conclusion

In this paper, the Alfresco database of the micro-information system has been designed and realized. Construction and putting into operation of the micro-information system shows that the effect of Alfresco database is good in accordance of above ideas. Compared with traditional database system, Alfresco database provides better performances for construction of micro-information system for the small enterprises, which mainly reflects in higher security data, faster development speed and more stable performance. All these greatly improve data management and statistics of enterprises in specialized industrial townships. Through study and application of Alfresco database in this paper, it will be helpful for the developers to implement the management system with high efficiency.

Keywords: RBAC; control strategy; fine-grained access control; personalized operation; information system.

Abstract. Aiming at the deficiencies of traditional RBAC model, on the basis of studying of the models introduced in the literatures published, this paper puts forwards an improved model--MR-RBAC, including its concepts and design. This model is implemented by adding restriction strategy on the operation objects and data objects, assignment different privileges to different users via configuration mapping of functions and menus. The implementation and practice indicates that the MR-RBAC model not only simplifies privilege management, but also improves the system security and privileges management flexibility.

Introduction

Access control is an important means to realize safe access and operation on information system. Role Based Access Control, RBAC [1-3] is relatively mature and widely used in information system. With increasingly awareness of intellectual property and innovation, security for information system are more concerned and more requirements. Therefore, the researchers have been improving the mode of RBAC to realize better effect. Three major improving methods are as follows: (1) Aiming at operation targets of the model. Literature [4] proposed a RBAC authority management model by data limitation, adopting a kind of data limitation mode similar SQL to separate authority targets from data targets. (2) Aiming at role configuration of the model. Literature [5] improves the concept of role in RBAC, providing role property definition and validation mode based on property strategy. (3) Aiming at user operation in the mode. Literature [6] proposed correlation model of user interface and operation authority which enables automatic interface configuration according to users' authority.

Though the research improved the deficiency of RBAC, the requirement for authority management is not only complicated but changeable because of complex application and changeable management requirement. The above methods cannot solve complicated and changeable management requirement for authority distribution and are mainly reflected as follows: (1) Restriction on operation objects often leads to too high link between authority management and database structure, and increases coupling and extra risks like SQL injection attacks. (2) Improvements on role configuration simply integrate authority and separates resource range. But it cannot simplify configurations of operation interface, and can neither substantively change authority sets nor thin authority granularity. (3) Restrictions on users' operation, which merely relies on visiting pages. If data is operated by artificially constructing URL, it will lead to unauthorized use and less rigorous implementation. This paper puts forward an improved strategy based on RBAC model by regarding operation objects, users' role and users' operation as an organic whole to realize granularity control of object authority and automatically configure menu interface of different functions according to different roles and verify operation authority as well. Formalized definition of improved model (Menu and Restriction-RBAC model) is given in the paper and an implementation of general authority access control system---GAACS is provided as well.

MR-RBAC Model

Model Description. This model improves RBAC role by adding the menu configuration item to realize dynamic allocation of system operation authority. This model decouples authority management and system data. Through above improvements, users are assigned function privilege. Detailed model description as shown in fig. 1.

Related Concepts. The related concepts added in this model are illustrated here. Menus: menu set, personalized interfaces set of the access system operating. Objects: object set, the set of data and resources in the system. Operations: operation set, the set of functions that users can use. Op Restrictions: operation restriction set. Ob Restrictions: object restriction set, security level for example. RO: the mapping of many-to-many relationship in roles and operations. MR: the mapping of many-to-many relationship in menus and roles. OO: the mapping of many-to-many relationship in operations and objects. OPOR: the mapping of many-to-many relationship in operation restrictions and operations. OBOR: the mapping of many-to-many relationship in object restrictions and objects.

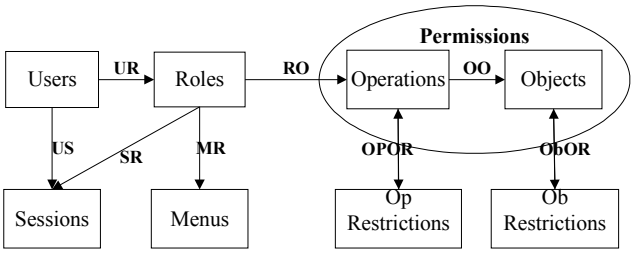

Fig. 1 MR-RBAC model

Model Implementation Approach. Here we present an approach for implementing MR-RBAC model that enables the user to reuse. We first give an overview of the approach and explicate its design in next section. The menu configuration realizes dynamic binding of authority and menu by configuring mapping relationship between role and menu first. Then it realizes dynamic binding of users and authority by configuring mapping relationship between user and role, and then realizes binding of user and menu. In order to avoid unauthorized operation on data by artificially construct URL, this model imposes further restrictions on user operation and examination on operation data. We take IP restriction as a user operation example. It can be realized by setting operation name in the database, corresponding IP validation and IP scope. The approach of data restrictions is similar to the operation restrictions. Dynamic binding of users and restrictions is realized by configuring mapping relationship between role and constraint. When performing an action, the model will verify the operation authority. Then to execute the operation on a data or not depends on whether the user has access to the operation of the data. Thus menu interface, restrictions on operation and restrictions on data, the three-layer authentication mechanism ensure the full restriction on user operation and guarantee system security.

Model Design and Realization

In this section we present the design of GAACS. The improved model consists of users' identification module, menu generation module, constraint strategy management module, authority management module and access control module.

Database Model Design. The database model design of general authority access control system is based on the thought of MR-RBAC model and analysis of module function demand. Fig. 2 only shows the main property of each related table in the model.

Function Design. Main functions of the system include user creation, menu generation, restriction verification and authority verification. Users' access control can be realized by organic organization of these functions.

User Creation. User creation is an essential function, which is the foundation of system operations. Firstly this function obtains user information to fill user object, then configures menu items and corresponding restrictions, lastly assigns corresponding role to the user.

Menu Generation. Menu as an entrance to system is very important. First acquiring all menu of the system from the database, and order according to the menu level, and then configure according to

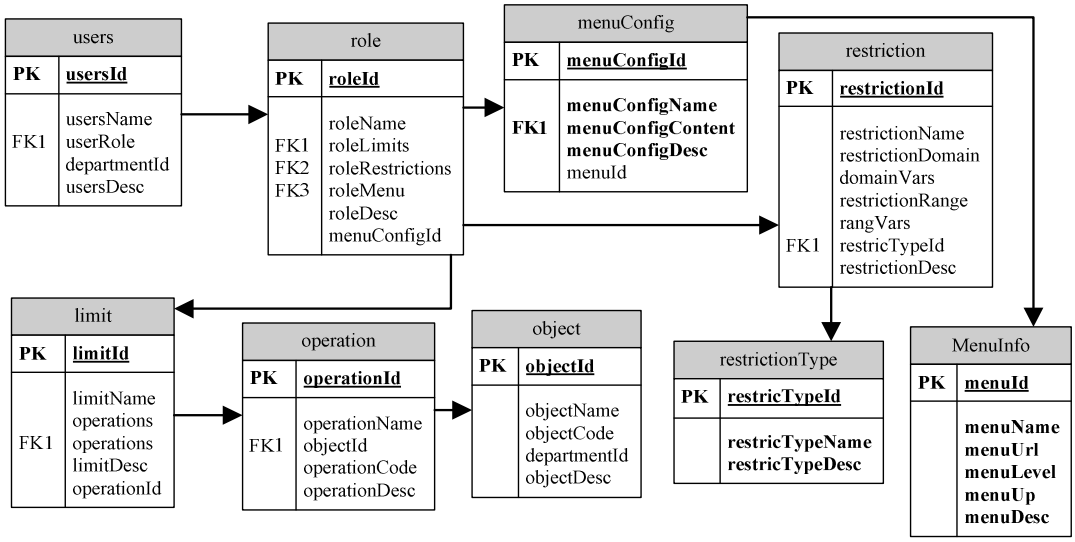

Fig.2 Database model of general authority access control system

subordinate relationship among menus. After all menus are configured, menu configuration data is persistently input menu configuration information list. When the system configures, menu configuration information corresponds to role, and then the generation of personalized interface is realized.

Restriction Verification. Restriction verification is introduced to manage access control for resource and data granularity management. Restriction strategy is a solution to strictly constrain system security level. Corresponding restriction information is acquired from user information after logging (the principle of acquiring restriction information refers to the implementation principle of above). When users implement a certain operation on an certain object, users' operation condition should be matched firstly. If the match is successful, it indicates that the user cannot implement the operation under this condition. It's the same case that if object match is successful, object cannot be operated under restriction condition. If the matches are all unsuccessful, corresponding object operation will be implemented.

Authority Verification. Authority verification is the core module of verification system and the control center of user access authority. First of all, acquire user information. If empty, enter logging page and acquire operation menu item corresponding to user and then dynamically generate user interface. Acquiring users' operation information after logging in and then load and intercept to judge whether it is in White List. If it is in White List, related operation is directly implemented. If not , verify user operation authority , operation object authority, operation restriction information and operation object restriction information. If there is authority and no related restriction, related operation should be implemented. Otherwise, unauthorized access will be reminded and the back. Authority verification flow chart is as Fig. 3.

Model Implementation and Application

Based on above design and approach, we develop a general authority access control system namely GAACS, based on Java EE 6.0 platform, use Oracle11g as database and MVC as system structure. GAACS is a Web application being deployed in Apache Tomcat 7.0 server. It is a non-invasive system, too. The front-end of this system is implemented with JSP combining Ajax technology to realize menu display. The back-end is coded base on Struts2 framework (using Actions to control user creation, menu generation, restriction verification and etc. and using interceptors to control authority verification) and Hibernate framework which is used to realize objectification access operation of Oracle database. Java reflection mechanism is used to realize decoupling of authority management

and thinning operation access granularity. Finally we use Spring framework to integrate each function module to complete all the GAACS functions of MR-RBAC model.

We use GAACS to conduct experiments to verify the effectiveness of MR-RBAC model. We apply this system to the Management Information System of College Communist Youth League and the network curriculum system of Java EE Framework Technology. Users can realize dynamic assignment of operation authority by configuring the mapping of menu items and user roles. They can add restriction strategy of operation and object to further guarantee system security. When operation management demands or data changing, users can directly adjust restriction strategy in authority configuration instead of readjusting program code. This improves authority configuration flexibility in the process of system operation and development efficiency of information system. The applications in the real-life information system development verify the effectiveness of our proposed model.

Summary

Access control is one of the most important parts of information systems. This paper puts forward an improved model--MR-RBAC model which can be reused in developing of various information systems. This model provides improvement strategies regarding operation object, user role and user operation as an organic whole instead of separated ones to realize granularity control of object authority. And it can automatically configure menu interface with different functions according different roles and verify operation authority. The implementation and successful applications indicate that the proposed model is achievable and the model proves to be effective in the practice and improves development efficiency of information system.

Research on ASP.NET-based task management platform

Fengwei Wang[1, a], Zhihong Xing[1,a] and Chen Liu[1,a]

[1]Liaoning institute of measurement, China

[a]250178551@qq.com

Keywords: task management; ASP.NET; Visual Studio 2005

Abstract. With constantly expansion of companies, more and more woks on communication become the managers' top issue. It is urgent to use computer technology to improve work efficiency and achieve of information sharing as much as possible. The managers need a platform to keep their information updated real-time, statistics tasks information at any necessary times, and the staff also need platform to record the task process, make schedule to alarm. Therefore, ASP.NET-based task management information system is designed and implemented. The system is developed with Visual Studio 2005 and SQL Server 2005, including task management module, file management module, schedule management module and background management module. With running in practical, it is proved that the system improved working efficiency greatly and implemented work information sharing effectively..

Introduction

With constantly expansion of companies, managers play more and more important role and undertake heavier and heavier work on the development and management part. The managers arrange a lot of tasks everyday, but the work progress cannot feedback to the managers in time and effectively. On the other hand, the feedback information and work records in the form of printing paper and copying paper are not easy to manage, find and statistics, which wastes a lot of human resources and greatly decrease the working efficiency. The root of the root-causes, it is not that the managers and staff are lazy on the job, but lack of an effective information communication and management platform which provides the foundation to achieve the right decision for manager.

Therefore, a ASP.NET-based task information management platform is designed and implemented based on the actual demands of work, which consists of task management module, file management module, schedule management module and background management module. With this system, the information communication between managers and staff improve effectively, which inevitable increases the working efficiency and management level.

Key Technology

.NET Framework. .NET Framework developed by Microsoft Corporation is a platform applied to Agile software development, Rapid application development, it is a programmed platform running in virtual machine which is based on the Common Language Runtime (CLR), and supports programming with Visual C#, Visual Basic, Visual C++ and so on.

The task management information system is developed with C# language and based on .NET Framework.

ASP.NET. As part of Microsoft .NET Framework, ASP.NET is a computing environment that simplifies application development in the highly distributed Internet environment. Besides simplicity, good usability, scalability, manageability as well as high efficiency, it is also known for its well-defined structure, good extensibility, powerful development tool support and security, and thus has become one of the most popular Web development technologies.

ASP.NET provides component-based, event-driven, programmable Web Form as a great simplification in programming. In addition, ASP.NET is capable of building Web Services. The main difference between ASP.NET and ASP lies in that the former requires compilation before execution

while the latter is interpreted during execution, so ASP.NET is much better in efficiency. In fact, we can consider the execution process of ASP.NET as CLR (Common Language Runtime) code working as an application that interacts with the front-end web browser and the middleware to accept requests from the user and output HTML stream to the user[1].

System Design

Workflow design and module design. The routine works in "Quality and Technology" department consist of many parts, such as QS (quality system) management, scientific research management, purchase management, train management and others, and work of each part consist of many items. Everyone in the department takes charge of many items which belong to different parts. On the other hand, there are many files on each item of work, including working guidance, common forms, and reference documents and so on. In order to increase the flexibility of system, the work items management is designed.

The system is developed to manage work in "Quality and Technology" department, implement effective communication between manager and staff. In this system, manager input work task first, and then staff input task progress according to actual work. After the task completed, staff click in the system, and manager input evaluation.

File management is also main function in the system, including attachment file management and reference file management. Firstly, everyone could query and download file to guide the work, and secondly, the manager could upload the reference file, and staff could upload the attachment file when report the process in the system. The file management flow is distinct and easy to execute.

Schedule management is auxiliary function of task management. Everyone could record and manage own schedule which will remind in time. Not only schedule can bind to work task, but also schedule can exist alone.

The function modules of system include task management, file management, schedule management, and background management.

(1) Task management module: publish task, input task process, edit task information, confirm the task has completed, evaluate and so on.

(2) File management module: upload reference file, delete file, search file and so on.

(3) Schedule management: make schedule, delete schedule, alarm at the homepage and so on..

(4) Background management: manage users information, manage task classed and file classes and so on..

Database design. Database design is a process to construct database structure. The system is developed with Microsoft SQL Server 2005 and based on the relational database. The entities in the system include task, task classes, file, file classes, schedule, evaluation, task process and others[2].

The relation between task and other entities is shown as Fig. 1.

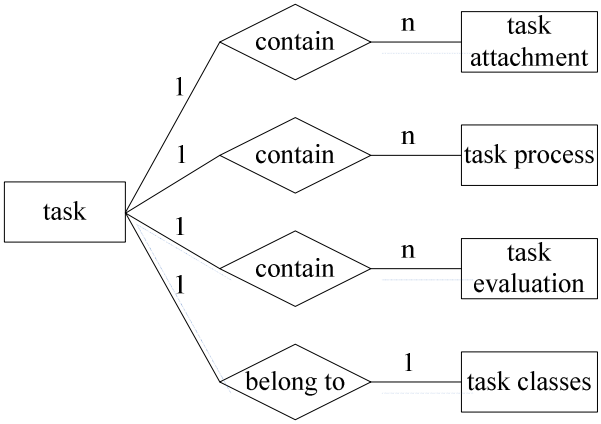

Fig. 1 The relation between task and other entities

System Implementation

Data Access Layer. To implement data access, a class named "DBOperation" is established and the data access string used is set in the file "web.config". The data access string is set as below[3]:

<appSettings>
<add key="ConnectString" value="server=(local);database=Task; UserId=sa; pwd = 123456"/>
</appSettings>

In the "DBOperation" class, many methods to access database are defined, such as:

(1) the methods open database connection and close database connection;
(2) the methods execute SQL command to insert, update, delete records;
(3) the methods execute SQL command to select records.

In addition, a class named "SQLString" is established to form SQL string based on the input values and validate the SQL strings which can increase the safety of database access[4].

Implementation of task management platform. Task management module include publish task, input task process, edit task information, confirm the task has completed, evaluate and so on. The flow chart of publish task is shown as Fig.2.

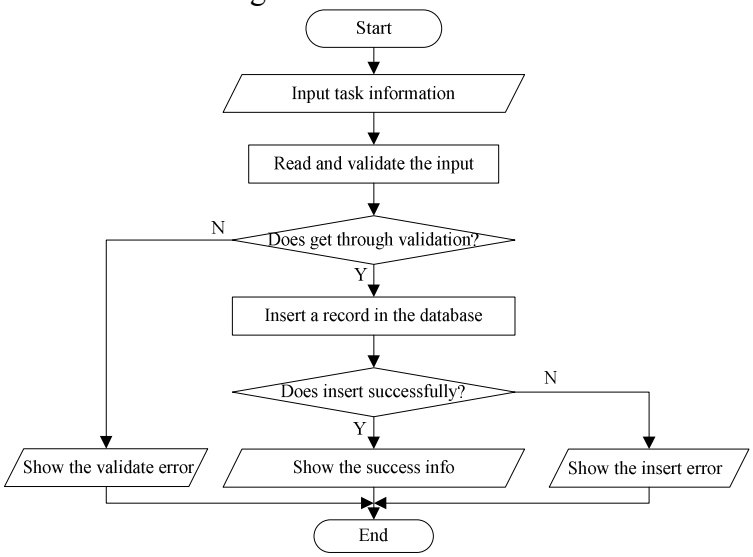

Fig. 2 The flow chart of publish task

System test and conclusion

The test is executed with each function by "Black Box Testing" method[5]. A lot of detail test prove that the system run with no breakdown in usual.

(1) The functions mentioned in the requirement document are implemented.
(2) The system is easy to use, easy to maintain.
(3) With running in practical, it is proved that the system improved working efficiency greatly and implemented work information sharing effectively.

Keywords: Body Area Network, Internet of Thing, Combination

Abstract: with the rapid development of body area network technology and the internet of things technology, makes the effective combination of these two techniques. Scientific connection method of study of this two kinds of techniques in this paper, to solve the core problems of these two kinds of technology association, and proposed solutions. The combination of these two techniques, and provide the technical support is widely used for applications of the Internet of things technology development and body area network.

1. Introduction

The Internet of things is also known as the sensor network, a vast network of the various information sensing equipment combined with Internet. The Internet of things is considered to be following the computer, the Internet, mobile communication, a new round of information technology revolution,it is the driving force of the core competition in the future information technology field and the commanding heights of industry upgrading. With the rapid development of information collection and intelligent computing technology,and wide use of the Internet and mobile communication network, large-scale development of the Internet of things and related industries the opportunity is becoming mature, developed countries such as America and Europe will network as an important area of future development. Our country began the research of the Internet of things as early as ten years ago, formed a certain scale of the industry, and has made certain discourse power in international standard setting, the application of Internet of things is initially started.

Biological recognition in twenty-first Century was named one of the ten major high-tech. As body communication technology of biological recognition technology, as early as in 1996, IBM first unveiled the human communication technology. Now study abroad, to the skin surface of human body as the data bus HAN (HAN, Human Area Network) technology has been gradually moving towards the commercial application. Japan has developed a data bus in communication technology with skin and skin 20CM distance. China has started, the scope of its application are remote medical treatment, digital intelligence, automatic safety communication, identity authentication etc.

In recent years, with the development of microelectronic technology, the wearable , the implantable and can invade of service device has appeared: for example, worn on a finger of quality sleep blood oxygen sensor, wrist watch type glucose sensor, watch type measuring device, sleep physiology checker, implantable identification components etc. If there is no body area network, these sensors and actuators are all can work independently, to bring their own respective communication components, so the communication resources can not effectively use. Visible, body area network and the Internet of things is a combination of natural in technology.

2. Wireless Body Area Network

BAN (BAN, Body Area Network) is usually regarded as a solution, wireless standards organizations and IEEE are in the development of BAN technology.Sensors collect information through wireless transmission to the terminal processor. Then the processor through the traditional data network (for example: Ethernet, Wi-Fi or GSM), will all send information to the specified server. Sensor of BAN will generally require high precision, low power signal processing level, and require a wireless connection.BAN is the sensor system to a configuration, low cost, low power and high reliability. The packaging and operation must be sterile for human peripheral or internal. In addition, the wireless communication must be enough robust to prevent the RF interference in various environments,for example: Wi-Fi network, microwaves and cordless phones.

BAN design should meet the following conditions:

(1)Low power consumption and low current consumption. Use time of the battery should be considered in design of BAN node.

(2) High reliability. The system must be able to provide sufficiently high data accuracy and reliability.

(3) High security. The BAN node must have adequate safety measures, to protect patient privacy and prevent hacking.

Red Tacton technology is a kind of wireless transmission technology of BAN technology, to transmit data through the skin of the human body. Red Tacton is used in weak electric field, so wear or implanted in the body of Red Tacton transmitter produce much weaker electric fields on the surface of the human body, the human skin as the data transmission channel and media.

In order to develop an suitable low power consumption device and optimized communication standard for BAN application, IEEE has developed the IEEE802.15.6 standard.Compared with the existing standards, IEEE802.15.6 has many advantages. It focuses on the short distance, low cost, low power consumption and low implementation complexity. IEEE802.15.6 standard on the PHY (PHY, physical layer), MAC (MAC,media access control layer) protocol and security layer are defined.

IEEE802.15.6 consists of a PHY layer and a public MAC and a security layer.The PHY layer is designed to meet the needs of different data rate requirements of the application, it is divided into three bands:narrow band, ultra wide band and human body communication band. Its target communication distance is 3 meters,support 100kbit/s to various data between 1Mbit/s rate.The maximum power consumption for the 3mA.

3 The Internet of things Modeling

The internet of things not only provides the connection of the sensor, its also has the ability of intelligent processing, to implement the intelligent control of objects. The internet of things sensor and intelligent processing combination, the use of cloud computing, pattern recognition and intelligent technology, expand its application areas.

The internet of things is a information carrier based on the internet and the traditional telecom network etc. It makes all independently addressable physical object to realize interconnection. The related technology of the Internet of things related to many fields,its technology often has the application demand in different industries[1], the internet of things can be roughly divided into three layers.

Among them, the perception layer is responsible for perception the physical world data information, With gathering information on the real world or RFID terminal sensor node.

The network layer is responsible for solving the perception layer for data transmission problem, and to provide the service to the upper layer.

The application layer is responsible for processing information and user interface management. Through analysis and processing of sensory data, provide the application interface and support services for the user. The current typical applications such as logistics monitoring[2][3], furnishing asset statistics[4], intelligent Home[5]， remote meter reading[6] etc.

Hypothesis the communication channel is a N independent channel,let X and Y are independent of each other and mean value is 0, variance σ^2 of Gauss random variables, received terminal signal can be expressed as:

$$Z=Xi+Y \tag{1}$$

Among them,the joint probability density function for X and Y:

$$f_{(x,y)}(x,y)=\frac{1}{2\pi\sigma^2}e^{-\frac{x^2+y^2}{2\sigma^2}},-\infty<x,y<\infty \tag{2}$$

Hypothesis the signal phase is θ, and the amplitude is ω,according to the formula (2) may be marginal probability density function of phase and amplitude :

$$\begin{cases} f(\theta) = \int_{-\pi}^{\pi} f_{(x,y)}(z,\theta)d\theta = \frac{\omega}{\sigma^2} e^{-\frac{\omega^2}{2\sigma^2}}, 0 < \omega < \infty \\ f(\omega) = \int_{0}^{\infty} f_{(x,y)}(z,\theta)dz = \frac{1}{2\pi}, -\pi < \theta < \pi \end{cases} \quad (3)$$

Then using formula (3) to calculate the amount of the received signal average value:

$$E(\omega) = \eta \int_{0}^{\infty} \omega f_{(x,y)}(\omega)d\omega = \eta\sqrt{\frac{\pi}{2}}\sigma \approx 1.26\sigma * \eta \quad (4)$$

Among them, η is model correction coefficient.

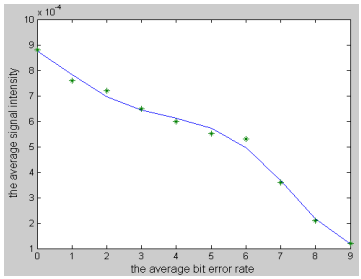

Figure 1. Relationship between signal intensity and the bit error rate

This paper did a study on the relationship between the signal intensity and the bit error rate, shown in figure 1 is the signal in different intensity through the channel the bit error rate. It can be seen that the signal intensity increased but the bit error rate reduced gradually. There is requires the channel transmission code accuracy in BAN protocol. As can be seen from figure 1, as long as the signal strength is large enough, maybe satisfy the requirements of the BAN protocol agreement.

4 Conclusion

The internet of things is a new technical system of multiple information fusion, as a connection Things—Things the relationship between network, include a variety of network, has a key role in communication technology and wireless sensor network. The body area network and the Internet of things combined has important practical significance.

A SVM Reliability Evaluation Framework for the Component-based Web System

NIE Peng[1, a]

[1]Jiangxi University of Finance and Economics, Nanchang, China

[a]zeanet@163.com

Keywords: component; Web system; reliability evaluation; support vector machine

Abstract. In the reliability evaluation studies of the component-based Web system, the stated-based models and the path-based models suffer from the high time-consumption for the high complex web structures. In this paper, a SVM Reliability Evaluation Framework for the component-based Web system (SVMREF) with a low computational complexity is presented. SVMREF employs the Web component reliabilities as the SVM inputs and outputs the final reliability evaluation after the well-trained learning process. Our proposal has a low evaluation complexity and outperforms the state-based model and the path-based model. The experiment results and the analyses show that SVMREF has a better reliability evaluating convergence and SVMREM is evidently lower than the contrast models when the Web system structure is complex .

Introduction

With the development of software technology, software grows both in functions and complexity. Adapting to the trend, the ideas of the component-based software design and reuse have been widely used in the enterprise information platform constructions and become one of the important methods in software development. The enterprise Web application is an instance of the component-based idea. The Web application is usually divided into several subsystems, and the subsystems are split into the components charging different functions. The white box models are used in the component-based Web software reliability evaluation. Further more, the white box models includes the state-based[1-3] and the path-based[4-5].

A SVM Reliability Evaluation Framework for the component-based Web system (SVMREF) is proposed for the component-based Web systems in this paper. Our proposal obtains the Web component reliability based on the system logs and learns the implicative complex knowledge between the component reliability and the overall software system reliability. Based on that knowledge, the final evaluated result is output.

The rest of this paper is organized as follows. Section 2 presents the related works on the Web component-based software evaluation. The SVMREF notations, definitions are presented in Section 3. Our proposed model SVMREF in detail is presented in Section 4. Section 5 gives the experiments and the performance analyses. Finally, Section 6 concludes this paper.

Related works

Musial[6] proposed a heterogeneous architecture reliability model based on the discrete time Markov chain for service-oriented applications. Eaton[7] designed a learning mechanism that inductively acquires knowledge of tag support criteria based on observed samples of accessible and inaccessible web page source code. Leticia[8] gave a methodology for improving the reliability of web-based software systems by the traditional analytical model. Karambir[9] summarized the relevant aspect of reliability issues and estimated the reliability of Web application using Markov model. Rohini[10] used the doubly stochastic model to access the website current reliability.

The major drawback of Markov Model is the explosion of number of states as the size of system increases. The resulting models are large and complicated. The analytical models suffer from the model assumptions[11].

SVMREF notion

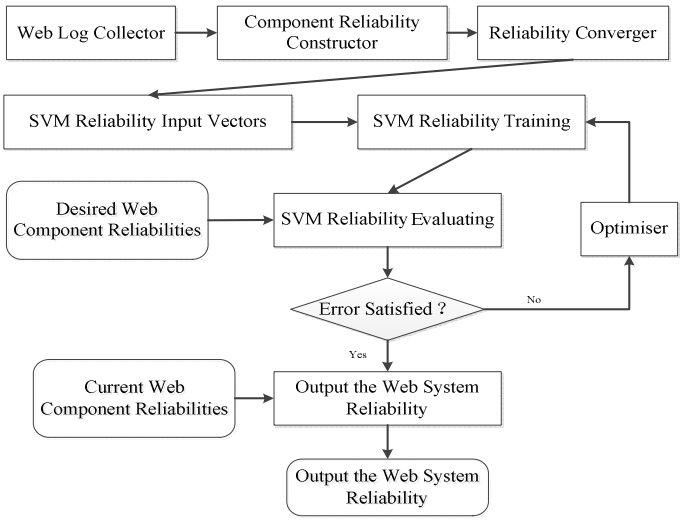
Notation

N_i	a specific component	R_i^k	the reliability of N_i on the k-th execution
R_s^k	the software system reliability on the k-th execution	R^k	the software system reliability set on the k-th execution
R_T , R_E	the observed software system reliability and the evaluated reliability	ε	the error between R_T and R_E

SVM reliability evaluation framework

In our proposal, we employ SVM based on the component historical reliability to construct the software system reliability evaluation. Fig. 1. presents the overview of SVMREF. The elements in the SVMREF are introduced in detail as follows.

- Web log collector analyses the Web logs, and collects the faults logged in the system.
- Component reliability constructor constructs the component reliabilities according to the result given by the Web log collector.
- Reliability converger reports the component reliabilities to the reliability database center.
- SVM Reliability Input Vectors are set up based on the reports from the reliability converger.
- SVM Reliability Training uses the reliability input vectors as its input, and trains itself to learn the implicative complex knowledge between the component reliability and the overall software system reliability.
- SVM Reliability Evaluating uses the desired Web component reliabilities and outputs a abecedarian value. The SVM error between the real value and the evaluation are checked, and SVM is trained again until the SVM error is minimized to a given value.



- SVMREF loads the current Web component reliabilities to evaluate the Web system and outputs the evaluation result after the SVM is well-trained.

Figure 1. Overview of SVMREF

Assume $\{((R_1^1,\cdots,R_n^1),R^1),\cdots,((R_1^k,\cdots,R_n^k),R^k)\}$ be the given training datasets where each $(R_1^i,\cdots,R_n^i)$ shows the SVM reliability training data vector in the *i*-th iteration for the nodes from 1 to n. R^i is a corresponding target system reliability value in the *i*-th iteration where $i=1,\cdots,k$. k represents the iteration number of the software reliability testing. The support vector regression solves an optimization problem:

minimize: $\frac{1}{2}\|w\|^2 + C\sum_{i=0}^{l}(\xi+\xi^*)$

$$\text{subjected to } \begin{cases} R^i - \langle w,(R_1^i,\cdots,R_n^i)\rangle - b \le \varepsilon_i + \xi \\ \langle w,(R_1^i,\cdots,R_n^i)\rangle + b - R^i \le \varepsilon_i + \xi^* \\ \xi_i,\xi_i^* \ge 0 \; i=1,\cdots,l \end{cases} \quad (1)$$

where ξ_i is the upper training error (ξ_i^* is the lower) subject to the ε insensitive tube $R^i - \langle w,(R_1^i,\cdots,R_n^i)\rangle - b \le \varepsilon$. The parameters which control the regression quality are the cost of error C, the width of the tube and the mapping function ϕ . The constraint simply that we would like

to put most data $(R_1^i,\cdots,R_n^i)$ in the tube $R^i-\left\langle w,(R_1^i,\cdots,R_n^i)\right\rangle-b\le\varepsilon$. If $(R_1^i,\cdots,R_n^i)$ is not in the tube, there is an error ξ_i or ξ_i^* which we would like to minimize in the objective function. For the traditional least square regression, ε is always zero and data are not mapped into higher dimensional spaces. Hence, SVM is a more general and flexible treatment on regression problems. Dibike et al. demonstrated that the radial basis function (RBF) outperforms other kernel functions, and is expressed as

$$k(R_i^j,R^j)=\exp\{-\gamma\left|R^j-R_i^j\right|^2\} \tag{2}$$

where γ is the parameter of RBF which gives the width of the kernel. In general, γ varies from 0 to 1. The SVM model used herein has three mutually dependent parameters, namely C,ε,γ, thus changing the value of one parameter changes the other parameters too. A common way to estimate the SVM parameters C,ε,γ is to separate the data into two sets, namely a training dataset and a validation dataset. The prediction accuracy of this validation dataset reflects the accuracy of the model, and SVM parameters which are able to give minimum prediction error are considered to be the optimal parameters.

Experiments and performances

The Online Course Choosing Web System(OCCWS) in Jiangxi University of Finance and Economics was employed for the SVMREF experiments and the performance analyses. The classical stated-based CUORM model and the path-based HARAM model were used as the baselines for SVMREF software reliability assessment.

OCCWS

The component list of OCCWS and the visit statistics are shown in Table 1.

Table 1 OCCWS components list and visit statistics

Function	Component ID	Description	Visits	Cumulative errors
User Login	C_1	Login interface	26430	0
	C_2	Login capacity controller	1163327	3025
	C_3	Authenticode creator	182227	1002
Certificate	C_4	Certification	697246	1046

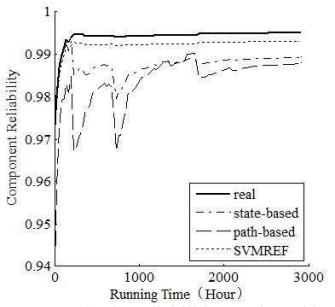
$P_{3,1}$=1	$P_{4,5}$=1	$P_{5,6}$=1	$P_{6,7}$=0.5868
$P_{6,15}$=0.4132	$P_{7,8}$=0.5063	$P_{7,9}$=0.4935	$P_{7,15}$=0.0002
$P_{8,9}$=0.7953	$P_{8,14}$=0.1896	$P_{8,15}$=0.0151	$P_{9,10}$=0.236
$P_{9,15}$=0.764	$P_{10,11}$=0.875	$P_{10,15}$=0.125	$P_{11,12}$=0.7014
$P_{11,15}$=0.2986	$P_{12,13}$=0.9726	$P_{12,15}$=0.0274	$P_{13,8}$ = 0.9834
$P_{13,15}$=0.0166	$P_{14,8}$=1		

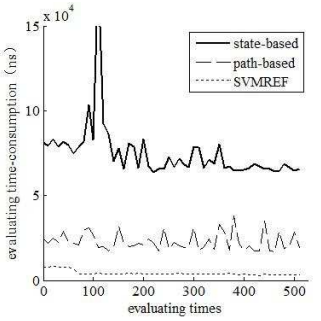
$P_{n,m}$ presents the reliability transition probability from C_n to C_m

Figure 2. OCCWS workflow

The reliability curves evaluated by CUORM, HARAM, SVMREF and the observed real reliability in OCCWS are shown in Fig. 3-(a). The evaluating time-consumptions are show in Fig. 3-(b).



(a) the reliabilities evaluated by CUORM, HARAM, SVMREF



(b) the evaluating time-consumptions

Figure 3. Reliability evaluated curves and the evaluating time-consumptions

Model comparisons

For the model comparisons, the relative error (ε) as Eq. 3 is used to evaluate the accuracy of models.

$$\varepsilon = \frac{R_T - R_E}{R_T} \tag{3}$$

R_T denotes the observed reliability, and R_E alternatively uses R_{HARAM}, R_{CUORM} or R_{SVMREF}. Average $|\varepsilon|$ is used to calculate the average relative error in the experiments of OCCWS. Table 2 presents the evaluated reliability comparisons in OCCWS.

Table 2 Evaluated reliability comparisons for OCCWS

$\lvert\varepsilon\rvert$						Average $\lvert\varepsilon\rvert$		
R_{HARAM}		R_{CUORM}		R_{SVMREF}		R_{HARAM}	R_{CUORM}	R_{SVMREF}
min	**max**	**min**	**max**	**min**	**max**			
0.010	0.034	0.011	0.015	0.000	0.008	0.011	0.007	0.001

OCCWS have been executed more than 500 times to reach their stable reliabilities. As Table 2 shows, in most cases, the average $|\varepsilon|$ of R_{HARAM} is much greater than the other two. The accuracy of R_{CUORM} is relatively smaller than R_{HARAM}, around 1% on average of $|\varepsilon|$. However, the cost is the complexity of $O(n^3)$. The reliabilities evaluated by the proposed model SVMREM are closer to R_T than those of R_{HARAM}, and R_{SVMREM} around 0.1% $|\varepsilon|$ on average.

Time-consuming comparison

Fig. 3-(b) shows that HARAM has a less time consuming. However, HARAM suffers from nesting one sub-structure within another sub-structure. As the software system becomes complex, such nesting sub-structure combination makes HARAM rather complex. SVMREF benefits from its

low computing complexity and outperforms the other two models in the reliability evaluation for the Web system.

Conclusion

This paper presents SVMREF for the reliability evaluation for the Web system constructed by the components. SVMREF enhances the time-consumption and outperforms the state-based and the path-based models in the evaluation accuracy. Our analysis and experiments show that the proposed scheme consumes less time and has a better reliability accuracy in the Web reliability evaluation.

The Design and Realization of Virtual Editing Environment for News Release

ChengJiong-wang

School of computer engineering WeiFang University WeiFang China

wcjsdwf@126.com

Keywords: Virtual editing, News gathering and editing, Network officing.

Abstract. As the development of modern information technology, the digitization, mobilization and networking of working environment have become the general trend, directly from which the virtual editing environment cooperatively supported by the computer comes. The realization of mobile officing and home officing through VIEW makes the editing of news agencies virtual and links news gathering and editing with network to fully enhance the efficiency of news publishing and provide better working environment for editors and reporters.

1. Background of the Subject

As the constant progress of the society and rapid development of the technology, the social value and economic value of news information have been widely recognized and higher demands for timeliness of news are made. How to enhance the working efficiency of news gathering and editing process has become another focus in news publishing world. Establishing news gathering and editing all-in-one system through modern information technology to realize the digitization of news gathering and networking of news releases greatly enhance publishing efficiency. However, as one of the key links for news publication, relay mode in composition system and manual processing mode in layout planning, layout proofreading, layout editing, layout delivery and layout issuing have become the main bottleneck for enhancement of efficiency. Moreover, it is hard to develop new generation layout production system based on network environment for single machine system and news gathering and editing network which has become an urgent mission[1][2][3].

In recent years, modern information technologies such as computer, exchange network and multimedia database have developed rapidly and entered realization stage, influencing people's life styles and working styles and promoting the formation of many a brand-new conceptions such as home officing, mobile officing, video conference and computer supported cooperative work-CSCW, besides information consumer electronic such as information household appliances, intelligence terminal, VOD, WebTV are in line with the developing trend[4][5].

Using information technologies to create efficient and comfortable working environment and living environment has become the theme of information development, traditional working geographical attribute is vanishing gradually, and virtual working environment characterized by digitization, mobilization and networking is going to be the main stream. Above all, all the conditions that using modern information technologies to reform news publication process, fully enhancing the timeliness of news and providing convenient and fast digital working environment for editors and reporters are ready and time is propitious.

2. System Demands

Layout production is the one main influencing efficiency and quality in the process of news publication; it includes layout planning, typesetting, proofing, proofreading, submission and issuing. Different from gathering and editing, it includes not only serial work flow process but also collaborative parallel processing by dynamic working team comprising responsibility editor, operator,

director and chief editor, which is a layout design and editing process according to different operation authority. In details it has the following functions:

Selecting a Template. It is mainly used to complete the traditional layout production, including the following aspects:

Layout Planning. It is divided into two steps: the first one is to draw up the framework of news releases and advertisement regions by general editing office; the second one is to partition the layouts according to the news by responsibility editor to confirm the position and relevant attribute and to confirm the advertisement arrangement according to the demands of the subscribers by advertisement editor[6].

Regional Subject Editing . Set up regional subjects and select and post the picture-text news from the issuing ones. Typeset according to the confirmed attribute (font, size) and decorate for readability and aesthetic (lace, underpainting). Regional contents editing includes adding, deleting, revising and changes of regional position, sizes and decorations.

Collaboration Function. Using video, audio, e-mail and electronic white board for multi real-time collaboration in the process of layout production, which includes: parallel processing of different regional subjects in the same layout and interactive processing of the same regional subjects by different persons.

Controlling Function. It is used to control the layout quality and layout processing procedure.

Layout Processing Procedure Monitoring. It can real-time track the regional subject processing and know the schedule of the whole layout at any time and offer relevant comments.

Layout Proofreading. Using network printing device to output layout (also called proofing) and evaluate the output effects, including fonts quality, color quality and layout arrangement etc.

Another important one for layout proofreading is to check the news release itself, including words, phrases, structure and logic, besides the factuality and legality, in order to guarantee quality[7].

Proofreading requires the support of news material management and service system.

Layout Submission and Issuing. According to the work process, designate authority for different persons, and layout shall be submitted for check step by step after completion, at last signed and issued by chief editor. The final version could be in the form of PS, EPS, PDF and HTML. The layout could be handed for printing and sent to different printing agencies through Internet or satellite and could be published on the Web in the form of electronic newspaper. The sign and issuing of the layout requires the support of digital signature technology.

Revision Process Record. Make detailed and correct record of revision on layout elements in the process of layout production for inspection.

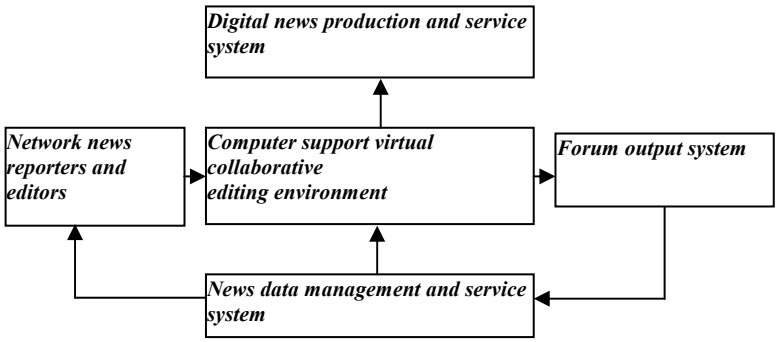

Fig.2 The Relationship of Other System in View System and News Press Process

Maintenance Function. Complete the management of different persons and their access rights and back-ups of core data. Especially the maintenance of font library makes the layout results independent of specific output platform for better applicability, which is the difference between the east and west languages.

Non-function Demand. Besides above function demands, VIEW has following non-function demands:

Good Integration. Integration has two aspects:

VIEW system could be an independent running entity, at the same time it also should combine with news gathering and editing system and output system.

VIEW system is only a basic frame system and mainly used for organization and management of layout. Some regional subjects of different type can be completed by relevant components which can be integrated with frame system as required to simplify the complexity and guarantee the openness of system to meet the individual needs of different users.

Convenient Operation Mode. Layout production process is a highly interactive one. Design quality of interactive process and interface influence operation efficiency directly and are closely related to the work intensity, so convenient operation mode is the key point for success.

Manageability. Mobile officing and home officing editorial office supported by VIEW is not geographical conception but a dynamic working team on the Net. People may be working everywhere, traditional software management is no longer suitable for the work management and new software structure is taken for zero management of working platform. Available technologies right now include CORBA, JINI and DCOM.

High Safety and Reliability. Due to the particularity of news publishers, the safety and reliability are demanding. It requires strict operation authority for different persons to unify the power and responsibility, and also to guarantee the printing and publication in time. Every technology should be used in the system to guarantee the normal operation of software and hardware devices, even under extreme circumstance; single machine is able to be used to complete the layout production.

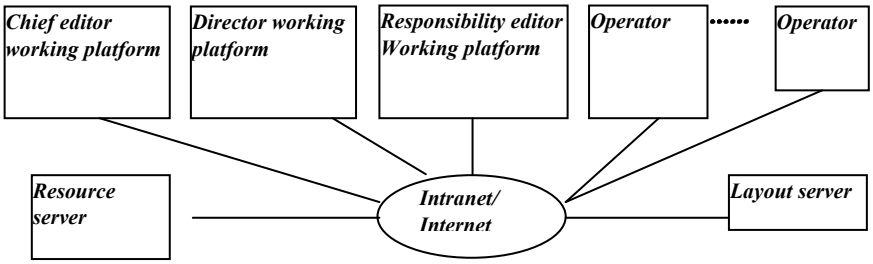

Fig.1 The system structure

3. The System Structure

The structure of virtual editing system is as Fig.1. The relationship of other system in VIEW system and news press process is as Fig.2.

According to the business features of news press, collaborative roles are operator, responsibility editor, director and chief editor. Every role corresponds to one working platform to complete his function in his own right management.

The layering model of virtual editing environment is as Tab.1

TABLE1 THE LAYERING MODEL OF VIRTUAL EDITING environment

Chief editor working platform	Director working platform	Responsibility editor working platform	Operator working platform
Editing environment general components			
Video, audio	Electronic white board	E-mail	Components integration support	database
Operating			
Hardware Platform			

Operator Working Platform. The platform is mainly used to make layout subjects, including news posting, subject decoration, contents editing and layout submission to the responsibility, according to responsibility editor's design plan.

Responsibility Editor Working Platform. It is mainly used to complete layout planning, layout check, layout elements revision, region locking and layout submission. Real-time alternation between responsibility editor and operator is the most frequent.

Director Working Platform. It is mainly used to monitor the layout schedule, layout sign and issuing and submit the completed layout to the person in charge.

Chief Editor Working Platform. It is mainly used to read the layout, check important news releases and general effect and offer revision comments to responsibility editor (including the change and revision of layout elements), even adjust or revise the layout and its elements directly if necessary.

Besides above functions, every platform supports on-line news material search.

4. Difficulties In System Research

The Research on virtual editing environment collaboratively supported by computer consists of information processing technologies such as computer, exchange network, multimedia and database and psychology and behavior, which is a very complicated information processing system, mostly in following aspects:

Establishment of Editing Environment Model. It includes the recognition in editing process, drawing in behavior model and information procedure establishment driven by roles. The establishment of editing environment model is the basic of system research, which is involved in decomposition in business process and requirement of behavior mode. Due to the relationship with psychology, it is hard to establish a stable model.

Materials Distribution and Management. VIEW system is different from the normal shared application, which can not be easily controlled by "virtual pen". Fully considering network reliability and transport efficiency, make a reasonable compromise between concentrated materials management mode and distributed materials management mode to guarantee the conformity and completeness and enhance transport efficiency.

Establishment of Collaboration Conversion Model. For many different roles are involved in VIEW system, the operations influence each other and single working platform includes many parallel processing, unified conversion model must be taken into consideration to guarantee the stability of the whole system at the time of parallel processing for order and efficient operation of the system.

5. Conclusion And Expectation

News press model consists of news gathering and editing, network composition, parallel output, digital news production etc. We put forward the conception of virtual editing environment and complete it in network environment. The spread and application will improve the modernization of news press technologies [8].

Reliable Node based Multipath QoS Routing Protocol on Opportunistic Networks

Xuebin Ma[1, a], Liting Wang[1, b] and Zhenchao Ouyang[1, c]

[1]Department of Computer Sciences Inner Mongolia University Hohhot, China

[a]csmaxuebin@imu.edu.cn, [b]wanglt99@gmail.com, [c]ouyangkid@gmail.com

Keywords: routing; multipath; QoS; reliable node; opportunistic networks.

Abstract. Opportunistic networks are similar to the mobile ad hoc networks (MANETs) that does not have fixed infrastructure, and the messages can be transmitted by nodes in a "store - carry - forward" approach. The mobile nodes randomly move, which result in a constantly changed network topology and frequently interrupted link. Thus, multipath routing has been proposed to improve the stability of link, extend path lifetime and reduce packet loss rate. The paper first analyzes the traditional multipath routing protocol and its path selection theory, and then investigates quality of service (QoS) metric to improve transmission efficiency of opportunistic networks, and finally proposes a reliable node based on multipath QoS routing protocol, named as RNMR. In RNMR, the stable path contains primary path and two backup paths. The primary path consists of reliable nodes and intermediate nodes, and the two backup paths are formed by two disjoint sub-paths selected from two adjacent and reliable nodes. By comparing with the backup source routing (BSR) protocol and greed -based routing (GBR-WB) protocol, the paper proves RNMR protocol has longer path lifetime, deliver rate and relay are also improved.

Introduction

Opportunistic networks are class of mobile ad hoc networks (MANETs) and do not necessarily have a complete path between source and destination. An opportunistic network utilizes encounter chance of mobile nodes to realize communication each other [1]. Delay tolerant network (DTN) [2] is first proposed by tolerant network research group for communication of interplanetary network (IPN), and its main objective is to support inter-connection of heterogeneous network which has intermittent connectivity, large delay and high error rate, such as Internet and sensor network, mobile ad hoc network (MANET). Thus, the opportunistic network can be treated as a wireless ad hoc network with the general characteristics of the DTN network.

The traditional MANET [3] routing protocol exists at least a complete end-to-end path when transmits messages. At some point, MANET network may be divided into unconnected sub-regions. When source node and destination node are in different domains, MANET routing protocol cannot find the path to the destination node. However, this does not represent without any communication. Since the nodes are moving, and two nodes within radio communication range can exchange data in a hop-by-hop method. Thus, in opportunistic networks, the network is not required to be fully meshed which is more suitable for ad hoc network. Opportunistic networks take the "storage - carry - forward" approach as the means of information transmission. Because the opportunistic networks rely on nodes to complete the end-to-end message transmission, and thus it is necessary to consider three questions in the information transmission process: reliable node selection, transmission reliability control and buffer management and scheduling.

Through the deep research, extensive usage of the MANET and Wireless Sensor Network (WSN) [4], opportunistic networks deny routing model in the traditional network, and improve the stability of path. Although Epidemic routing protocol [5], Spray and Wait routing protocol [6] that are based on encoding routing protocol can reduce TTL, they can cause much network overhead and ignore to improve QoS [7]. Probabilistic Routing Protocol using History of Encounters and Transitivity (PROPHET) is a kind of probabilistic routing protocol, which can transmit messages by encountering

probability of nodes. There is a shortcoming that it cannot guarantee messages successfully to transmit from source to destination.

In order to improve the stability of the routes and QoS of network, this paper proposes a reliable node based on multipath QoS routing protocol (RNMR). We determine the zone of reliable nodes in the research workplace, and select reliable nodes by battery model. Then we can use encountering probabilistic model to establish one major path and two backup paths. At the same time, there are two disjoint sub-paths between adjacent reliable nodes. RNMR routing protocol has many advantages: (1) the primary path is the shortest path, which composes of reliable nodes and intermediate nodes; (2) when major path interrupted, backup paths can continually transmit messages; (3) it can reduce routing overhead. Through theoretical analysis, RNMR routing protocol can acquire longer path lifetime so that improving the path stability and QoS.

The rest of this paper is organized as follows: Section II describes RNMR routing protocol in detail. Section III discusses the performance of the RNMR protocol through theoretical analysis. Finally, we conclude the characteristics of RNMR.

RNMR routing protocol

Initial position coordinates of the nodes in the research scene are determined by the Global Positioning System (GPS). We use power model to find the reliable node for message transmission, and to utilize encountering probability mode for route discovery. In addition, mobility model is used to determine link expiration time of nodes, and confirm expiration of paths.

Reliable node region. We analyze the mobile of students at school; mobile nodes have certain regularity. We record initial position of nodes and collect position of others.

Reliable node selection. We will assume a university as the research scene and choose one of the buildings within the university as a region. We draw a circle with the centre and width of the building. It is the size of the selected area. At the same time, we choose a small circle again from the selected circle. Assume O and R represent the centre and radius of the circle, respectively. The small circle is the selection area for reliable node whose radius is r (r=0.5R). The initial position of every node is acquired by GPS, and new position of these nodes is determined by mobility node at time t.

Power model. In order to select the optimal reliable node from the reliable area, the power model is used to determine its remaining battery power, and its power ratio is calculated to select the best reliable node.

Let F be battery full charge of the portable communication device of node. At time t, the remaining power of node i is as follows:

$$W_i^{rem}(t) = W_i^{rem}(t-1) - N * W_i^{tr}(t-1,t) - M * W_i^{re}(t-1,t) - W_i^{\text{int}}(t-1,t). \quad (1)$$

The related parameter of the formula is shown in Table 1.

At $t=0$, $W_i^{rem}(t) = F$. It is assumed that the remaining power of a battery lies in two ranges based on power ratio [8].

$$Power\ ratio = \frac{W_i^{rem}(t)}{F}. \quad (2)$$

Then,

$$W_i^{rem}(t) = \begin{cases} low\ \ range, & 0 < Power\ \ ratio < 0.3 \\ high\ range, & 0.3 \le Power\ \ ratio \le 1 \end{cases}. \quad (3)$$

Through the above judgment, when the remaining power of node i is in the high range, it is set as a reliable node; otherwise, it is not.

Table 1 The related parameter of the formula

$W_i^{rem}(t)$	remaining battery power of node *i* at time *t*
$W_i^{rem}(t-1)$	remaining battery power of node *i* at time *t*-1
$W_i^{tr}(t-1,t)$	the power required to transmit a data packet from *t*-1to*t*
$W_i^{re}(t-1,t)$	the power required to receive a data packet from *t*-1to*t*
$W_i^{\text{int}}(t-1,t)$	power required to perform node's internal operations for the duration *t*-1 to *t*
N	the number of transmitting data packet
M	the number of receiving data packet

Mobility model. The initial position of node *i* and *j* is (X_i, Y_i) and (X_j, Y_j) respectively, at the same time, their speed constantly changes, and the nodes are moving in a particular direction. Assumed that the node moves in the X-axis positive direction, the angle of node *i* and *j* is $\theta 1$ and $\theta 2$ respectively. At time *t*, the moved distance of node *i* and *j* is $d1$ and $d2$, and their new position is (X_i', Y_i') and (X_j', Y_j'), is shown in Fig.1[8].

$$X_i' = X_i + d1Cos\theta_1, \quad Y_i' = Y_i + d1Sin\theta_1, \quad X_j' = X_j + d2Cos\theta_2, \quad Y_j' = Y_j + d2Sin\theta_2. \tag{4}$$

In practice, it is not possible for nodes to move in a constant velocity. So average speed is presented for distance calculation. Let V_i , V_j as the average speed of node *i* and *j*, then $d1 = V_i \times t$, $d2 = V_j \times t$.

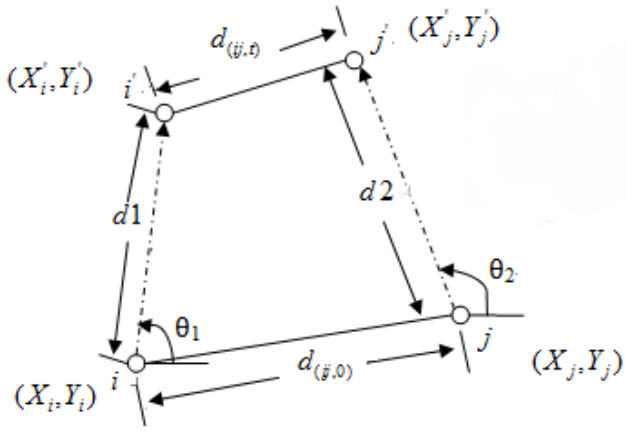

Fig.1 A pair of nodes: before and after mobility

Expiration time of full path. Aussmed that nodes' communication radius is *R*, the link expiration time is $LET(i,j)$, and the path expiration time is *PET*.

$$LET(i,j) = \frac{-(mn+pq) + \sqrt{(m^2+p^2)R^2 + (mq-np)^2}}{m^2+p^2}. \tag{5}$$

Where $m = V_i Cos\theta_1 - V_j Cos\theta_2$, $n = X_i - X_j$, $p = V_i Sin\theta_1 - V_j Sin\theta_2$, $q = Y_i - Y_j$.

Since the entire path is composed of many links, the path expiration time is determined by the following equation.

$$PET = \min_{i\in(1,2,\ldots,k)}(LET(i,j)). \tag{6}$$

Encounter probability model. The optimal path of two adjacent reliable nodes is computed by encountering frequency of nodes. Since the nodes are independent each other, the maximum delivery rate of data packet can be calculated. Reliable nodes split paths into the number of disjoint sub-paths. R_i^* represents the optimal path in the ith sub-path.

$$R_i^* = \max\left\{\frac{\sum_{l\in R_i} f(t)}{nR_i} \middle| R_i \in R_{s,d}\right\}.$$

$$s.t. \quad R_i^* = \{s = A_i, a_i, a_{i+1}, A_{i+1} = d\}. \tag{7}$$

Where the i presents the ith optimal sub- path, A presents reliable nodes, a presents intermediate nodes, $f(t)$ is frequency of the received data packets which equals to node encounter probability. $f(t)$ is as follows:

$$f(t) = m/M . \tag{8}$$

Assuming node is randomly mobile and mutually independent. Maximum probability of data packet delivery from source node S to destination node D is as follows:

$$P_{\max} = \prod_{i=1}^{n} R_i^* . \tag{9}$$

Analysis and discussion

Expected path lifetime of RNMR. Path lifetime can be judged by the path stability and its Cumulative Distribution Function (CDF), and it can be obtained by mathematical derivation. Between the source node S and the destination node D, there are three paths: a primary path and two corresponding backup paths. The three paths are composed of link-disjointness multipath, the common nodes in the links are reliable nodes, and the backup path length between two adjacent reliable nodes is 3 hops. The primary path is the shortest distance path connected by reliable nodes and intermediate nodes. Reliable nodes will split the whole path into m-1 sub-paths, the ith path is expressed as the L_i (i =1, 2... m-1) and has the lifetime X_{L_i}. L_i has two backup paths represented as $BP_{(i,1)}$ and $BP_{(i,2)}$, respectively. The corresponding link of $BP_{(i,1)}$ is $BP^1_{(i,2)}$, $BP^2_{(i,2)}$ and $BP^3_{(i,2)}$ which have lifetime of $X^1_{(BP_i,2)}$, $X^2_{(BP_i,2)}$ and $X^3_{(BP_i,2)}$. The corresponding link of $BP_{(i,2)}$ is $BP^1_{(i,2)}$, $BP^2_{(i,2)}$ and $BP^3_{(i,2)}$ which have lifetime of $X^1_{(BP_i,2)}$, $X^2_{(BP_i,2)}$ and $X^3_{(BP_i,2)}$, the lifetime of backup path is $X_{(BP_i,1)}$ and $X_{(BP_i,2)}$.

$$X_{(BP_i,1)} = \min(X^1_{(BP_i,1)},\ X^2_{(BP_i,1)},\ X^3_{(BP_i,1)}). \tag{10}$$

$$X_{(BP_i,2)} = \min(X^1_{(BP_i,2)},\ X^2_{(BP_i,2)},\ X^3_{(BP_i,2)}). \tag{11}$$

The two backup paths are represented as $LBR_{(i,1)}$ and $LBR_{(i,2)}$ which has the lifetime of $X_{(LBP_i,1)}$ and $X_{(LBP_i,2)}$ respectively. When the primary path connection fails, it selects an optimal path of two backup paths for message transmission. X_{LBR_i} is the longest lifetime of backup paths.

$$X_{LBR_i} = \max(X_{L_i}, X_{(BP_i,1)}, X_{(BP_i,2)}). \tag{12}$$

The lifetime T of the path from S to D is expressed as follows:

$$T = \min(\max(X_{L_1}, X_{(BP_1,1)}, X_{(BP_1,2)}), \max(X_{L_2}, X_{(BP_2,1)}, X_{(BP_2,2)}), ..., \max(X_{L_{m-1}}, X_{(BP_{m-1},1)}, X_{(BP_{m-1},2)})). \tag{13}$$

The CDF of path lifetime T is as follows:

$$\begin{aligned} F_T(t) = P[T \le t] &= P[\min(\max(X_{L_1}, X_{(BP_1,1)}, X_{(BP_1,2)}), \max(X_{L_2}, X_{(BP_2,1)}, X_{(BP_2,2)}), ..., \\ &\qquad \max(X_{L_{m-1}}, X_{(BP_{m-1},1)}, X_{(BP_{m-1},2)})) \le t] \\ &= P[\min(X_{LBR_1}, X_{LBP_2}, ..., X_{LBP_{m-1}}) \le t] \\ &= 1 - \prod_{i=1}^{m-1} (1 - P[X_{LBR_i} \le t]) \\ &= 1 - \prod_{i=1}^{m-1} (1 - F_{X_{LBR_i}}(t)). \end{aligned} \tag{14}$$

Assuming X_{L_i} (i=1, 2, ... , m-1) is independent and identically is distributed random variables. Its probability density function is approximately equal to exponential distribution. The probability density function of X_{LBR_i} is $f_{X_{LBR_i}}(t) = \lambda_i e^{-\lambda_i t}$ [9], where $\lambda_i = (m-1)/l$, l is the average lifetime of the link. CDF of X_{L_i} and X_{LBR_i} are as follows:

$$F_{X_{L_i}}(t)=1-e^{-\frac{1}{l}t},\quad F_{X_{(BP_i^1,1)}}(t)=1-e^{-\frac{3}{l}t},\quad F_{X_{(BP_i^1,2)}}(t)=1-e^{-\frac{3}{l}t},\quad F_{X_{LBP_i}}(t)=(1-e^{-\frac{1}{l}t})(1-e^{-\frac{3}{l}t})^2. \tag{15}$$

We obtain the CDF of T as follows:

$$\begin{aligned} F_T(t) &= 1-[1-F_{X_{L_i}}(t)F_{X_{(BP_i^1,1)}}(t)F_{X_{(BP_i^1,2)}}(t)]^{m-1} \\ &= 1-[1-F_{X_{LBR_i}}(t)]^{m-1} \\ &= 1-[1-(1-e^{-\frac{1}{l}t})(1-e^{-\frac{3}{l}t})^2]^{m-1} \\ &= 1-(e^{-\frac{1}{l}t}+2e^{-\frac{3}{l}t}-2e^{-\frac{4}{l}t}-e^{-\frac{6}{l}t}+e^{-\frac{7}{l}t})^{m-1}. \end{aligned} \tag{16}$$

Path lifetime comparison of several routing protocols: RNMR, GBR-WB and BSR. In order to study the path lifetime of RNMR, the paper conducts the comparison with GBR-WB and representative multipath routing protocol BSR. GBR-WB is a GBR routing protocol without local backup path. Its lifetime is approximately equal to l/h, where l is the lifetime of average link, h is the path length [10].

BSR [11] is a multipath routing protocol and may have common nodes or links among the paths. It obtains the similarity cost function by similarity of links and nodes and construct backup path.

CDF of BSR lifetime is as follows [9]:

$$F_T(t)=1-e^{-kt}\prod_{j=1}^{w}(e^{-h_jt}+e^{-h_j't}-e^{-h_jt-h_j't}). \tag{17}$$

Where k represents the number of the same link between the primary path and the backup path, w represents the number of disjoint sub-paths, $h_j$and h_j' (j = 1, 2, ⋯, w) indicate the corresponding length of disjoint paths.

In order to verify the performance of RNMR routing protocol, it will compare with GBR-WB and BSR. the setting of parameters is shown in Table 2.

Table2 Setting of parameters for RNMR, GBR-WB and BSR

l	1s
k	0
h=m-1	2,3,4,5,6,7,8
h_j	2
h_j’	3

Acoording to the theory analysis, when the primary path length of RNMR, GBR-WB and BSR changes, the corresponding path lifetime can be obtained.

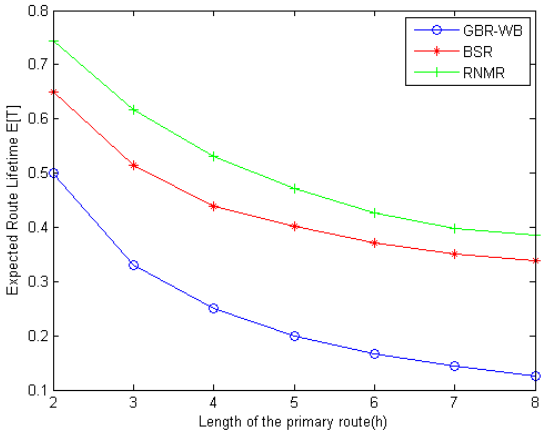

Fig.2 Expected route lifetime of different primary route length

Fig. 2 shows that, with the increase of primary route length, the route lifetime is reduced. There are two main reasons for the phenomenon: One reseaon is that with the increase of path length , the stability of the path is reduced; the other reseaon is that with the increase of the primary path length,

the length of the corresponding backup path will also increase. Seen from the figure, it is obvious that the lifetime expectancy of RNMR routing protocol is significantly higher than GBR-WB and BSR.

Conclusions

In opportunistic networks, nodes move which make the dynamic topology change constantly and the path be frequently interrupted. Therefore, it cannot guarantee successful transmission of message from the source to destination. This paper presents RNMR routing protocol to improve the path stability of the opportunistic networks. RNMR routing protocol selects the best reliable node by power model in reliable region. Through the introduction of reliable nodes, the primary path is divided into several disjoint sub-paths. The backup paths of each sub-path exist independently. This improves the lifetime of the entire route as well as reduces packet loss rate and delay so that QoS of network has been obviously improved. Primary path is the shortest distance path chosen between reliable nodes and intermediate nodes, while the backup paths are two selected best backup paths calculated by the nodes' encounter probability model. When a link of the primary path fails, the upstream node of the link could continue to find path through backup paths.

By comparing RNMR with GBR-WB and BSR, it turns out that RNMR routing protocol has a longer path lifetime, which further reduces the packet loss rate and delay, thus makes the QoS of opportunistic networks be guaranteed.

Keywords: Privilege Separation, Web Workers

Abstract. In this paper, we propose to use Web Workers [1], isolated parallel threads in current browser working in the background, to enforce privilege separation in chrome extensions. Our tests show that our design is applicable to most chrome extensions (those not using the jquery library) and achieves a reduction in TCB up to 77 percent for our examples. Our implementation shows that our design is efficient enough to enforce privilege separation in chrome extensions and not needs to modify the browser or learn new high-level languages.

Introduction

With Web applications and browser extensions becoming more and more popular, the web vulnerabilities are still pervasive [2]. The Web applications that own the elevated privileges are the main target of attackers.

The Google Chrome Extension platform has recognized the necessity to enforce privilege separations in the chrome extensions. The Google Chrome Extension platform divides a chrome extension into two components: the core extension that runs in an isolated sandbox and content scripts that are in charge of interacting with the browser [4]. The permission mechanism enforces restrictions on the privileges the extension requires [7]. However, this design that needs to modify the browser and its permission mechanism is not sufficient enough to enforce privilege separation because of its coarse grained policies.

Recently, the paper [3] proposes a language-based approach to isolate an application by assigning every component a minimum of privileges of a Web application, each of which forms an isolated domain. But, in this approach, it is necessary for developers to learn a new high-level language that is time consuming and can't maintain completed compatibility with legacy code.

In 2012, iframes are proposed to enforce privilege separation in Web applications. But it has a shortcoming that the script code in an iframe may impact the main page's liveness, if the script code consumes the resources of the browser or goes into a dead loop [6].

In this paper, we proposed to use Web Workers to enforce privilege separation in Chrome extensions. Web Workers provide completely isolated JavaScript environment and work in the background, which can't impact the main page's liveness. In our system, we create a common privileged master and a few unprivileged workers. How many components a chrome extension can be divided is decided by the number of the extension pages, e.g., we divide an extension owning background.html, popup.html and options.html into three components. We just put all the functional JS files from an extension page into an unprivileged Web Worker and other HTML and CSS files still execute in the extension page. The workers communicate with the master with postMessage [6]. The master interposes on all the privileged calls from workers by enforcing a fine-grained policy code that is application-specific and can be modified freely by developers.

We show that our proposal is practical for most existing chrome extensions. We retrofit two Google Chrome extensions to use our design. Its overhead for memory consumption is a little high, but the absolute costs are tolerable (no human perceivable latency). In our examples, the trusted

computing base (TCB) [8] reduces by up to 77 percent and no more than 18 lines of code need to change. And, there is no need for developers to learn new languages.

There is a limitation to use our design. Since Web Workers can't access the DOM, the library jquery will not work in them. As a result, our design is only applicable to these chrome extensions that not using jquery.

Design

In this section, we describe our privilege separation architecture for chrome extensions.

In our design, an extension has a common privileged master and an arbitrary number of unprivileged Web Workers [6]. The privileged master is loaded in every extension page before the extension is packaged. Each unprivileged Web Worker is created by the privileged master in each extension page and all JS files from an extension page execute in its own Web Worker. Since jquery library is invalid in a worker, our design is only applicable to those chrome extensions without using jquery. Figure 1 shows our proposed model for privilege separation.

Master. The master mediates all the privileged calls from the unprivileged Web Workers. The privileged master has four components:

(1) Startup Code. After the extension is loaded, the startup code begins to create a Web Worker and imports all the JS files hosted in the extension page into the worker.

(2) Master Shim. When the script code in a worker makes privileged calls to the privileged master in the extension page, the master shim is in charge of all the privileged calls on behalf of the workers and returns the required results to the corresponding workers.

(3) Policy Code. The policy code specifies what kinds of privileged operations the worker code can ask the master to perform. It is application-specific. The developers can add additional essential restrictions on these extensions or modify some privileges.

(4) Proxy. Since the Web Workers do not have access to DOM, we have to virtualize the DOM （VDOM）[6]. The proxy is in charge of disposing the DOM modification messages from workers.

Workers. Our system moves all functional JavaScript files from different components of an extension to Web Workers. Each worker consists of three components:

(1) JavaScript Code. JavaScript code means the JavaScript files that render operations from the extension page, e.g., popup.js and other JavaScript libraries the page needs.

(2) Worker Shim. The worker shim consists of a wrapper module. It wraps all the privileged functions. When a call is invoked, its corresponding wrapped function marshals the function as a message and posts this message to the master. On receiving respond from the master, the worker shim also deals with the execution of the callback with the results to complete the original call.

(3) Monitor. Since workers have no access to the real DOM, the monitor is in charge of 1) exporting to the Web Worker a Virtual DOM (VDOM) [6], 2) listening to the VDOM modifications, 3) applying the modification events to the master. The VDOM can be implemented by *Jsdom* [9], a JavaScript implementation of the DOM. Besides, we also use the libraries *underscore* and *RequireJS* to complement the JavaScript functionality. The VDOM contains subtrees of the real DOM (the extension's JavaScript code decides which subtrees are used).

Implementation

To integrate our design into a chrome extension, before an extension is packaged, the developer needs to include the master code as a JavaScript file inside every extension pages. When the packaged extension loaded, the startup code in every page creates an unprivileged Web Worker respectively and executes the extension script code in it.

In this section, we focus on the procedure of implementing a privileged call and DOM modification.

(1) Implementing a privileged call. When a privileged API (e.g., chrome.tabs.getSelected) is called, its wrapped function begins to executes, which asks the master to perform the correct function by 1) marshaling the privileged function name and all its arguments as a message, 2) saving the privileged function's callback in

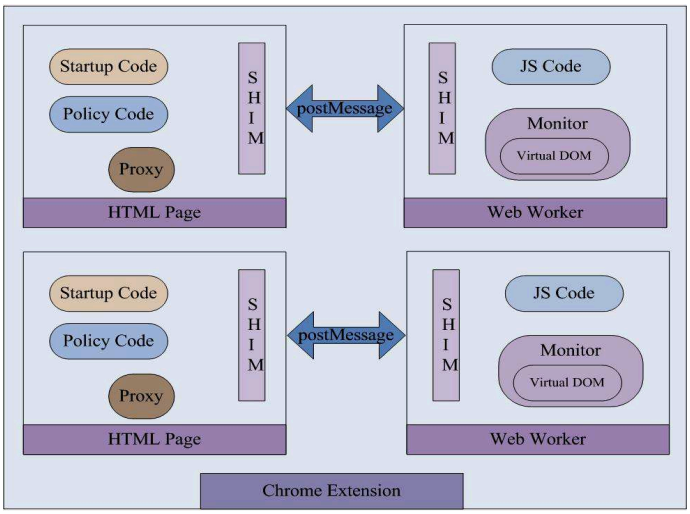

Figure 1: High-level of our architecture

an array, 3) sending the messages to the master, 4) waiting for respond from the master, 5) executing the saved callback with the parameters from the master. Listing 1 is the wrapped function for the chrome.tabs.getSelected.

On receiving a message from a Web Worker, the master shim 1) demarshals the message from the worker, 2) checks with the policy code to see if the call is allowed, 3) executes the correct function if allowed, 4) marshals the results as a message, 5) sends the message back to the worker. Listing 2 shows the master shim for the chrome.tabs.getSelected.

(2) Implementing a DOM modification. When the VDOM is modified, the monitor 1) serializes the events, 2) marshals it as a message, 3) sends the message to the master using postMessage.

Upon receiving this message, the proxy 1) demarshals the message, 2) deserializes the modification event, 3) applies the modification event to the real DOM.

Examples

We apply our design to two chrome extensions to demonstrate that our architecture is efficient enough in privilege separation.

In the two examples we measure (a) the reduction in TCB after using our architecture, (b) the amount of code need to be changed in order to retrofit the application, and (c) performance overheads (load latency, communication time, the interposition time by policies, and memory consumption). Table 1 lists our examples and summarizes our results.

TabJump. We apply our design to a chrome extension called TabJump, which can help a user to easily access most used tabs, associated tabs, and closed tabs, and allow a user to lock the current tab in case of accidentally clicking the close button. This extension has two components: background.html and popup.html. The functionality of background.html is to get tabs information, consisting recently closed tabs, related tabs, and frequently used tabs, then send these tabs to popup.html; when a user click the TabJump button, popup.html opens, which shows all these tabs' link and provide the lock feature.

(1) Unbundling and Example Policy: In the original version of TabJump, popup.html receives the tabs information from background.html and allows users to open, update, or lock these tabs, but runs with full privileges of the extension. Under our design, the popup.js code runs within an unprivileged worker and the policy only gives the popup.js access to the sendMessage API to send and receive the

tabs information from the background page as well as only tabs.create, tabs.update, tabs.getSelected and tabs.getAllInWindow chrome APIs.

PanicButton. PanicButton is a chrome extension that can be used to hide all tabs in the browser just clicking the hide button and restore them by another click. This extension has three components:

```
chrome.tabs.getSelected=function(windowId,callback){
                    var callbackctr = -1;
                    if(typeof callback !== 'undefined'){
                            callbackctr = callbackID++;
                            cached_callbacks[callbackctr] = callback;
                    }
                    var temp = {"type":"chrome.tabs.getSelected",
                                "callbackid":callbackctr,
                                "windowId":windowId};
                    postMessage(temp);
                    };
```

Listing 1: Wrapped function for chrome.tabs.getSelected

```
var msg=event.data;
  if(!policy.allowcall(msg)){return;}
    if(msg.type===" chrome.tabs.getSelected" )
      {
        chrome.tabs.getSelected(msg.windowId,function(tab){
            postMessage({ "type" :" cb_chrome.tabs.getSelected" ,
                          "callbackid" :msg.callbackid,
                          "tab" :tab});
        });
      }
```

Listing 2: Master shim for chrome.tabs.getSelected

background.html, popup.html and options.html. The functionality of background.html is to hide or restore all tabs; a user also can set a shortcut for this button and set a password to manage these hidden tabs in options.html. When a password is set, a user must enter the password in the popup page to restore these hidden tabs.

(1) Unbundling and Example Policy: This extension uses options.html to set a shortcut for the hide button and enter a password in the popup.html to manage the hidden tabs. But these two pages have full privileges of this extension. In our architecture, popup.js and options.js execute in different unprivileged Web Workers, the policy only gives the popup page the privilege to call sendMessage API and the options page the privileges to call chrome.tabs.create and sendMessage APIs.

Evaluation

Our approach has four possible overheads: 1) latency of loading Web Workers; 2) the overhead caused by the parent's mediation on privileged APIs; 3) the overhead on each call crossing the sandbox boundary; 4) the memory consumption of the redesigned extensions. We measure the impact of each below.

Latency. To measure the time overhead, we include two scripts in an extension page's different places, measuring the time elapsed between them. For example, one script is in the page's header and the other at the end of its body to measure the load latency. We perform 10 runs in each extension page, using the JavaScript's Date.now() API to collect the average time . For TabJump, the background load latency is about 319ms, and the VDOM size is 9 KB with 61ms to populate it. The average time on each call crossing the sandbox boundary is about 14ms, and with 13 lines of policy code, the average interposition time is less than 1ms.

As shown in Table 1 and Table 2, without VDOM, our extension runs nearly at a local speed; even with VDOM, we do not observe any user-perceivable increase in latency. The VDOM population time is affected by its size more or less. However, unless the chrome extensions spend most of its time in DOM operations and the VDOM size is not too big, and the total overhead should be tolerable.

Memory. We evaluated the memory overhead by observing the increase in memory consumption caused by creating web workers. We found that with the two extensions, the memory increase is 2.8M and 2.3M respectively. We believe that this level of overhead should be acceptable to enforce privilege separation in chrome extensions. Besides, it's up to a user to close these Web Workers after the chrome extensions exit, since it will not be automatically garbage collected.

Conclusion

We propose a new design that uses Web Workers to partition a web application into an arbitrary number of unprivileged components. Our evaluation shows that we can apply our architecture to most chrome applications and achieve significant reduction in TCB with no more than 18 lines of change for the chrome extensions we studied. However, those extensions that use jquery library do not fit with our model.

Bayesian Inference of Information Theoretic Metrics of Anonymity

Han-Ru Pei[1], Zhi-Jian Wang[1] and Yu Wang[1]

[1]College of Computer and Information, Hohai University, China

Keywords: Bayesian inference, Anonymity, Anonymous Communications, Metrics

Abstract Information theoretic metrics is popular theory to measure anonymity. However the difficulty in getting the probability distribution of subjects hampers its practical usage. In this paper we propose a Bayesian inference method to tackle this problem. Our method makes it possible to compare the anonymity of different anonymous systems. We use this method to analyze Threshold Mix and point out different system parameters which do and do not have influence on anonymity.

Introduction

Metrics of anonymity has long been a hot research area. Metrics of anonymity is the quantitative analysis of the degree of anonymity provided by an anonymous communication system. It's used to evaluate the security of anonymous communication technologies. Information theoretic metrics [1] [2] has been widely acknowledged since its inception. However, there are some obstacles in utilizing this theory, among which is one of its assumptions that attackers can build a probability distribution of all subjects using the system. This distribution is very difficult if not impossible to get in practice. In this paper, we propose a method to systematically solve the problem. We first build a statistical model of anonymous communication being studied. By utilizing Bayesian inference and sampling technology, we then get a sampling probability distribution of subjects which can be applied to information theoretic metrics of anonymity.

The remaining paper is organized as follows: we introduce how to measure anonymity using Bayesian inference in section 2; section 3 is experiments and evaluations where we describe our experiment setup in detail and discuss the results; we conclude in the last section.

Anonymity Metrics using Bayesian Inference

Threat Model. We use Mix [3] to provide anonymous communication service; we only focus on traditional Threshold Mix. The attacker is a Global Passive Adversary (GPA) [4]. The attacker is able to monitor all links and connections during the lifetime of the system, intercept and record the metadata of traffic. The attacker is unable to modify, block and replay recorded traffic.

There are N_{mix} mixes (servers) providing anonymous service and N_{user} users using the system. There is also a GPA monitoring the system. Mix works by storing and forwarding users' messages. Messages are flushed in a batch when a mix received N_{t} messages. Mix obfuscates the messages by some cryptographic operations to ensure the attacker cannot find out the relationship between messages it receives and sends. Mixes can be cascaded to further improve security. When a user starts to use the system, first she chooses a user among the $N_{\text{user-1}}$ users as her communication partner. Then she determines the path length L where $L_{\min} \le L \le L_{\max}$. L mixes are selected randomly next to form a cascade path P. Finally her message is sent through the path to its receiver anonymously.

Bayesian Inference Overview. Let's assume an abstract anonymous communication system C. Its traffic flow is composed of observed data O and a set of unobservable hidden states H. The attacker is interested in H. By applying Bayes' rule, we can compute the probability distribution of H:

$$\Pr(H \mid O, C) = \frac{\Pr(O, H \mid C)}{\Pr(O \mid C)} = \frac{\Pr(O \mid H, C) \times \Pr(H \mid C)}{\sum_H \Pr(O, H \mid C) = Z} \tag{1}$$

In theory, knowing how C – the anonymous communication system – works is all we need to perform analysis by utilizing Bayesian inference technique. In practice however, $\Pr(H \mid O,C)$ is hard to compute directly due to the immense number of possible hidden states H. We have to resort to Markov Chain Monte Carlo (MCMC) methods to approximate $\Pr(H \mid O,C)$.

MH Algorithm Overview. It has been noted before that the aim of the attacker is to find the probability of sender S_x corresponds to receiver R_y given observations O and constraints C. This problem can be transformed to the problem of finding the probability of input corresponds to output of every mix in the system, notated as H. Unfortunately, for complex systems, it is infeasible to enumerate all H . We know $\Pr(H \mid O,C) \propto \Pr(P \mid C)$, so this problem can be transformed again to the problem of finding the probability of any possible path in the system. We use MH algorithm [5] to get path samples. For any sender S_x and any receiver R_y, we approximate:

$$\Pr(S_x \to R_y \mid O,C) = \Pr(H \mid O,C) \propto \Pr(P \mid C) \approx \frac{\sum_{i \in N_{\text{sample}}} \mathrm{I}_{S_x \to R_y}(\text{Sample}_i)}{N_{\text{sample}}} \tag{2}$$

where Sample_i is one separate sample from the sample set. N_{sample} is the sample size. $\mathrm{I}_{S_x \to R_y}$ is an indicator function on whether S_x corresponds to R_y in the sample.

We randomly choose an initial state MH_0. Then we do random walk on the Markov chain until we get a steady state which correctly reflects our target distribution, that is $\Pr(P)$. Two transform functions are defined. T_1 doesn't change current state. Current state will be the candidate state. T_2 randomly exchanges two inner links of a mix. The proposal distribution of MH algorithm depends on the transform functions as well as the probability of choosing which transform function. Clearly, $\Pr(T_1)+\Pr(T_2)=1$. Proposal distribution is defined as follows:

$$\mathrm{Q}(MH' \mid MH_j) = \begin{cases} \Pr(\mathrm{T}_1) & \mathrm{T}_1 \\ \Pr(\mathrm{T}_2) \times \dfrac{1}{|\mathrm{Mix}|} \times \dfrac{1}{N_t} \times \dfrac{1}{N_t - 1} & \mathrm{T}_2 \end{cases} \tag{3}$$

Given current state MH_j, proposal distribution Q and candidate state MH', we determine whether to accept candidate state as the next state:

$$\alpha = \frac{\Pr(MH') \times \mathrm{Q}(MH_j \mid MH')}{\Pr(MH_j \mid \times \mathrm{Q}(MH' \mid MH_j)} \tag{4}$$

If $\alpha \geq 1$, MH' is accepted as the next state; otherwise MH' is accepted as the next state with probability α.

Entropy Anonymity Sampling. For any sent message S_x, let the distribution of N possible corresponding received messages R_y(y=1,2,…,N) be Φ_x, the entropy anonymity of message S_x is:

$$H(\Phi_x) = -\sum_{y=1}^{N} \Pr(S_x \to R_y) \times \log_2 \Pr(S_x \to R_y) \tag{5}$$

It should be emphasized that the distribution from Eq. (2) is only the sampling distribution of Φ_x which is derived from paths data from samples, rather than the actual distribution of Φ_x. There may be paths haven't been sampled that have non-zero probability. We resort to Bayesian inference again to evaluate Φ_x. We model Φ_x as a multinomial distribution of R_y. In Bayesian statistics, Dirichlet distribution is a conjugate prior of multinomial distribution. For a given S_x, we assume the attacker has no prior knowledge about R_y, i.e., the prior distribution of Φ_x is Dirichlet(1,1,…,1). We define an auxiliary function $\mathrm{C}(S_x \to R_y)$ which equals the number of samples in which S_x corresponds R_y. Thus the posterior of Φ_x is:

$$\Phi_x \sim \text{Dirichlet}(\mathrm{C}(S_x \to R_0)+1, \mathrm{C}(S_x \to R_1)+1, ..., \mathrm{C}(S_x \to R_N)+1) \tag{6}$$

We retrieve N_D samples per Eq. (6). For each sample, we compute its sampling entropy anonymity $H(\Phi_x)$ according to Eq. (5). We order N_D $H(\Phi_x)$ in decreasing order and take the bounds the anonymity offered by system as the confidence interval of S_x.

Experiments and Evaluations

Experiment Settings. We use effective anonymity set size [1] as the tool to measure anonymity. Since this metrics doesn't normalize, a busy system is sure to have a higher degree of anonymity than an idle system. In order to eliminate this factor, experiments are being conducted under identical number of messages, which is 50. We conduct three experiments which test the anonymity implications of three different parameters, namely the number of mixes N_{mix}, the threshold N_t and the maximum path length L_{max}. They are summarized in Table 1.

Table 1. Experiment Parameters

	Exp1	Exp2	Exp3
N_{msg}	50	50	50
N_{mix}	**3-8**	5	5
N_t	3	**3-8**	3
L_{max}	3	3	**1-5**

N_{obs}=10 observations of message flow in the system are randomly generated for each experiment. For each observation, we get 500 path samples. For every sent message S_x, we record the number of times received messages in samples R_y (y=1,2,…,N_{msg}) correspond to it as C($S_x \rightarrow R_y$). We generate 1000 samples from the posterior distribution Dirichlet(C($S_x \rightarrow R_y$)+1) (y=1,2,…N_{msg}) of $S_x \rightarrow R_y$. We calculate the entropy anonymity of every sample. We then order the results in decreasing order to find the 95% confidence interval of message S_x. We repeat the above steps for every message in every observation and get N_{msg}*N_{obs} confidence intervals. We average on the upper and lower bound of intervals as the final 95% confidence interval of anonymity the system provides.

Results and Evaluations. Since the number of messages is fixed at 50, its maximum entropy is $\log_2 50 \approx 5.644$. There are three graphs below plotting the 95% confidence interval of entropy anonymity under 3 different parameters. H(min) and H(max) are the upper and lower bound of intervals. We can see from the left part of Fig. 1 that N_{mix} has little impact on the entropy anonymity. For N_{mix}=3 and N_{mix}=8, the entropy only increased from 2.844 to 3.104. In other words, by adding 5 mixes, the effective anonymity set size only increased $2^{3.104} - 2^{2.844} \approx 1.4$.

From the right part of Fig. 1 we can see that N_t has significant impact on the anonymity. For N_t equals 3 and 8 respectively, the entropy increased from 3.061 to 4.106. The effective anonymity set size increased by approximately 8.9. When N_t becomes larger, the mixes have to store more messages before flushing them. Also messages will be delayed for more time. So by increasing N_t, we get better anonymity with the price of worse delay and more storage resources.

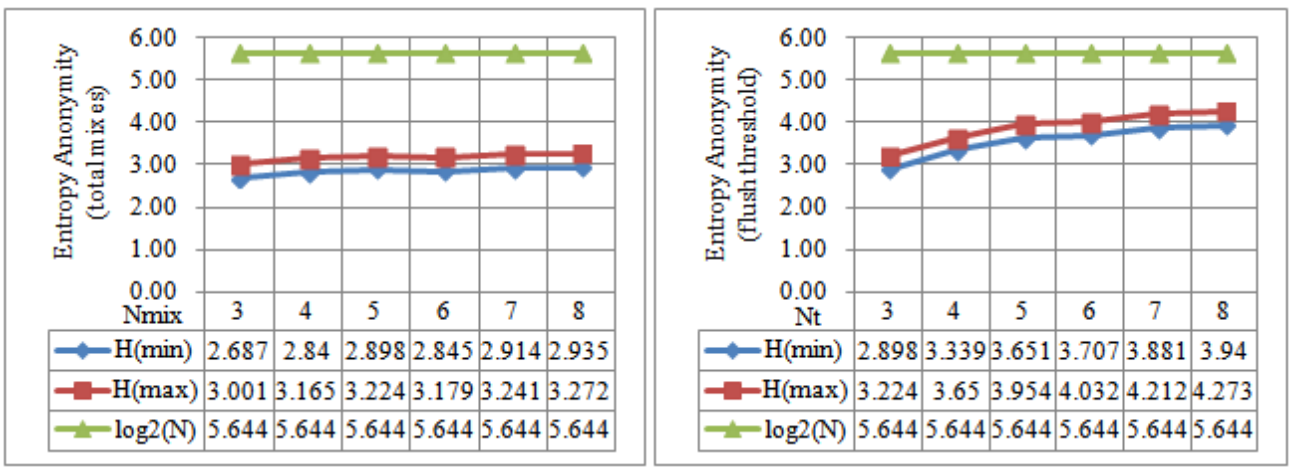

Figure 1. Entropy anonymity under different total number of mixes (left) and different flush threshold (right)

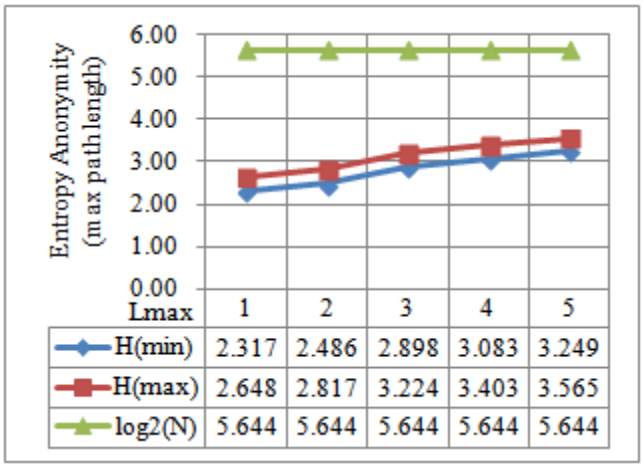

Lmax	1	2	3	4	5
H(min)	2.317	2.486	2.898	3.083	3.249
H(max)	2.648	2.817	3.224	3.403	3.565
log2(N)	5.644	5.644	5.644	5.644	5.644

Figure 2. Entropy anonymity under different path lengths

We find from Fig. 2 that L_{max} also has obvious impact on the anonymity. When L_{max} is 1 and 5 respectively, the entropy increased from 2.482 to 3.407. The effectively anonymity set size increased by approximately 5.0. As with larger N_t, larger L_{max} also increases message delay. Besides, larger L_{max} means more mixes are involved in the activity a message travelling though the system, this adds up to the whole load of the system. So by increasing L_{max}, we have better anonymity with the price of worse delay and more computation resources.

Conclusions

The main contribution of our work is the proposal of a Bayesian framework to measure anonymity. The framework is composed of three steps. First we built a probability statistical model of the anonymous communication system under study. Second we simulated the running of the system, got the path samples of messages in the system, and computed the probability distribution of all senders and receivers in the system. Since what we got is statistical distribution rather than actual distribution, we sampled the results of second step again and finally were able to measure the system under study. We used this method to analyze Threshold Mix. We found that different threshold and different path lengths have significant influence on the anonymity of the system. We also found that contrary to common knowledge, more mixes in the system only has neglectful influence on the anonymity.

Keywords: multitasking; software failure model; high-risk ; military software

Abstract. At present, existing methods are difficult to analyze the Safety of Multitasking and complex timing sequence software. In order to overcome this difficulty, a new analysis method of multiple state transfer and real-time logic analysis method (MSTRT-TPN) is proposed. This method extends the time Petri net analysis rules and proposes the concept of synchronous synthesis and sharing synthesis. It combines temporal logic and state transition, establishes software failure model. Through the model, the possibility of high-risk state of software can be analyzed. The effectiveness of the proposed method is verified through application in three protection device software which is typical safety-critical military software.

Introduction

With the development of weapons intellectualization and information, software has become an indispensable part of tank and armored vehicle equipment, helicopters, artillery and so on. And with the increase of military software function, software data flow and control flow are becoming more complex.

At the same time, the major accidents caused by the failure of the software are becoming more and more. Software security not only seriously affects the weaponry operational effectiveness, but also disastrous consequences, which causes the loss of our personnel casualty and equipment. The key of military software security research has become an urgent problem.

Software safety definition in academia has several different versions. The military standard GJB142-2004 defines software safety "The software has the ability, which does not lead to accidents". It emphasizes two aspects. On the one hand, software safety is the decomposition of the system safety, due to system security. On the other hand, software safety closely associated with the hardware, because software shows failure through hardware. Software alone is not an accident。 Software safety is different from security and software reliability.

Safety analysis methods include the fault tree analysis, *SFMEA* and *Petri* etc.. These methods have certain help for software safety analysis which are single task or a serial task , but there are some difficulties on the analysis of multitasking software safety. This paper puts forward a kind of new analysis method which provides an effective way to solve this problem.

The principle of TIME Petri nets

Petri network is an information flow model of mesh structure, it describes the relationship between conditions and events. The Petri net is composed of five parts :

$\phi = (P, T, I, O, \mu)$, Among them, $P = \{p_1, p_2, ..., p_m\}$ is a finite set position, $T = \{t_1, t_2, ..., t_n\}$ is a finite set of transfer; I: $T \to P^{\infty}$ is the input function by transfer to the location package (from P to T directed arc); O： $T \to P^{\infty}$ is the output function from the transfer to the position package (from T to P directed arc); Mark μ is assigned to a set of tokens in the Petri network, $\mu : P \to \{0, 1, 2, ...\}$ is a function from the position set P to the non negative integer N

A Petri network structure can be used in an equivalent Petri net picture to express. In the Petri network, "O" indicates the position, "1" indicates transfer,Twhe position and transfer connect through directed arc. Token is represented by "• ". The mark is used to represent the distribution state of

the token. By the ignition of the transfer and position change of the token, Petri nets describe the system dynamic behavior.
It finds out the conflicting state and analyzes the causes according to the operating results.

MSTRT-TPN MODEL

A. The definition of single task time Petri nets

Definition 1.1: If $\varphi=(P,T,I,O,\mu)$ is a Petri net (PN), $P=\{p_1,p_2,...,p_m\}$, $p_i=(b_{i1},b_{i2},...,b_{ik})$, Among them $b_{ij}=0,1(j=1,2,...,k;\ i=1,2,....m)$ .When Transfer $t_i\in T$,Transfer conditions is as follows.

The input domain :

$$t=(p_{i_1},p_{i_2},...,p_{i_r})=\begin{pmatrix}(b_{i_1}1,b_{i_1}2,..b_{i_1k}),\\(b_{i_2}1,b_{i_2}2,..b_{i_2k}),\\...,\\(b_{i_r}1,b_{i_r}2,..b_{i_rk})\end{pmatrix} \quad (1)$$

The output domain:

$$t=(p_{j_1},p_{j_2},...,p_{j_r})=\begin{pmatrix}(b_{j_1}1,b_{j_1}2,..b_{j_1k}),\\(b_{j_2}1,b_{j_2}2,..b_{j_2k}),\\...,\\(b_{j_s}1,b_{j_s}2,..b_{j_sk})\end{pmatrix} \quad (2)$$

The transfer occurred right (i.e: T in μ initiative under) condition is: all input position of input domain have the same component 1, and the output position in the corresponding component is zero.

After $\mu[t>\mu']$ $\mu'(p_{i_ch})=(c'_{i_c1},c'_{i_c2},...,c'_{i_ck})$ Among them

$$c'_{i_ch}=\begin{cases}0 & c_{i_1c}=c_{i_2e}=...=c_{i_rk}=1\\ c_{i_ch}\end{cases} \quad (3)$$

$h=1,2,...,r$ output domain $\mu'(p_{j_d})=(b'_{j_d1},b'_{j_d2},...,b'_{j_dk})$

$$b'_{j_dh}=\begin{cases}1 & b_{i_1h}=b_{i_2h}=...=b_{i_sh}=0\\ b_{jdh}\end{cases} \quad (4)$$

$d=1,2,...,s\quad h=1,2,...,k$

This Petri net is named one-dimensional Petri Net of single-task (i.e: $MSTRT-PN$) , marked: $\phi_{k(0,1)}=(P,T,I,O,\mu)$

Definition 1.2: $\phi_{k(0,1)}=(P,T,I,O,\mu)$ is MSTRT-PN Net,

$$\Phi_{k(0,1)}=(P,T,I,O,Min,Max,\mu) \quad (5)$$

Then it is named one-dimensional time Petri net of single-task (i.e $MSTRT-TPN$) , $P=\{p_1,p_2,...p_m\}$, $T=\{t_1,t_2,...,t_n\}$, $p_i=(b_{i1},b_{i2},...b_{ik})$ among them, $b_{ij}=0,1(j=1,2,...,k\ \ i=1,2,...,m)$

$t_{i'}=((t^1_{i'1},t^2_{i'1}),(t^1_{i'2},t^2_{i'2}),...,(t^1_{i'k},t^2_{i'k}))\qquad i'=1,2,...,n$

, $(t^1_{i'j'},t^2_{i'j'})=(\mathrm{mint}_{i'j'},\mathrm{maxt}_{i'j'})\quad j'=1,2,...,k\quad i'=1,2,...,n$

Min and Max are respectively the minimum time function and time function.Transfer t_j t can be multiple times ignition.

The prerequisite is the existence of multiple components 1, and output the corresponding component position in the domain of zero

The rule of multiple times ignition:

1, $t_{i'}=((t^1_{i'1},t^2_{i'1}),(t^1_{i'2},t^2_{i'2}),...,(t^1_{i'k},t^2_{i'k}))$

If Each component is active and $\left(t_{i'1}^1, t_{i'1}^2\right) \cap \left(t_{i'2}^1, t_{i'2}^2\right) \cap \ldots \cap \left(t_{i'k}^1, t_{i'k}^2\right) = \phi$

Then ignition carried out according to the numerical size

2, If $\left(t_{i'1}^1, t_{i'1}^2\right) \cap \left(t_{i'2}^1, t_{i'2}^2\right) \cap \ldots \cap \left(t_{i'k}^1, t_{i'k}^2\right) \neq \phi$, Ignition carried out according to the numerical size of $t_{i'1}^2, t_{i'2}^2, \ldots t_{i'k}^2$;

If $t_{i'1}^2, t_{i'2}^2, \ldots t_{i'k}^2$ is equal Ignition carried out according to the numerical size of $t_{i'1}^1, t_{i'2}^1, \ldots t_{i'k}^1$;

3, If $\left(t_{i'1}^1, t_{i'1}^2\right) = \left(t_{i'2}^1, t_{i'2}^2\right) = \ldots = \left(t_{i'k}^1, t_{i'k}^2\right)$, Ignition carried out At the same time。

B. Sharing synthesis of Petri net operation

The synthetic operation is the synthesis of one-dimensional Petri network as a multi-dimensional network Through the method of sharing the synthetic operation or synchronous synthesis operation

There is a public transfer (or position) in subnet that is a prerequisite for synthesis applications. The public transfer (or position) can be one or more.

Definition 3.5 ： if $\phi_i = \left(P_i, T_i, I_i, O_i, \mu_i\right) \quad i = 1,2 \quad P_1 \cap P_2 \neq \phi$, $T_1 \cap T_2 = \phi$, then $\Phi = \left(P_1 \cup P_2, T_1 \cup T_2, I_1 \cup I_2, O_1 \cup O_2, \mu_1 \cup \mu_2\right)$ is named Sharing synthesis net of subnet ϕ_1 and subnet ϕ_2 [4]。marked： $\Phi = \Phi_1 C_P \Phi_2$

Sharing synthesis requires sub network have a common position, network system after synthesis connect the network through mutual position Sharing synthesis of

C.Sharing synthesis of Petri net operation

The synthetic operation is the synthesis of one-dimensional Petri network as a multi-dimensional network Through the method of sharing the synthetic operation or synchronous synthesis operation

There is a public transfer (or position) in subnet that is a prerequisite for synthesis applications. The public transfer (or position) can be one or more.

Definition 3.5 ： if $\phi_i = \left(P_i, T_i, I_i, O_i, \mu_i\right) \quad i = 1,2 \quad P_1 \cap P_2 \neq \phi$, $T_1 \cap T_2 = \phi$, then $\Phi = \left(P_1 \cup P_2, T_1 \cup T_2, I_1 \cup I_2, O_1 \cup O_2, \mu_1 \cup \mu_2\right)$ is named Sharing synthesis net of subnet ϕ_1 and subnet ϕ_2 [4]。marked： $\Phi = \Phi_1 C_P \Phi_2$

Sharing synthesis requires sub network have a common position, network system after synthesis connect the network through mutual position Sharing synthesis of network can be extended to subnet synthesis of more than two, When combined with the public part of the position, new sharing synthesis of net forms。

D. The synchronous synthesis operations of Petri nets

Definition 3.6：if $\phi_i = \left(P_i, T_i, I_i, O_i, \mu_i\right) i = 1,2$ $P_1 \cap P_2 = \phi$, $T_1 \cap T_2 \neq \phi$, then

$\Phi = (P_1 \cup P_2, T_1 \cup T_2, I_1 \cup I_2, O_1 \cup O_2, \mu_1 \cup \mu_2)$ is named synchronous synthesis net of subnet ϕ_1 and subnet ϕ_2 。marked： $\Phi = \Phi_1 C_T \Phi_2$ 。

Because they do not relate to the position synthesis, token set is not changed compared with the atomic。And the network system of synchronous synthesis can maintain some dynamic properties which system shared. For the complex system modeling, which can be divided into several simple subsystems, each subsystem is constructed one-dimensional model separately, then the whole model is obtained by computing the synthesis of Petri nets.

The establishment of MSTRT-TPN Model

MSTRT-TPN model is established as the following step :

1) Creating the system workflow including software system by Analysis system design documentation and user manual,

2)Writing each subsystem software flow chart. According to the system function realization condition to the state transition process, the task is divided into a number of process. Thus the software system is divided into several sub system (each sub system is a relatively independent).

3）Analysising the software flow chart, listing the process state of each subsystem, and then forming a software feature set。Naming each characteristic state set, determine its meaning, symbol name, scope, initial value

4) According to the time conditions and state transition conditions, each subsystem software characteristic state is organic combined, then a one-dimensional Petri network formed. Then extracting the intersection part of the software flow diagram and the system flow chart, as associated with the software interface of the system input or time conditions to the time Petri net, forming a one-dimensional software K_1 (0,1) -TPN. According to this method, the system of time Petri nets is established.

5）Subnet synthesis shared operation and synchronizing operation is carried. P and t of each subnet is merged to form of multidimensional k_n (0,1) –TPN.

6）Comparing with the actual application, checking Rules of modeling TPN model, including consistency, consistency and completeness.

7）According to the meaning of system symbol name, domain, the initial state, the transfer time threshold, recalibrating of the k_n (0,1) -TPN network

8）According to the actual physical background, The system risk is determined. the dangerous state, can be divided into three levels of risk. Dividing of the risk status classification can refer to GJB /Z 102 - 1997 [7]

9）reachability analysis of dangerous state. Given the network position variable and transfer the meaning of T and range table, get the state reachability graph and Petri net operating table by Petri network model, analysis of high, low risk; to pay attention to every high risk condition, the key state method [8] and the critical transfer node sequence analysis of the state in the back, and find out the key state; by analysis of high risk of path [9], the key reasons put forward high risk path

10）Analysis and modification of the problem. Aiming at the problem, put forward the improvement proposal, modify the system Petri net model.

Verification of engineering cases

A. Safety overview of Three protection device software

Protection device is a device for preventing nuclear, biological, chemical weapons, which is mainly used for the overall protection of tanks and armored vehicles. Through the establishment of high air pressure values in the car, it protects the occupant and vehicle parts which are not or less affected by nuclear radiation, biological, chemical weapon damage. It maximizes the occupant and vehicle survivability, avoides the occurrence of accidents. It is a safety critical software.

B. Safety analysis based on MSTRT-TPN

According to the MSTRT-TPN modeling steps, and combined with the protective device software mission profile, as shown in Figure 1 protection device four-dimensional MSTRT-TPN model.

Figure 1，P_{4i}（i=1…22），Subscript 4 represents the four-dimensional variable input, a represents the gas, B represents a nuclear explosion, C represents the radioactive contamination, D represents the fire. Abstract analysis of the protection device software features state of ZT={chemical gas type, concentration, working mode, actuator state}, the largest state in theory for 64 ={4 222 2}. But considering the actual logic system constraints and the characteristic state stultify oneself, can analyze the 48 state actually can not reach, the actual reachable state only 16.

The executive mechanism is the main hazard protection device. Danger is the executing agency error opening or drain opening, resulting in the potential accident. Risk analysis is to analyze the possibility which appear at the same time, alarm and no protection. In terms of software high risk refers to the warning condition and not the protection state of coexistence. Low risk is no warning and protection status coexist. The key state method

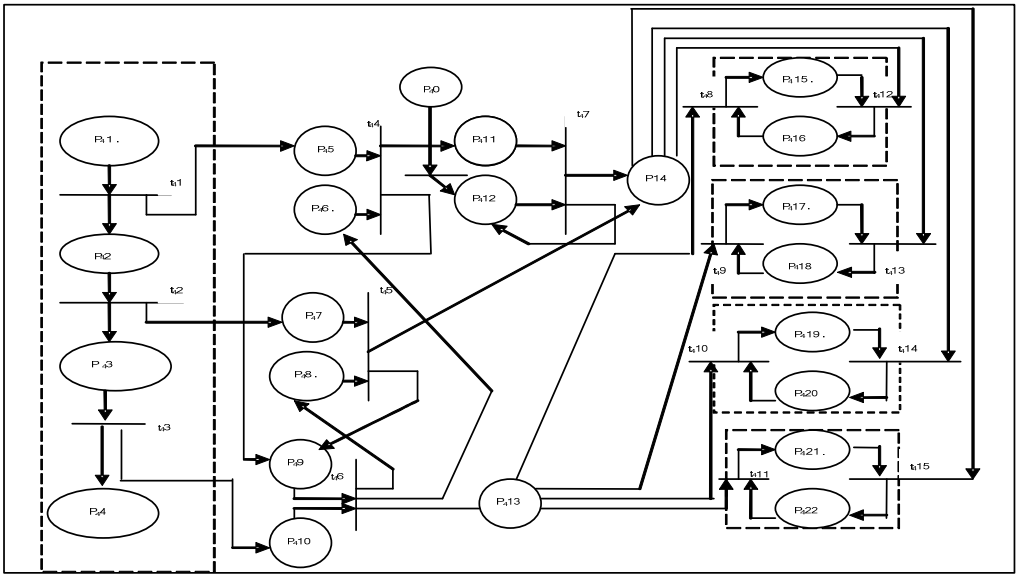

Figure 1 Time Petri net of Three Defense Control System

Using the key state analysis, the reachable state, there are several dangerous:

a. when there are more than 2 kinds of chemical weapons at once, the same execution mechanism is required in the two states which mutually contradictory, it is in a dangerous state.

b. when the alarm, protection mechanism is closed but not in the open state, can lead to casualties.

c. interlock status of P8 and P9 co existing state, it is not logical, not to protect the expected.

d. in manual mode, P411 can not alarm in a specified period of time, while the mechanism is not automatic implementation of protective measures, leading to dangerous state.

e. when the chemical weapons disappeared, protection mechanism not open and remain closed, resulting in low risk status

C. Problem analysis and improvement

In order to limit the high risk, time constraint method is applied to constrained sequence of occurrence, thereby limiting the unsafe state, Petri net model is modified as shown in Figure 2. The following solution is taken:

a, By modifying the software ,four kinds of alarm signal processing priority is added. Software alarmes according to the priority;

b. On the one hand, modify the code execution time (t44+t47+t412) which is less than T42, on the other hand, modify the Petri network, the requirements of T42 transfer ignition after transfer of t412, t413, t414, t415. This design ensures the safety interlock.

c. Modify the design of the software, to avoid the interlocked together.

d. The default state is set to automatic mode; when in manual mode, increase the timer interrupt in software, when in a specified time range no alarm, automatic alarm protective effect, and prompts the operator.

D. Safety analysis based on other methods

At the same time, other traditional methods of safety analysis also are used to analyze three protect software, Result contrasts are shown in Tab1.

Tab 1 Analysis results comparative table

analysis method	The number of software defect	cost of Time and manpower	Analysis ability of Multitasking and timing sequence
MSTRT-TPN	five	low	strong
Time Petri	four	high	middle
The fault tree	three	middle	poor
FMEA	two	middle	poor

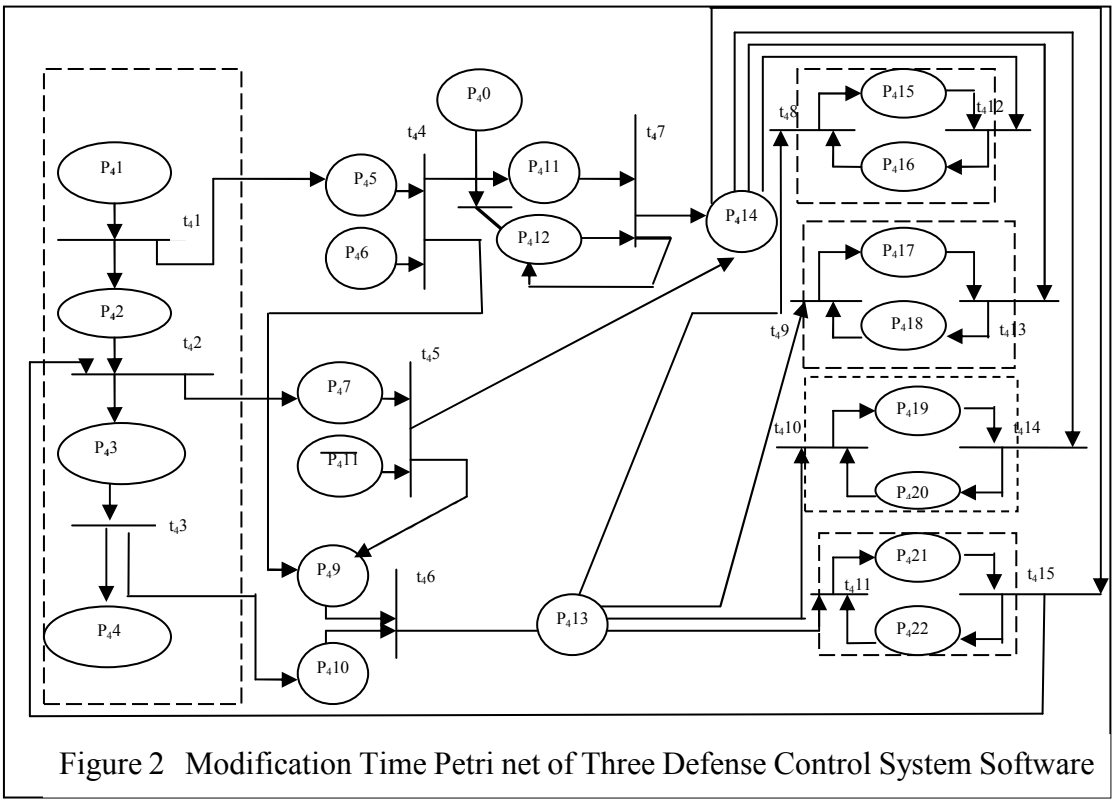

Figure 2 Modification Time Petri net of Three Defense Control System Software

Conclusion

Because of the lack of effective methods of software safety analysis and verification, it is a common practice to rely solely on the latter software testing. It led to pay too high price. We should propose more efficient methods to analyze software security. MSTRT-TPN is a good practice.It makes up the defects of traditional methods and improves the effect of the software security analysis.

Keywords: SDN, Security, Framework, IDS, Firewall

Abstract. With the growing demand for information, it has a strategic importance for the future of sustainable development how to create a safe and robust network system to ensure the security of important information. Intrusion detection technology can proactively react against intrusion behavior and adjust its strategies in time. So it provides an effective means for network security to minimize or avoid loss when network system is attacked. It is an important part of network security system. This article first explains the current framework and the working principle of SDN. Then it explains the existing security threats of current framework. Next intrusion detection system based on SDN is proposed after the introduction of the intrusion detection system. And we made experiments to verify it. Finally we analyze the lack of the structure and propose some improvements.

Introduction

SDN consists of decoupling the control and data planes of a network. It relies on the fact that the simplest function of a switch is to forward packets according to a set of rules. However, the rules followed by the switch to forward packets are managed by a software-based controller.

The logical architecture of SDN is shown in Fig. 1. It consists of application layer, control layer and infrastructure layer.

According to the architecture, we can find that the most important feature of SDN is the use of a centralized approach to forward data. Even though the individual device fails, the entire network still has a very good performance. On the other hand, the openness and centralized management brings an urgent problem, the security problem. Meanwhile, the target of attack is now turned to the control layer and the application layer from physical device.

Traditionally firewall is the first line of defense security. Intrusion Detection System (IDS) makes network security defense more active. Therefore, we apply this technology to the emerging network architecture to resolve some security problems of SDN and make the SDN's architecture safer.

Existing problems of SDN

Major work of SDN:

1. Users define network control and network services network logically through software in application layer so that they can manage routes and network strategies.
2. Control layer receives call from upper layer through application-control interface and is responsible for controlling the forwarding equipment of the underlying intensively.
3. Infrastructure layer receives control message from control layer. It also can process and forward the date packages.

It can be found security needs mainly in the application layer and control layer.

Threats of control layer

1) Sniffer: The attackers forge and modify the signaling after getting network entry point of controller.
2) IP address spoofing: The attackers change the IP address of forged signaling to the controller's IP address through sniffer to defraud switches' trust so that they can destroy the network.

3) DDoS attacks: The attackers send multiple service requests to the controller until the controller refuse to provide services due to overload and all return addresses are forged.
4) Viruses, worms and Trojan attacks: The attackers obtain the control right of controller to execute malicious code through the vulnerabilities existing in the controller.

Threats of application layer

1) Malicious applications: The attackers can implanted worms and spyware applications in the application layer to interfere the normal work process in control plane, including stealing the network information, changing the network configuration, occupying the network resources etc.
2) Applications' safety rules conflict: Application layer need develop security rules to access some security interfaces for providing a wide range of network services. Safety rules conflict occurs between multiple applications because applications become more and more complex. It brings chaos to network services and make management more complicated.

Improvement of SDN framework

Most scholars believe that the current cumulative network security technology is fully capable of SDN security requirements, but we should also consider the following three questions:

1. How to implement traditional network security applications on the SDN architecture.
2. How to define the relevant API of SDN controller to achieve the above functions.
3. Select which network security applications implemented on SDN architecture

Through analysis of these three questions, we get a new framework for SDN.
The improved SDN framework is shown in Fig. 2. The deployment of the overall structure is shown in Fig. 3.

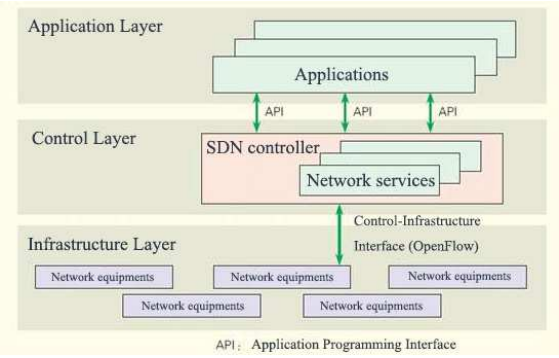

Fig.1 The logical aichitecture of SDN

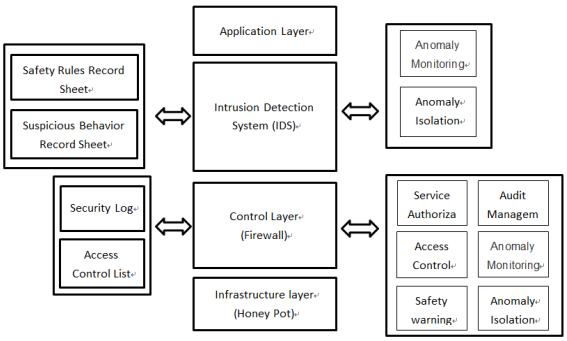

Fig.2 The improved SDN framework

Intrusion Detection System (IDS)

Rules of NIDS based on SDN

The rule is shown as follows: alert tcp 192.12.1.32 :80 -> 192.168.1.12 111
The first item is the conduct of the rule. It defines how the package should be handled when the package matches the rule. There are five default handling: alert, log, pass, activate and dynamic.
The second item is the agreement. The agreements that Snort can analyze are TCP, UDP and ICMP.
The third item is the IP address of the sender. It can be some IP or a range of IP address. It can be presented as 192.12.1.3:192.12.1.15.
The fourth item is the port number of the sender. It is just like the IP. There are three kinds of expression. 12 means the port 12. :80 means the port number can't be greater than 80. Similar, 80: means the port number can't be less than 80. The last one is 80:100, it means the port number must be between 80 and 100.
The fifth item is the direction operator. One-way operation (->) represents the flow direction of the data package. Two-way operation (< >) represents that the system should record and analyze the bi-directional data transferred between the two hosts.
Then they are the IP address and port number of the receiver.

Structure of NIDS based on SDN and functions of each part

It consists of three subsystems:

1) Capture and parsing subsystem
2) detection subsystem
3) log and alarm subsystem

The function of the capture and parsing subsystem is to capture data transferred on the network and parse the package according to different protocols.

Detection subsystem is the core of the IDS's implementation. Accuracy and speed are the important measures of its performance

The former mainly depends on the accuracy of summarizing the intrusion features and the practicality of rules. We should summarize the intrusion features as different eigenvalues of different field. Then we can determine whether the intrusion occurred through the eigenvalues. The latter depends on the organizational structure of the detection subsystem.

The log refers to the ability to promptly record in the simultaneous detection of intrusion. The alarm means the system can timely notice when an intrusion occurs.

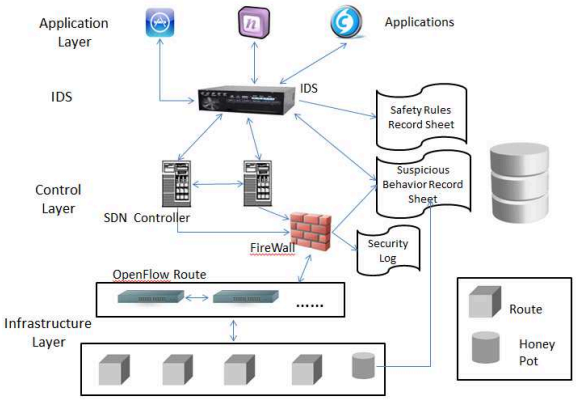

Fig.3 The deployment of the overall structure

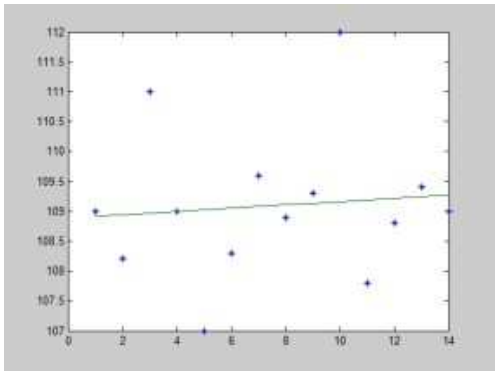

Fig.4 The delayed time's average value of different data packages' number under duplicating process

(Abscissa unit: dozens of data package; Vertical unit: millisecond)

Implementation and verification

Experiment environment

Operating system: Linux Fedora 18
CPU: Intel Core i7-2670QM
Main memory: 4GB
Open source SDN controller: Floodlight
Firewall: Linux Iptables
IDS: Snort

Verification procedures

1) Application layer send PACKAGE IN to Snort
2) Snort executes intrusion detection. If the data package is safe, send it to the controller of Floodlight.
3) Floodlight controller issues instructions to switch based on policy, and redirects PACKAGE IN to the firewall.
4) If the data package is legal, it will be forwarded normally. Otherwise, it will be handled according to the existing rules.

Experiments

We conducted two experiments. The first one is to test the delayed time of 20 times separately in the packet forwarding process and duplicating process and normal transmission process under the new structure. Then take the average of it. The second one is to test the delayed time of different data

packages' number under duplicating process. We also averaged the delayed time. Then we used Matlab to fit curve.

The result of the first experience is shown in Tale 1. The second experience's result is shown in Fig. 4.

Table 1 The average value of delayed time under different operations

Operation performed by the controller	The average value of delayed time (/ms)
Duplicating	1.796
Forwarding	3.656
Normal transmission	0.4526

Considering the results of two experiments, we can conclude that the delayed time won't increase at a high rate of speed with the increasing number of data packages. So when the number is small, the framework doesn't have too much advantage. But the framework may have a good performance when the number of packages is large. Nowadays, people's demand for information is increasing. And big data has become a hot research topic. So our frame can suit the future's network well.

Conclusion

This paper describes how SDN works and the security challenges of SDN. Then it introduces IDS and explains what the frame structure of IDS based on SDN should be and how to deploy. Finally we build environment through open source software and make experiences to verify the framework.

Obviously, there are still some deficiencies. I picked out the following urgent problems as the focus of the next phase of research.

1. IDS can only detect intrusions whose features have been existed in the datebase.
2. If we want to use data mining to obtain the features of intrusions in time. How to design data mining algorithms?
3. The loss of a package will affect the transmission of the file. So what can we do to improve the accuracy of detection.

So, in the next stage of the research, our main goal is to study mining algorithms to make the characteristics obtained through data mining as close to the real situation. And we need design safeguards to ensure proper packet forwarding rate.

Keywords mobile e-commerce; 3D Pipeline; nature of the pipeline; 3D Pipeline's application

Abstract. In recent years, the OTT (Over The Top) was very popular in the communications industry and the mobile Internet industry. The behavior of Internet companies such cross operators, to develop a variety of value-added services and products Internet-based or mobile-Internet-based poses a serious threat to the operators' benefits. In order to change this situation and enhance their competitiveness, it is necessary for the operators to find new interests growth point. So the concept of three-dimensional mobile operators is proposed, and the nature of the pipeline, such as systematicness, spatiality and openness were studied. Finally, the application of 3D pipeline in mobile e-commerce is researched.

Introduction

In recent years, the OTT (Over The Top) concept is very popular in the communications industry and the mobile internet industry. This word comes from basketball and other sports, which means that the ball players pass the ball to another to make it reach the destination back and forth over their heads [1]. Now it refers to the internet companies across the operators to develop value-added services and products based on internet or mobile internet, reflecting the independence of the services in the internet or mobile internet environment and the physical network of operator [2].

Currently the OTT services appear extensively in the field of ICT, for example abroad such as Google, Apple, Skype, Netflix, domestic as Tencent and other companies use the operator's broadband network to develop their own business, such as Apple relying on its smart terminal iPhone, iPad, ITV launch of the iTunes App Store services, voice services provided by Skype, Tencent QQ and WeChat business and so on. The OTT service providers directly provide services to users and charge, enabling operators to become mere 'transmission channel' and cannot obtain benefits which correspond to their heavy investment. It also constitutes a certain threat to the operators' future development [3][4].

Facing the rapid development of OTT services, how to deal with it and achieve transformation has become a key to the operator. 3D pipeline is advanced to avoid mobile operators to become mere "transmission channel" and to seek new growth points of interest, while the realization of restructuring and development.

3D Pipeline

The concept of 3D pipeline. The term of pipeline mostly appears in the industry, and is given its national standard concept in the industry, which is composed of piping components, pipe hangers and other components for transmission, distribution, mixing, separation, discharge, measurement or control fluid flow [5]. Now we have to define the pipeline in the eyes of operators, combined with the operator's industry characteristics, it can be defined as an invisible virtual pipeline for transporting wireless network signals to achieve connection between people.

In the traditional era, the operator's pipeline means voice channels, message pipes and traffic pipes, but with the mobile internet era comes, the traditional pipeline is no longer applicable and will hinder the development of operators, so the operators are in urgent need of transformation. The mobile internet with its characteristics of 'mobilize', 'randomization', 'fragmentation' and 'trust'

becomes a strongly support to the operator to achieve the transformation and increase capacity. Thus, for purpose of fitting the development of mobile e-commerce, the operator proposes a 3D pipeline theory, which is constituted by the connection pipe connecting the enterprise with the operator, channel pipeline providing service for sales and intelligent pipeline managing traffic intelligent.

The nature of 3D pipeline.

1) systematicness

3D pipeline is a system, more precisely, it is an associated pipeline system which consists of three dimensions pipelines. Thus, 3D pipeline has the relationship of the system theory.

The relationship refers to the three dimensions pipelines relating to each other. Only after offering the merchants to come together in the poly platform, it can establish a more generalized cloud sales channel; last the intelligent traffic management is a more commercial value after customers reaching a certain size.

2) spatiality

3D pipeline mainly consists of three dimensions in space,

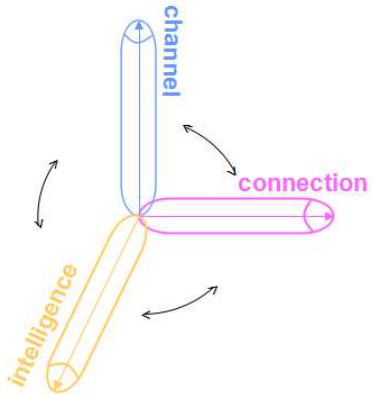

Fig. 1 The spatiality of 3D pipeline

① Connectivity, 3D pipeline connection dimension provides an access to all kinds of businesses, instead of building B2C system by themselves, the merchants can put their goods in the mobile e-commerce platform built by mobile operators, then they are provided display of all kinds of SKU, sales(pre-sale), order, warehouse, logistics (sale) and other after-sales service.

② Cloud Channel, it provides SMS services, ability opening up and distribution in sales channels to merchants. After the Connectivity solves the problem of the merchants to quickly access, the operators help businesses get through customer-oriented services and sale channels by generalization capability.

③ Intelligent, after merchants completing access, settled and sales, the intelligent dimension provides further flow data analysis based on intelligent pipe and decision support capabilities to help businesses better understand customers' behavior and better serve customers. This is a unique characteristic of the operators of mobile e-commerce model.

3) Openness

3D pipeline exists in a certain network environment (such as 2G, 3G, 4G, etc.), so it inevitably exchanges data and information with the other systems in the network. And in the process of exchange, 3D pipeline will experience the dynamic development process which is from junior to senior, from simple to complex and continuously optimized. In order to better realize the self-renewal and self-improvement, 3D pipeline must have a good foreign scalable and open interface.

3D Pipeline's application in mobile e-commerce

The application model of 3D pipeline consists of three parts, shown in figure 2, from the enterprise merchants settled, operator and finally value achievement, this process completely presents the application model of the 3D pipeline.

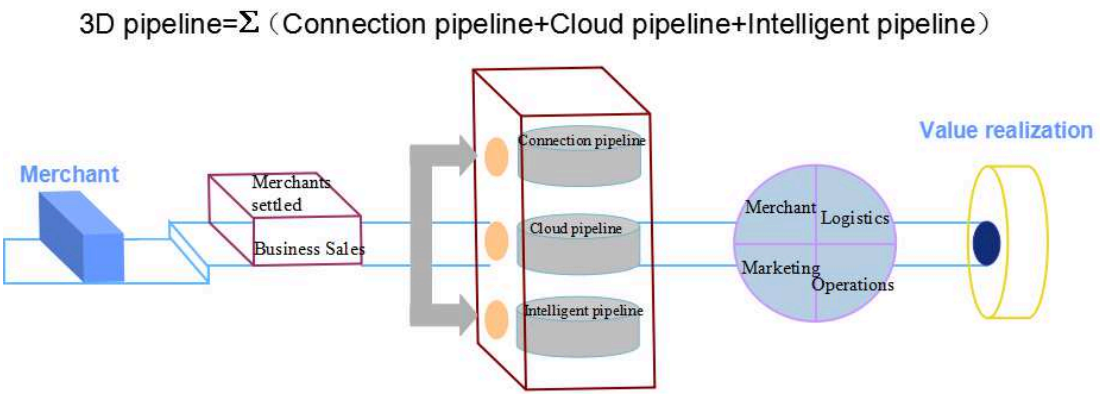

Fig. 2 The application model of 3D pipeline

Connection pipeline - The poly platform

Through Poly platform provided by connection pipeline, it can accomplish merchants settled, product display and sales. In poly platform, 3D pipeline can achieve unified management of businesses and resources, and it also can help the businesses to achieve the management of orders, logistics and payment of the front-end applications.

Cloud pipeline - SMS cloud channel

Cloud platform based on SMS ability opening up can provide such as customer service, marketing and business acceptance and other business operation functions. Cloud channel is dominated by message piping, business templates and other components. The ability to quickly generate data services through business templates, including custom, quizzes, sweepstakes, etc., while providing a unified API, can further support the development and operation of the respective businesses.

Intelligent pipeline - Accurate operation

Accurate operation model based on flow analysis can be said to be the operator characteristics of big data business marketing. And intelligent pipeline can personalize recommendations and provide strong marketing support to merchants through the depth collection of the flow of all kinds of Internet applications, scenario analysis, preferences analysis, and ultimately setting up ability open data by pipeline intelligence.

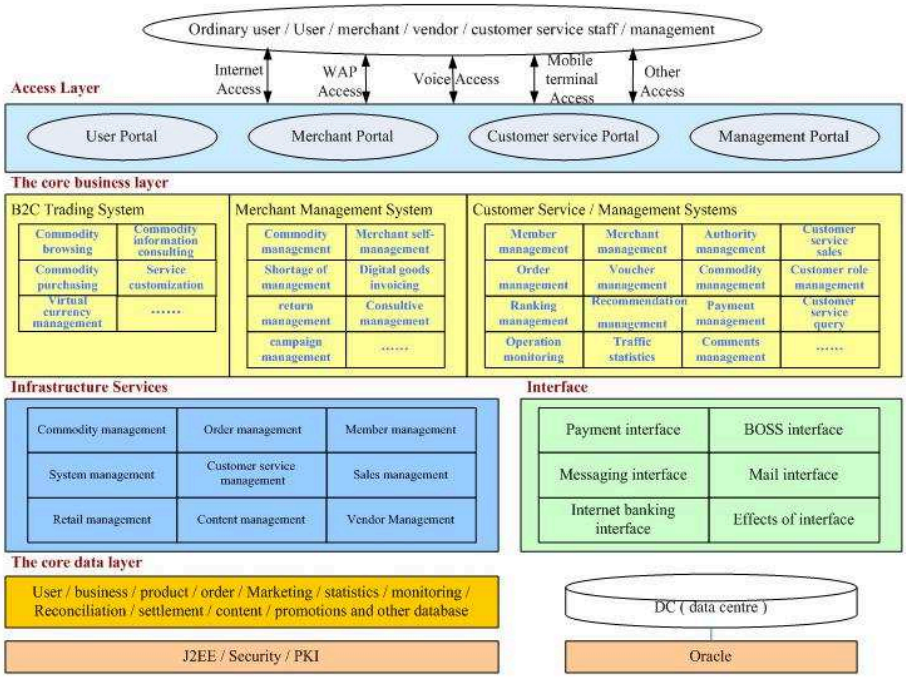

Fig. 3 The mobile e-commerce platform architecture based on 3D pipeline

Summary

With the popularity of smart phones, PDA and other mobile terminals, as well as the development of 3G/4G networks, mobile e-commerce has to show expansive growth in the world, and the

opportunities for people to use mobile devices for business activities will be greatly increased. And the 3D pipeline applied in the mobile e-commerce, will further enrich the mobile e-commerce services, promote market more subtle, rational division to meet the different needs of different people.

Keywords: Authentication Protocol Analysis; MSC2Promela; Structure of Protocol Analysis

Abstract. To discover the existing or possibly existing vulnerability of present authentication protocol, we proposed a structure of authentication protocol analysis, which consist of white box analysis, black box analysis and indicator system as the three main functional components. White box analysis makes use of the transformation from MSCs (Message Sequence Charts) to Promela (Process Meta Language), the input language of the remarkable model checker SPIN; black box analysis is based on the attack platform of authentication protocol analysis; indicator system is decided by deducibility restraint methods. Compared with the UML modeling methods based on Promela, the MSC2Promela methods we figured out on the context have more advantages than its disadvantages. Finally, we proposed a structure of authentication protocol analysis based on the transformation from MSC2Promela, which makes sense to the later work on the area of authentication protocol analysis.

Introduction

With the growing seriousness of the situation of network confrontation, most authentication protocols[1] at present find it difficult to meet the requirement of confidential information security. Many authentication protocols were found vulnerable after versions of publication and years of use. To figure out the existing or possibly existing vulnerability of present authentication protocol, we should focus on authentication protocol analysis. In this paper, we proposed a structure of authentication protocol analysis, which consist of 3 main functional components as follows:

a) white box analysis of known authentication protocol; b) black box analysis of unknown authentication protocol and c) indicator system of authentication protocol under the environment of network confrontation, which main properties and their measurement were reached using the method of deducibility restraint due to different aspects of different authentication protocol.

White box analysis is mainly supported by the transformation from MSCs (Message Sequence Charts) to Promela, the input language of model checker SPIN. By the use of the transformation, user difficulty of modeling authentication protocol by SPIN can be reduced. We proposed an analysis platform of protocol attack, which contains single or multi ways of attack method, to generate black box analysis. With the development of rules of simplifying restraint, indicator system can be decided by the 'solved-form', which was the simple form of authentication protocol simplified by the deducibility restraint. The mentioned structure of authentication protocol is shown in Fig.1.

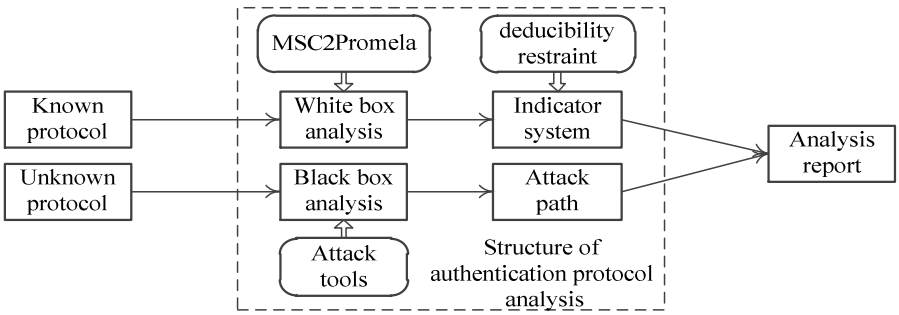

Fig.1 Structure of authentication protocol analysis

Key Technology

Structure of Authentication Protocol Analysis based on MSCs/Promela. Informal analysis of authentication protocol is both difficult and fallible. So it can no longer satisfy the need of security application requirements. Formal analysis, however, is the more rigorous, trusted and standard way to analyze authentication protocol.

MSC[2] is a formal language based on finite communication sequence composition, and plays an important role in the field of visual formalism application of distributed interactive systems. System behaviors, standard test generations and test cases can be depicted using MSCs. Describing in detail the interactions between messages of objects[3] rather than focusing on sending and receiving messages between objects itself is the main specialty of MSCs. MSCs is simple, intuitive, full of readability and easy to learn and practice.

SPIN[4] is a stable and reliable model checker which was widely used in the area of formal analysis, and is one of the most successful open source tools for formal verification of distributed systems. SPIN sets advantages of three kinds of formal analysis methods such as modal logic, model checking and theorem proving methods. The advantages of SPIN, like small memory, original manners of working and high efficiency verification, make it popular in the academic field and engineering field among researchers and engineers. As the input language of SPIN, Promela is a description language that makes it possible to assign behavior of senior system and is the kind of process algebraic language that possesses the function of variable expansion and the structure of programming language. SPIN has been widely applied in the analysis of concurrent systems. However, modeling authentication protocol in Promela, the language which lacks of available tools that act as its auxiliary modeling utilities to translate from other modeling languages, is relatively cumbersome.

To model authentication protocol more clearly and easily for users that have less knowledge about Promela, MSCs can be put forward to associate with model checker SPIN. We may translate authentication protocol model described in formal graphical language MSCs into protocol model in Promela, the input language of SPIN, thereby reducing the difficulty of directly modeling authentication protocol using the Promela, and then use the SPIN model checker to analyze the carried out authentication protocol model. Finally, the analysis results will be displayed respectively in the form of text and graphical MSCs at the same time. The block diagram of authentication protocol analysis based on MSC/Promela was shown in Fig.2, and the two main stages of the analysis process such as modeling-translation and model checking was shown too.

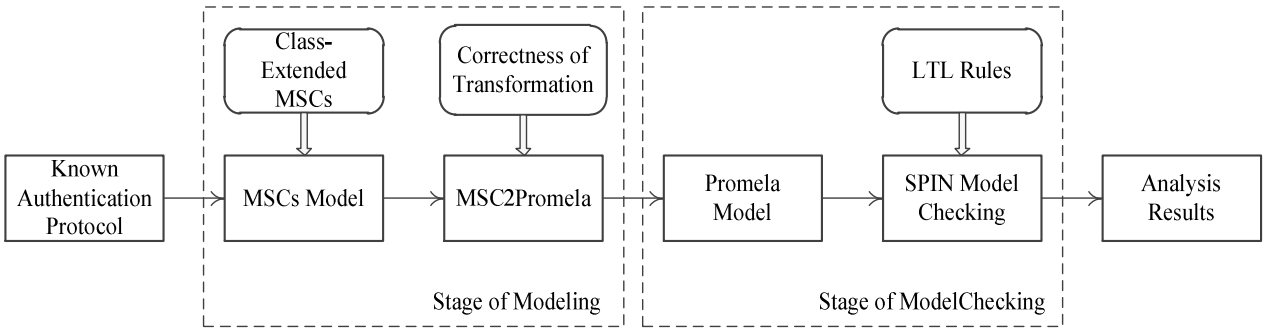

Fig.2 Structure of authentication protocol analysis based on MSCs/Promela

Transformation from MSCs to Promela: MSC2Promela. The main purpose of this transformation is based on the invariance of the semantic of MSCs, during the process of converting MSCs structure to Promela structure. The structure of MSCs is made up of the concurrent object (INIT) that encapsulates process states. Object responds to the received message (MSGS) according to the rules (RULES) defined by the class (PROC), making the corresponding processes. Promela abstracts the concurrent execution of processes, which can communicate through message channels. More than the similar points, the definition of the transformation from MSCs class to Promela process is feasible. MSCs class states can be translated to internal variables of Promela process. Each process instance in Promela has a connected input channel associated to it. All input messages that enter the

process will transmit through the specialized input channel, which can be done by the reference of each MSCs object. The main body of Promela process can be represented as the evaluation cycle applied by process rules. The main compositions of the transformation from MSCs to Promela are shown in Fig.3:

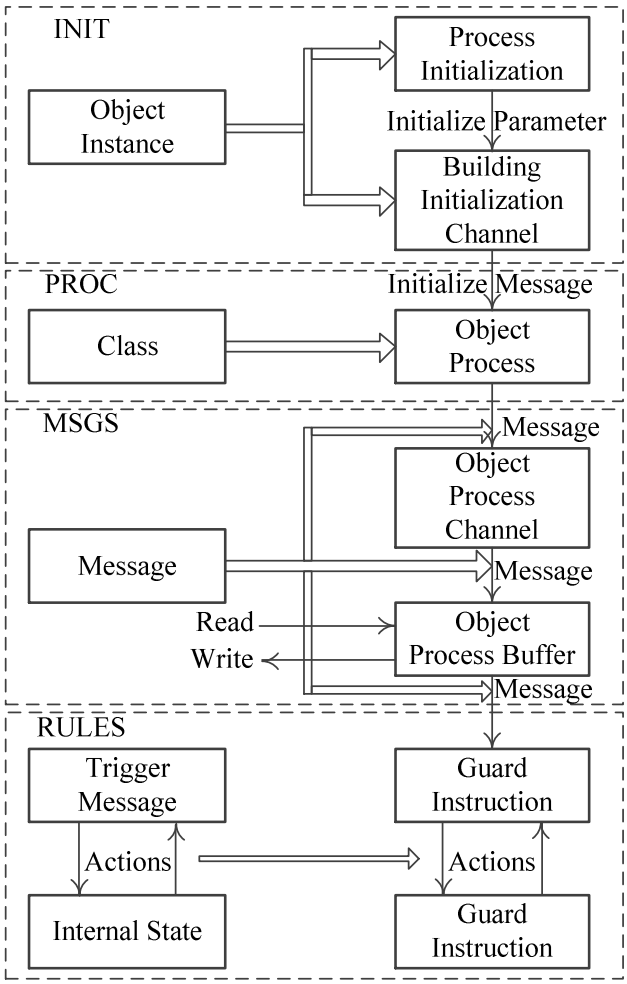

Fig.3 Main compositions of MSCs2Promela

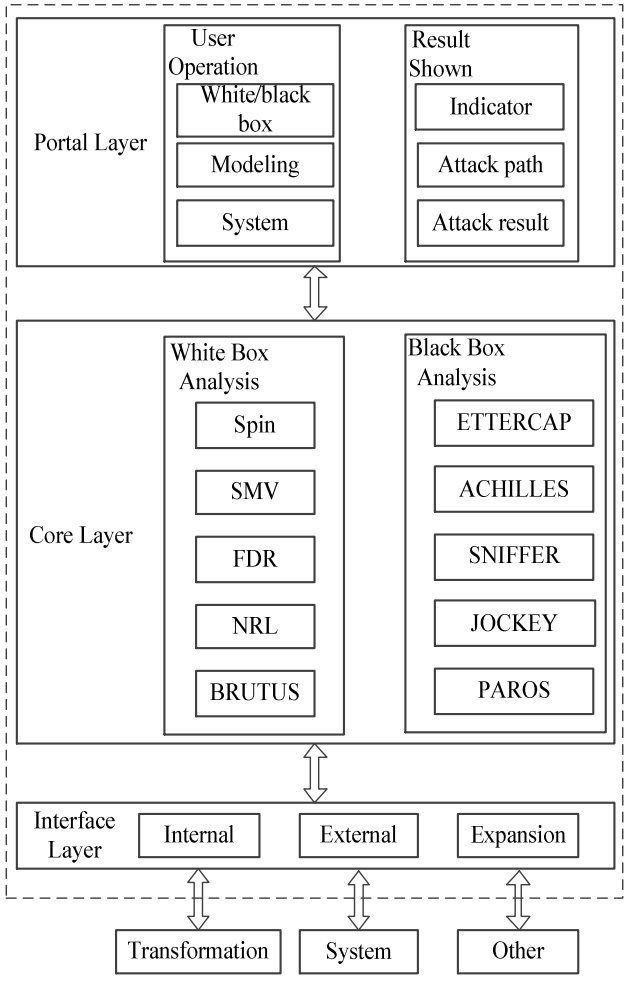

Fig.5 Structure of authentication protocol analysis

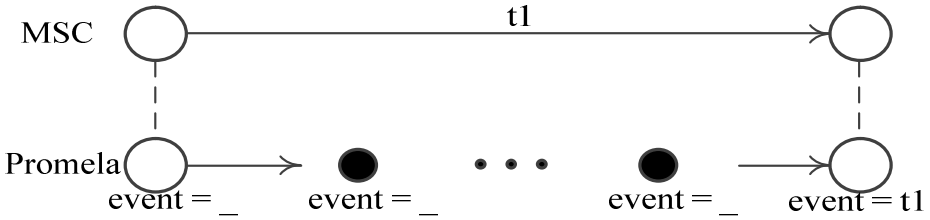

Fig.4 Well-formed states

INIT: The initialization chart of MSCs can be transferred to the INIT process of Promela, and object instances of MSCs can be translated into corresponding creation of input channel and initialization of process in Promela. Messages in initialization chart are transformed to the messages of input channel. Through the above initialization settings, each process can react to the messages from the input channel to make corresponding processes. INIT describes the transformation from the initialization chart of MSCs to the INIT process of Promela. The transformation is implemented by the creation of object process channel. Transferring the relevant parameters of the initialization of object process to the message channel and transferring initialization message to object process through object process channel can respectively activate the object process and its channel.

MSGS: The strategy of transferring messages through message channel in Promela follows FIFO, and there is no concept of message order in MSCs. In the transformation, each process(object process) sends messages to an object process buffer that can execute evaluation and disorderly deal with

messages through input channel (object process channel). Object process buffer has two operations: read (READ) operation and non-deterministic write (WRITE) operations.

RULES: rules of MSCs describe the trigger message (and parameter) and internal state that can be correctly used by rules, and action that can properly apply the rules. Those described by rules of MSCs include the repeat of trigger message, the change of object state, and the generation of new message and object instance. Using guard instructions in Promela can properly correspond to these semantics: evaluations of guard instructions about available messages and current state can be used to detect if rules are correctly applied. The corresponding actions of guard instruction are expressed by the cost of message forwarding and the change of state of process variables as well as the possible generation of new information and processes. The non-deterministic choice of MSCs rules can be mapped into non-deterministic choice of several corresponding guard instruction of Promela.

PROC: MSCs class can be mapped to the static definition of Promela processes. Each MSCs class is mapped to the definition of a process. MSCs object is corresponded to process instance of Promela, namely object process. The body of object process contains the loop of actions such as choosing the message to be executed, evaluating, and applying rules. When object process channel receives a message, the message will be moved to the object process buffer and wait for the process. When the message is selected, an executable rule of the message will be applied.

Correctness proof of MSC2Promela. In order to make sure that MSCs model effectively and correctly transferred to Promela model, we must ensure that the generated sequences of events of the two models are the same, that is, the sequence application of rules generated by MSCs is consistent with the corresponding Promela migration sequence variable. Ensuring the basis of the correctness of model transformation is to ensure that MSCs object state is consistent with Promela process states. This means that at the same time the MSCs object state transferred to Promela process state, the Promela process state can be fully converted to the original state of MSCs object. We call the state that can be transferred in two directions the ‘well-formed’ state.

As shown in Fig.4, the hollow circle represents the ‘well-formed’ state that can be transferred bidirectionally; Solid circle represents the mutual transformation state, that is, in the MSCs people can't find the object state of the corresponding Promela process state. In the operation of protocol, if all protocol steps can be described as a corresponding set of qualified state transition, then we can deduce that the transformation from MSCs model to Promela model is correct.

Contrastive analysis. Modeling method proposed in [5] is aiming at the complementation of formal method and visual UML method, and deal with the transformation UML model to Promela model. Finally they proved the effectiveness of the proposed method. This method slightly lacks advantages in UML modeling, especially the need to generate requirements specifications. Modeling by UML requires the use of class diagram, state diagram and collaboration diagram, respectively. Using this transformation method to model authentication protocol is relatively complicated in general

In this paper, the MSC2Promela modeling method we gave is relatively simple and clear. Authentication protocol can be directly described using class-extended MSCs. At the same time, the accuracy of transformation method of MSC2Promela, on the premise of which MSCs model can be achieved by promela model and the other way around, can be assured. Finally, after authentication protocol modeled by MSC2Promela is analyzed, the result of the analysis of model checker SPIN will be displayed through text and MSCs graphical. But the transformation method of MSC2Promela is only currently applicable for authentication protocol analysis, and the requirement of class extension of MSCs is indispensable, which increases the difficulty of modeling authentication protocol. Comparison results are shown in table 1:

Table 1 Difference between MSC2Promela and Promela-based UML

Modeling Method	Difficulty	Principal	Direction	Result form	Scope
MSC2Promela	Convenient	Correctness	Two-way	Graph/Text	Protocol Analysis
Promela-based UML	Complicated	Effectiveness	One-way	Text	Software Development

Design of Structure

As shown in Fig.5, the structure is overall divided into three layers: portal layer, core layer and interface layer. Portal layer provides interoperable ports and results for users and administrators. Core layer conducts the actual operation and processing while interface layer provides supporting interfaces for internal model language translation and external connections of the measured system and API. Before the execution of analysis, the structure provides modeling interface of authentication protocol by MSCs and interface of attack analysis respectively in view of the white/black box analysis methods. At the end of the white box analysis, the structure shows accordingly the indicators of analyzed authentication protocol, its measurement, and possible attack path depending on feedbacks. At the end of the black box analysis, attack results and available attacker instances will be displayed.

White box analysis. Knowing the authentication protocol in detail, the integrated use of various automated formal analysis tools, such as SPIN, SMV, FDR, NRL and BRUTUS was carried out on the deal. Especially the use of MSC2Promela can be applied to modeling and transformations. By using SPIN, transformed Promela model is analyzed, decreasing the difficulty of modeling authentication protocol so as to improving the efficiency of authentication protocol analysis.

Black box analysis. By the single use or combination approaches of freshness attacks such as type flaws, parallel session attacks, implementation dependent attacks, binding attacks and encapsulation attacks and attacking tools like Ettercap, Achilles, Sniffer, and Paros Jockey, we constructed the platform for attack analysis on authentication protocol to perform the actual attack on unknown authentication protocol.

Indicator system. To analyze authentication protocol, one needs to go deeply through the security nature like confidentiality, integrity, and availability for further research. By giving a simple set of simplified rules to simplify any deduction constraints, a set of "solved-form" that represents all actions of protocol is generated. In the case of finite number of sessions, any deducibility restraint system can be transformed into a simple combination of several "solved-forms". By analyzing the characteristics of "solved-forms", we can decide the main indicators of the protocol and the different indicators according to different authentication protocol.

Conclusions

Methods and tools of formal analysis for authentication protocol have considerably accumulated. Particularly, the application with respect to the SPIN/Promela model checking method is very popular. However, the transformation method based on SPIN/Promela language is in research. This paper described exploringly the transformation from graphical language MSCs to the input language Promela of a universal model checker SPIN, greatly reducing the difficulty of modeling and possibility of making error. Finally, we gave a structure based on the transformation method of authentication protocol analysis, which has certain reference significances for the related work of authentication protocol analysis and validation in the future.

Hot News Recommendation System across Heterogonous Websites Using Hadoop

Shengwu Xu, Zhengyou Xia

Department of Computer Science and Technology Nanjing University of Aeronautics and Astronautics Najing City, China

cocafriend@sina.com, zhengyou_xia@nuaa.edu.cn

Keywords: News Recommendation;Hadoope;Bbig datastyling;Bayesian Mdoel.

Abstract. The current most news recommendations are suitable for news which comes from a single news website, not for news from different news websites. Little research work has been reported on utilizing hundreds of news websites to provide top hot news services for group customers (e.g. Government staffs). In this paper, we present hot news recommendation system based on Hadoop, which is from hundreds of different news websites. We discuss our news recommendation system architecture based on Hadoop.We conclude that Hadoop is an excellent tool for web big data analytics and scales well with increasing data set size and the number of nodes in the cluster. Experimental results demonstrate the reliability and effectiveness of our method.

Introduction

Owing largely to the ever-increasing volume and sophistication of information on the web, we are able to access an enormous amount of information from around the globe[1,2,3].Recommender systems are usually classified into three categories, based on how the recommendations are made[4,5]:content-based recommendation ,collaborative filtering and hybrid. Content-based recommender systems: These recommender systems recommend an item to the user similar to the ones the user preferred in the past [6,7]. Collaborative recommender systems: These systems recommend an item to the user based on the people with similar tastes and preferences have liked in the past. They have the advantage that they can recommend items for which little or no semantic information is available (music, movies, products)[8,9]. Hybrid recommender systems: These systems combine both the collaborative and content-based recommendation techniques in order to improve the accuracy of the recommendation [10].

In this paper, we propose to develop News recommendation system based on Hadoop platform for handling web big data. The remainder of this paper is organized as follows: in section 2 we discuss the architecture of Hadoop. We discuss the news recommendation system on Hadoop in section 3. Finally, we present the results of our experiments in section4.

HADOOP ARCHITECTURE

Hadoop is a distributed file system where files can be saved with replication. It provides high fault tolerance and reliability. The technology has been well received by the community which handles large amount of data. Google uses it for web indexing, data storage, so-cial networking [11]. It is being used to scale up classifiers for mining peta-bytes of data [12]. Data mining algorithms are being rewritten in different forms to take the advantage of MapReduce technology [13]. Figure 1 is the architecture of Hadoop., which is consisted of Name node, Datanodes and HDFS Client[14-15].

1). NameNode : Files and directories are represented on the NameNode by inodes. NameNode records attributes like permissions, modification and access times, namespace and disk space quotas. The data file is split into large blocks (typically 128 M) and each block of the file data is independently replicated at multiple DataNodes (generally three). The NameNode maintains the namespace tree and the mapping of file data blocks to DataNodes.

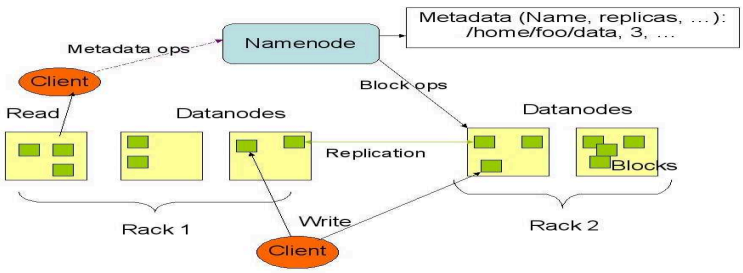

Figure1. Hadoop Architecture [18-19]

2). DataNodes: Each block replica on a DataNode is represented by two files in the local host's native file system. The first file contains the data itself and the second file is block's metadata including checksums for the block data and the block's generation stamp. The size of the data file equals the actual length of the block and does not require extra space to round it up to the nominal block size as in traditional file systems. Thus, if a block is half full it needs only half of the space of the full block on the local drive.

3) HDFS Client :User applications access the file system using the HDFS client, a code library that exports the HDFS file system inter-face. Similar to most conventional file systems, HDFS supports operations to read, write and delete files, and operations to cre-ate and delete directories. The user references files and directo-ries by paths in the namespace. The user application generally does not need to know that file system metadata and storage are on different servers, or that blocks have multiple replicas. When an application reads a file, the HDFS client first asks the NameNode for the list of DataNodes that host replicas of the blocks of the file. It then contacts a DataNode directly and requests the transfer of the desired block.

NEWS RECOMMENDATION SYSTEM USING HADOOP

In this paper, the design of the system is based on the Hadoop platform news recommendation system, which mainly includes several important functional modules. Figure 2 shows the main modules of the system as follows: Data capture engine, automatic segmentation, Semantic, Hbase, Bayesian model. We will detail discuss the main functions and role of these modules. Data Capture Engine is responsible for crawling web data (news or topics) from hundreds of different websites. We design the Data Capture Engine based on Hadoop and the flowchart is as follows. 1) Injector Job: get a group of seed pages from the file, put them to crawl database; 2) GeneratorJob: generate pages to crawl into the crawl queue to grab the database from;3) Fetcher Job: crawl web pages to crawl queue, using the producer / consumer model in the reducer;4) Parser Job: completed pages to crawl parsed to produce analytical results of some new links and web content;5) DbUpdaterJob: the newly generated link the database to be updated to crawl; 6) SolrIndexerJob: be parsed for content indexing.

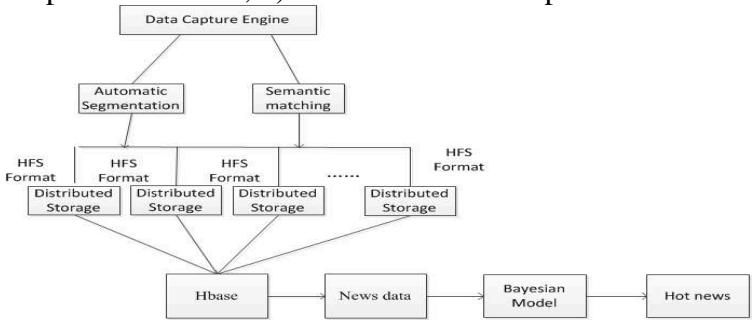

Figure 2. News recommendation system using Hadoop

Chinese automatic segmentation techniques based on "word" as the basis, but not the Chinese written language as a natural separator (space) like the Western text, but in a statement to the characters as a unit, no clear boundaries between words. Idea of the semantic matching algorithm is established in advance thesaurus, let it be according to certain policies will be analyzed. Our system uses and reverse matching methods in this paper. All web data is stored in HFS format and placed in

Hbase database. We propose a novel hot news recommendation model based on Bayesian, which is from hundreds of different news websites. In the model, we determine whether the news is hot news by calculating the joint probability of the news. News headlines are generalization of news contents. Readers often can know the news content through these headlines. This is because news headlines contain highly relevant keywords about news content.Therefore, we firstly preprocess news headlines. In this paper, we use the word segmentation technology to preprocess news headlines. Each headline will be divided into vocabularies with not fixed length and we statistic the frequency of occurrence for each vocabulary. Therefore, we should select appropriate number of vocabularies to analyze the news headlines. Because length of every news headline is different, according to our practical experience data, we select four vocabularies with higher weight as keywords for a news headline (we will discuss the reason of selecting four vocabularies in the next section). For some news headlines, their lengths are relatively short, and could not be divided into four vocabularies. In this case, we add the default vocabularies to these news headlines. The probability of default vocabularies that exist in hot news is set to 0.4, which means that the default vocabularies is not important and is less than 0.5. The 0.4 is set by experience. Calculation equation of hot news probability finally is shown in equation (1).

$$P = \frac{P_1 P_2 P_3 P_4}{P_1 P_2 P_3 P_4 + (1 - P_1)(1 - P_2)(1 - P_3)(1 - P_4)} \quad (1)$$

where, probability of four vocabularies is respectively $P_1 P_2 P_3 P_4$, and P represents the probability of hot news.

EXPERIMENTAL RESULT AND ANALYSIS

In order to verify the reliability of our system we do experiments on real data sets. We collected news from 55 different news websites from 2013.10 to 2013.12, which includes 15243 news. Because there is different updating frequencies from news website, news from different websites have different proportion of the total number of news as shown in Figure 3.

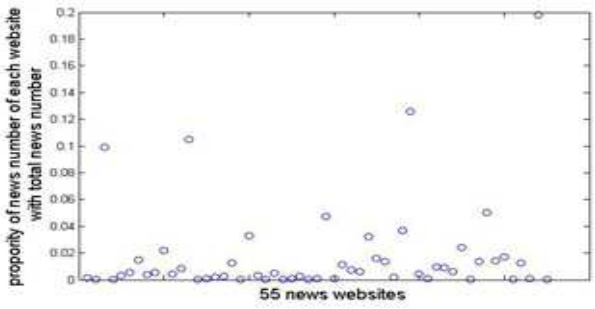

Figure 3. Distribution of news number for 55 different news websites

In Figure 3, only a few websites publish more news . The vast majority of websites publish a few news and the proportion of news number from these websites is below 0.06. This means that the number of news published and updated is less in most websites. We invited five news staffs to select Top 10,20,30,40,50,60,70,80,90,100 hot news from the 2000 news data set. We compare similarity of these two result sets, as shown in Figure4.In Figure 4, when we select the hottest Top 10 news, similarity of the result of our method and human experts is relatively low. Because when the news quantity is less, the human experts' subjective influences will make a difference for hot news. And with the increase of number of news, human experts' subjective influences will decrease accordingly. Therefore, while the number of hot news reaches a certain value, the result of our model and human experts is similar. For these 2000 news, when the Top number of hot news is 100, precision of results are ideal.

CONCLUSION

Hadoop is capable of processing large amounts of data distributed software framework. But Hadoop is a reliable, efficient, and scalable way process. Hadoop is reliable, because it assumes that

computing elements and storage will fail, so it maintains multiple copies of data, to ensure against the failed node can be re-distributed processing. Hadoop is a framework that allows users to use of distributed computing platforms.In this paper, we discuss our new recommendation system based on Hadoop platform and propose our system architecture. We do plenty of experiments on real data sets and compare the result of our model with the result of human news staffs. The experimental results show that our model can effectively extract top hot news from news data sets which are collected from different websites.

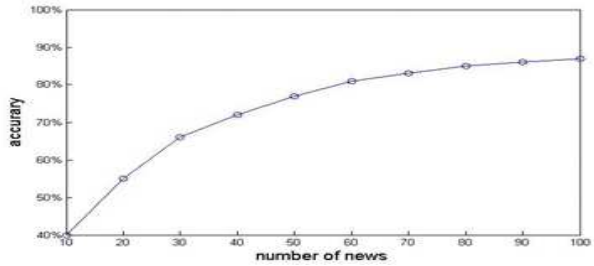

Figure 4. Similarity results of our model and human experts

Keywords: Crowdsourcing QCV model verification

Abstract: With the increase of the scale and complexity of software system software crowdsourcing development have gradually favored by the industry and scholars, to solve the large-scale, large system to develop effective solutions. In this background, this article first introduces the crowdsourcing the basic framework of the development process of software, the basic framework of crowdsourcing and then based on the software development process of put forward a comprehensive software Quality (Quality), the software task Cost (Cost) and software (Value) of a reward QCV model. Finally, this paper, by using data from the topcoder, the QCV process model is verified, it is concluded that the software quality, software cost and interaction relationship between reward.

1. Foreword

Along with asoftware system characterized by growing vast scale and complexity day by day, innovation power and creativity is desiderated in consideration of its demand analysis, function design,functional modeling, code design, functional test and performance evaluation in the development process. In addition, more and more software developers urgently hope their software developed could meet the diversified demands of customers with realized tremendous and multiple functions, which could simulate diversified usage scenario and present the work load distribution of business and measure the acts of employees from various aspects etc. Therefore, crowdsourcing emerges at the right moment in recent years.

Crowdsourcing[1] means a reform of production mode and the software development based on which is to open the process of software development to the public and any software development team and individual could participate in. Its development process is dispersed, which could be allocated to any participant in the development process. Also, it provides some specific mechanism to encourage participants and the participants fulfil the task for the sake of abundant rewards and well-deserved reputation. Furthermore, in crowdsourcing, the mode organizing software development will be transformed from traditional software plants and distributed program development teams to the scattered and mass production mode based on software development ecosystem. Firstly, crowdsourcing opens its development process to the mass organizations on the internet, which means the masses could freely take part in the process shows different open nature comparing from open source. Secondly, it depends on the dispersive development process of the labor force in community.The traditional tasks of software development are often be done by the interior employees of software company or its contractors.However,all the tasks will be allocated to anyone in ordinary people. Finally, outsourcing offers specific rewards to the developers from community and the open source programs usually relies on the fame-oriented volunteers to complete tasks. Consequently, crowdsourcing enlarges the concept of open source community to the software ecosystem driven by market.

Based on the above-mentioned discussion, the text firstly introduces the basic frame of crowdsourcing process and then puts forward a software system model based on crowdsourcing and takes advantage of the data from TopCoder to verify the model of crowdsourcing process.

2. Basic Frame of Crowdsourcing Process

The core of crowdsourcing is to reward the developers in community to participate in mass production tasks and provide software products for the software ecosystem[2]. Therefore, modeling

and the optimization for the modeling for the process of crowdsourcing becomes a focal point of the research. The figure 1 introduces the basic frame including reward system, fame evaluating system, quality assurance system (QAS) and management mechanism of the process of crowdsourcing.

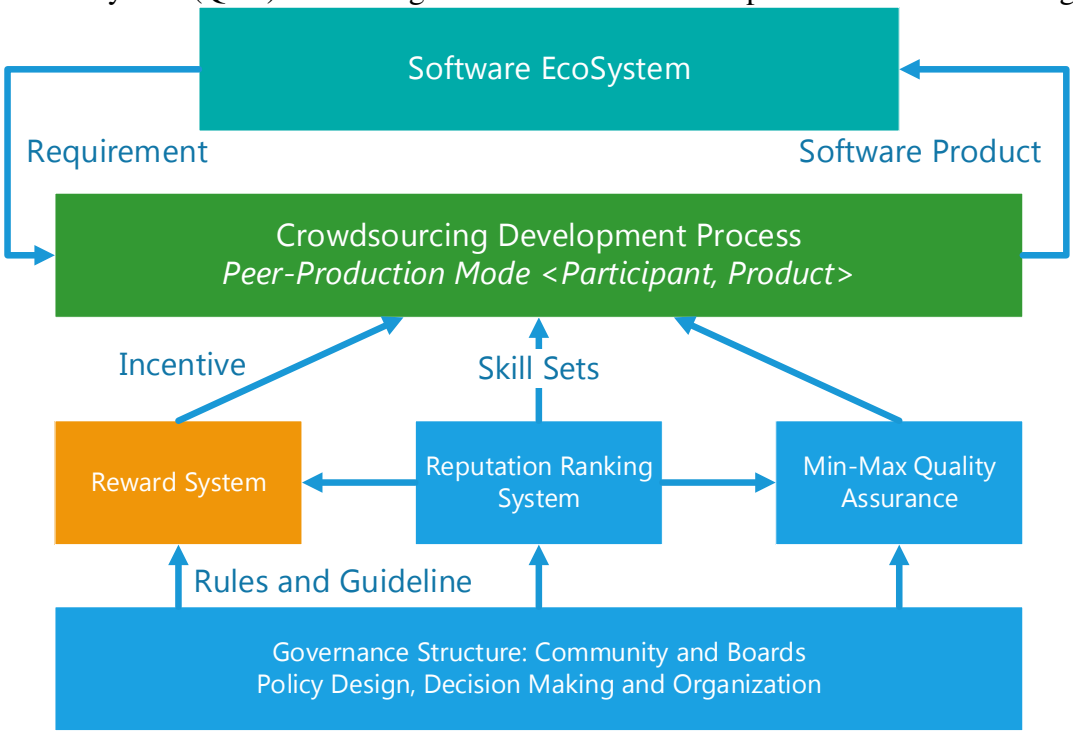

Fig1.Software Crowdsourcingfor developing Software Ecosystem

Management mechanism mainly includes the design of strategy and summary realization, which encourages community people to participate in the development tasks with reward system; ranks the skill of each participant with fame evaluating system;evaluates the products provided and chooses classic ones to software ecosystem with QAS. Crowdsourcing[3] needs an efficient mechanism to encourage the developers in community to participate in its process and provide qualified software products, acting as the major components of the process. Hence, the problem how to optimize reward mechanism becomes the subject we study.

The traditional reward system is designed by taking static business process as the principal thing with limited business environment. However, the systems could not be suitable for crowdsourcing development process and[4] other social computing platform due to the dynamic cooperation modes frequently seen in these platforms and numerous participants. So, in these environments, the results of reward schemes will be even unexpected and claim much higher costs than traditional companies.

3. Crowdsourcing Process Modeling (QCV Model)

The text maps crowdsourcing as a mass production model with competitive mechanism.All software products like demand analysis, scheme design and software composition and so on will be completed through a way of mass production. If there are N development units in the development and they provide M solutions and P products in the crowdsourcing process, manager will select the best one from the P products. Thus, $P \leqslant M \leqslant N$.

So, the optimal object of mass production process is to reduce the costs in encouraging community developers to participant in the crowdsourcing process[5]; enhance the diversity of developers to excavate more innovative ideas and improve the product quality adopted in the end. With the competitive model and optimal object assumption theory, the crowdsourcing process will be modeled. The text puts forward a QCV process model including software quality, task costs and value.

In the competitive relation, each work defined by mass software project could be considered as the work containing competitive nature. Provided that a number of developers take part in the work, the quality of scheme provided by each developer will decide his rewarding possibility[6].

In the QCV model, the text defines$l_{\mathrm{i}} = l_{\mathrm{i}}(\mathrm{Q}_1, \mathrm{Q}_2, \ldots, \mathrm{Q}_{\mathrm{i}}, \ldots, \mathrm{Q}_{\mathrm{n}})$ as developer d_i'possibility in winning crowdsourcing competition when his product is rated as Q_{i}.The$C_i(Q_i)$ is the costs brought by the completion of crowdsourcing task. The $V_i(Q_1, \ldots, Q_n)$ is the reward for the winners[7].

Hence, the income expected by developers is:

$$e_i(Q_1, \ldots, Q_n) = l_i(Q_1, \ldots, Q_n) \times V_i(Q_1, \ldots, Q_n) - C_i(Q_i) \quad (1)$$

When the income expected by developers is higher than zero, developers will have motivation to participate in crowdsourcing. On the contrary, they will not. For simplifying the analysis for the task participation of N developers, we define:

$$l_i = \frac{\phi(Q_i)}{\sum_{j=1}^{n} \phi(Q_i)} \text{if } \sum_{j=1}^{n} \phi(Q_i) > 0,\ l_i = \frac{1}{n} \text{ if } \sum_{j=1}^{n} \phi(Q_i) = 0 \quad (2)$$

Define $x_i = \phi(Q_i)$ and assume $C_i(Q_i) = C_i(\phi^{-1}(x_i)) = r_i x_i$,

The definition of r is the ratio of developers between their costs and winning possibility. So, the r will be determined by the skills of the developers. With the help of Nash Equilibrium Theory [1], the developers in the process of crowdsourcing could be divided into active and passive ones. For the active m developers, the formula $\forall r_i\, i = 1, \ldots m, \sum_1^m r_j > r_i(m-1)$ is to describe competitive mechanism. Let's assume ten developers take part in the mass production competition.

Assume$r_i = \sigma \times i,\ \ i = 1,2, \ldots 10,\ the\ \sigma$ is the minimum spacing in quantizing r_i.

m>1

Thus,$\frac{\sigma m(m+1)}{2} > \sigma m(m-1)$ (3)

Hence, m<3.That means two developers will do active contributions to the task.

Let's assume r obeys two distribution patterns like uniform and normal ones. When the number of competitors changes, the corresponding number of m could be calculated and a changing curve of m following n will be drawn accordingly.

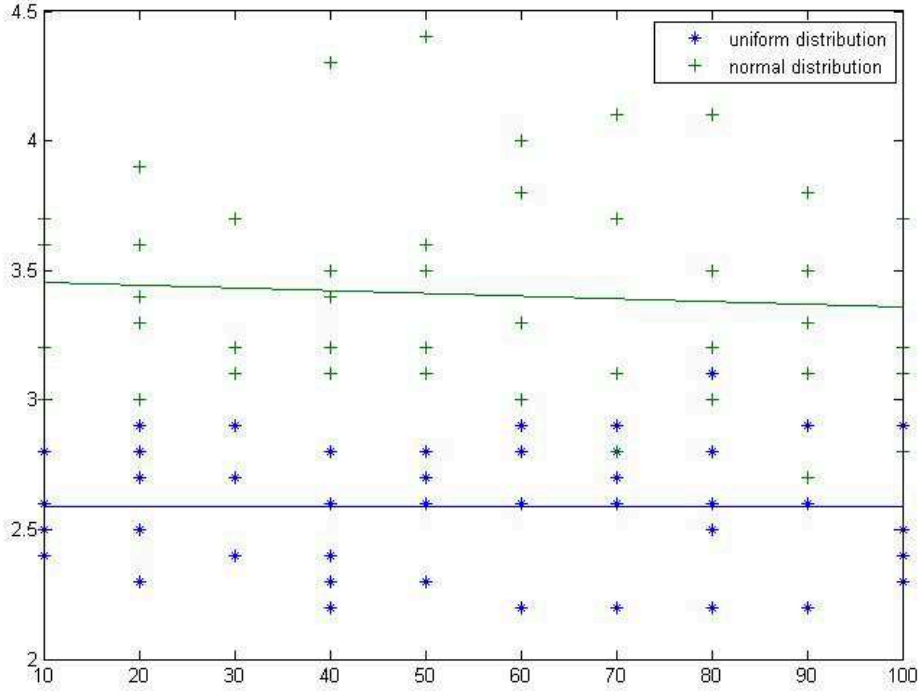

Fig2 M-value under different R values (uniform vs normal distribution)

Known from the figure, based on the QCV model, the range of value m is 3-4.5 when the value of m is determined by the distribution of r and ther obeys the normal distribution$r\sim N(0.5,1)$.When r obeys uniform distribution $d\sim U(0,1)$, the value range of m is 2-3.

4. QCV Model Verification

Based on the above model, the text verifies the data from the TopCoder and the data sets include 1734 software design cases and 910 software development cases. With the data sets, a changing curve is simulated and drawn including registrants, the schemes submitted and the reliable scheme number following rewards.

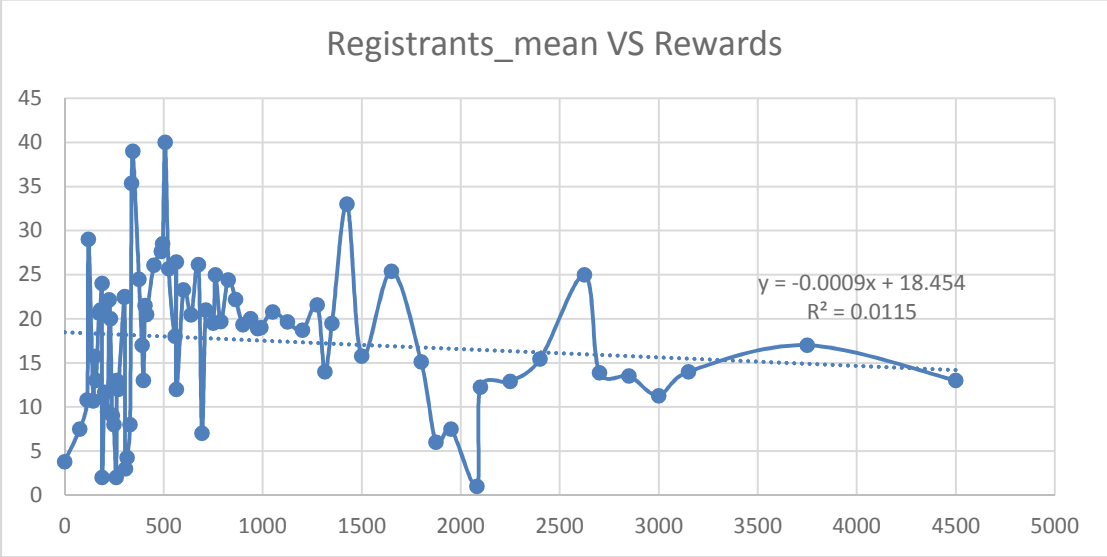

Fig3. Registration-Reward Curve in Development contests of TopCoder

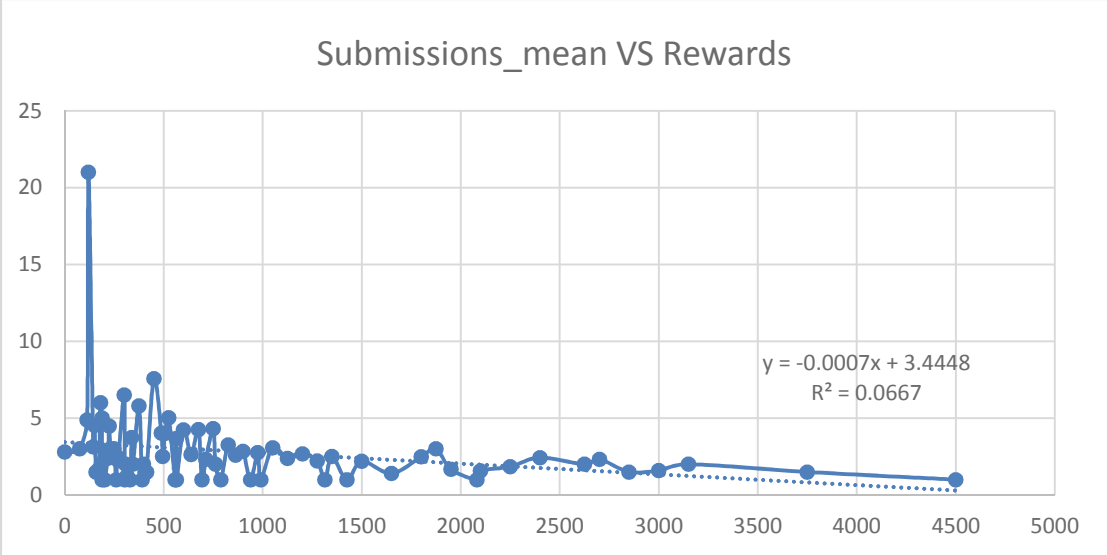

Fig4.Submission-Reward Curve in Development contests of TopCoder

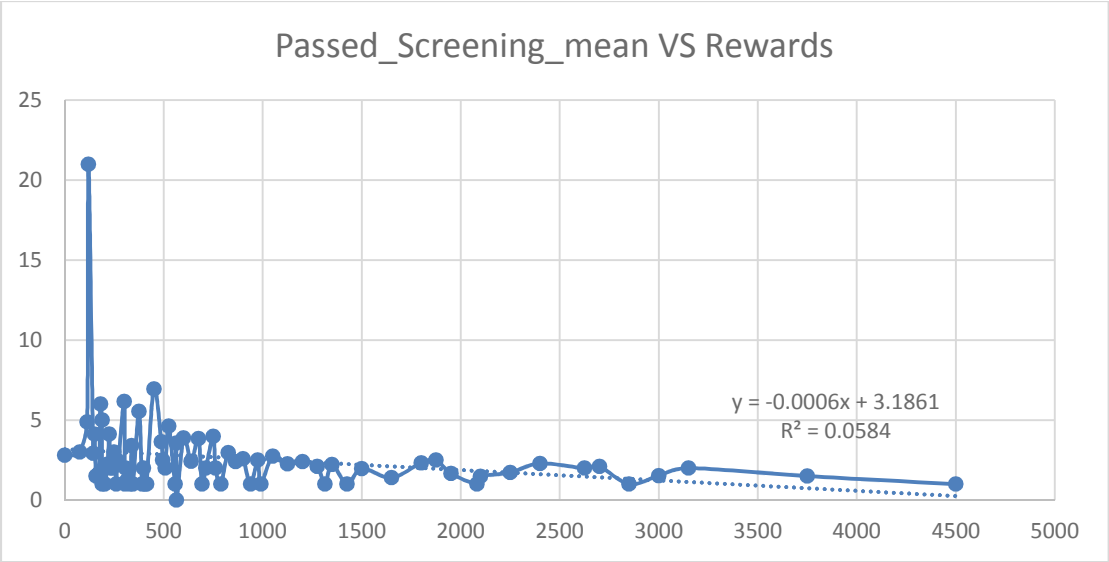

Fig5.Effective-Reward Curve in Development contests of TopCoder

Obviously, the qualified products number submitted finally is greatly less than registered ones. Meanwhile, bonus amount shows little influence to the motivation of the workers in community and more bonuses shall not bring about more participants. According to the statistical data from TopCoder, the average time for completing the tasks of TopCoder is about two weeks. So, those urgent challenging tasks and time limit may make most developers feel too much risk. For this reason, more data is needed in verifying it.

5. Conclusion

Based on the discussion for the crowdsourcing process, the text raises a QCV model including quality, cost and value.Then, taking advantage of TopCoder, the text verifies the QCV process model and gets the mutual effect among software quality, costs and rewards.

Keywords: E-Government 2.0; Basic Government; Public Service

Abstract: Although the construction of E-government in our country has advanced into the era of E-government 2.0 from E-government 1.0, whose development greatly promotes the integration and improvement of governmental public service and management ability. Basic government is the main supplier of lots of public services,and for basic government,using E-government 2.0 to provide and to improve public service is an important mean to improve service quality and efficiency.However,in practice,E-government still faces obstacles in aspects of concept,institution and resource in the application of basic public service.Eliminating these obstacles,and promoting E-government 2.0 to function,will further improve the efficiency and level of basic public service.

Introduction

The so-called "E-government 2.0",is to apply one or several kinds of techniques of Web2.0 in E-government[1].E-government is a platform and mode where application information communication technology conducts network integration and flat management of public management matters,and government can use E-government to reform traditional government into electronic government.The incipient E-government cannot satisfy technically the interaction between the public and the manager,which can be achieved by E-government2.0,thus achieving electronic service which confronts the public and orients the public as the core.

1. Application of E-government2.0 in Basic Public Service

E-government2.0 applies new concepts and technical support of Web2.0,improves the efficiency of basic government, and transforms the relation between the public and government.E-government2.0 is the upgraded version of E-government1.0.E-government2.0 will not only link government departments with each other,government with enterprises,and government with the public through network communication technology,establish a new ,interactive and ever-present service form,but also achieve one-station and timely public application platform around satisfying public demand.At the same time government can also publish information by E-government2.0,obtain various feedback information and the demand for service of the public,manage public matters and provide public service. The specific application forms of E-government2.0 in basic public service are shown as following aspects：

1.1 Information Release Window of Basic Public Service

The function of government portal website is to publish public service information,but the current construction of electronic government certainly demands fundamental construction and development in the prophase of E-government,which makes closer information transmission window relation between E-government construction and information platform,and thus is beneficial for the achievement of mutual assistance function between the two.Basic public service relies on government portal website to publish and to open up public service and public policy through the medium of information service,thus making cut the distance between government and the public,which delivers duly social service value loaded by information service.For instance,RSS in E-government2.0 is a kind of Web2.0 content syndication format and possesses a set of bidirectional and interactive linkage applications program which can achieve Web content among

content consolidators,content providers and final users.If the public relies on RSS service in E-government,the public takes RSS reader as carrier to browse and to criticize views,policies and regulation,etc.of government,thus establishing electronic service information integrated world of society and government.

1.2 Coordination Office Platform of Basic Government Departments

E-government takes information technology of that period as carrier,and merely drives directly the artificial way into automation stage.It is thus clear that the process is to extract operation staff from the stage of conducting repeated work step by step,and then to simplify its work layer and to perfect work flow[2].Through using network technology such as Blog,Wiki,etc.,on the basis of E-government1.0,E-government2.0 will establish some inter-departmental and inter-organization communities.It will rebuild business flow,and thus conduct foreground government integration of original decentralized government.And it will also conduct cross-foreground-background cooperation and inter-departmental coordination office of background business departments drove by service administration.For instance,administration service center,one-station service and citizenry card are all typical cases of applying cooperation office mode.

2. Obstacles of E-Government2.0's Application in Basic Public Service

The application of E-government2.0 in basic governments can strongly promote the quality an efficiency of basic public service. However,in practice,the whole application rate of E-government2.0 in basic public service is low,and the application of E-government2.0 of basic governmental departments is insufficient,and governments are still accustomed to the traditional monomial mode where governments provide public services directly to the public.E-government2.0 cannot function fully because of the presence of obstacles in the aspect of concept,institution and resource.[2]

2.1 Conceptual Obstacles of E-Government2.0's Application in Basic Public Service

The leaders and the administrative staff do not value sufficiently E-government2.0,and are affected by official standard and the thinking of monopoly on governmental information,thus making low the degree of E-government's usage in basic governments.Affected by traditional administrative culture,bureaucrats in basic governments do not change official-standardized thinking fundamentally,whose bureaucracy and privilege thinking are ingrained.In their thinking,they think that the government rules the people,so they are accustomed to regulating the public rather than providing service.The construction of government portal websites-as the carriers of E-government public service-do not reflect the central concept which takes the public as the core and serves the public,but the social public service information cannot be found. The most prominent flaw of basic government's portal websites is that the content is incomplete, and the update speed is slow,and the websites cannot meet the timeliness demand of the public for information.Some basic government's websites also set columns such as message boards for communicating with the public,but many comments and problems of the public do not receive timely treatment,which cannot function to communicate with the public.On the one hand,basic governments's monopoly of information makes congested the way of public participation in administration and discussion of politics, which cannot know the demand of the public,thus causing the divorce between administrative decision and real demand,and poor effect of implementation.On the other hand,information disclosure is limited,and the public cannot effectively supervise government's administrative activities,thus making possible the abuse of administrative power.

2.2 Institutional Obstacles of E-Government2.0's Application in Basic Public Service

Institutional obstacles of E-government2.0's application in basic public service are shown in two aspects including segmentation of trap and block of governmental organizational mechanism and disperse information.Current governmental administrative structure in our country is matrix organizational structure,however,what must be considered is that matrix structure under segmentation of trap and block will certainly increase node departments and possibility that the local protectionism of departmental head occurs,thus causing further the phenomenon of institutional corruption.At the same time,each node department will formulate decision and take

action from their own interests,and every government and every department are insufficient in interaction and communication,which causes the increase of administrative cost and the decrease of administrative efficiency. Fragmentation among governments is not conducive to the construction and development of E-government2.0.Each department uses different standard from their own business demand,thus causing the phenomenon of information interaction absence among each node department and between upper government and basic government,and thus finally making relatively low sharing degree of public service information.E-government2.0,a systematic and compositive program,needs a unified plan to achieve the sharing of information resources .Meanwhile, absence of sharing system of public service,will certainly affect the construction process of E-government2.0 in basic government,and will also cause lots of repeated construction and waste of resources.

2.3 Resource Obstacles of E-Government2.0's Application in Basic Public Service

Resource Obstacles of E-Government2.0's Application in Basic Public Service are shown in the absence of material resources and human resources.On the aspect of material resources,because of insufficiency of basic government's monetary expenditure,insufficiency of investment of hardware and software,and,the backwardness of electronic information facilities in remote region such as villages,application rate of E-government2.0 is low,which causes each government to provide service mainly by traditional method and to be unable to represent convenient and timely effect of network service.The basic government's construction of database is not mature enough,and data is incomplete, and information is confused,and,the update and maintenance of database are insufficient,which causes the absence of vast information and the disarray of management,thus making the level of public service low.[3] Because internet coverage rate and home networking rate in remote areas such as villages are low, acceptance of network path of government information is low,thus making inaccessible to obtain network service and even more to participate in government-society bidirectional management through the network.Requirements of E-government2.0's construction for administrative staff is not only to master the basic knowledge of computer operation,but also to possess some application skills of E-government software system.However,currently,staff who can apply proficiently E-government operating system are very small in civil servants system of basic government .

3. Measures to Promote the Application of E-Government2.0 in Basic Public Service

Conceptual, institutional and resource obstacles of E-government2.0's application in basic public service seriously hamper the development of basic public service.The advanced technology of E-government2.0 cannot be capitalized fully and cannot reflect its advantages.Therefore to make efforts in the following aspects eliminates obstacles of E-government2.0's development,in order to create conditions for improving level of basic public service.

3.1 Transforming Service Concept of Basic Governmental Service

To transform consciousness of government departments and the role location,converts from original administration into service.E-government2.0,taking the public as the dominant,provides new concepts for basic government.When basic governments take advantage of E-government2.0 to transform governmental functions,basic governments need to consider demand of people, in order to better provide the most urgent service for people.When governments formulate policy and make decision,governments can take advantage of political and public communication channels to carry out research, solicit public opinion,know public demand,and optimize constantly basic public service.[4] Basic government should set up a transparent administrative concept,to let the government's rights operate under the sun.Basic governments should make greater breakthrough in information disclosure,and open up all information which can be published to the public.The application of E-government2.0 provides smooth, convenient channel for the public to obtain government information,and satisfies the citizen's right to know and participate.Basic governments through E-government2.0 expose behaviors under the sun, conducting transparent administration.

3.2 Promoting the Cooperation among Basic Governments and Realizing Information Sharing

Cooperation among basic governments facilitates the sharing of information between the government and the Department and the information sharing among institutions will promote the smooth development of cooperative service among basic governments,both of which are mutually functional and mutually stimulative relation.To improve the level of information sharing,needs to make efforts in two aspects.On the one hand, the depth and breadth of information resources are the key task in the current information construction.Public service of basic governments should establish a wealth of information database through collection and integration of information,expand the amount of information and optimize quality of resource through resource allocation,and establish information base about population, cadaster,economy, community, environment and transportation,etc.to provide a rich source for information sharing.On the other hand,establishing the integrated information resource management system unifies data standard and operation mechanism,to let governments at all levels and each department obtain the data they need in information database and to reduce administrative cost,and to improve administrative efficiency.

3.3 Increasing Investment and Enriching Material and Human Resources

The central authorities and basic governments at all levels should increase the investment of developing E-government,for the rural areas set basic hardware and software facilities,and comprehensively realize online office of basic governments,thus further developing towards E-government2.0 system.Equipping with professional technical staff to help basic governments to establish the basic information database about population,cadaster and economy,etc.,ameliorates the situation of information absence.Country should accelerate network covering every village project,to let farmers surf the Internet home and share equally network service with city residents.The lack of professional E-government talents in basic governments is caused mainly by two reasons:firstly,the supply shortage of talents and secondly,the neglect of E-government skills in civil servants selection.Therefore,to meet the demand for E-government human resource should begin from the two aspects.On the one hand,to increase the supply of professional E-government talents can be achieved through school education and on-the-job train.School education is to set up major and courses related to E-government in colleges and universities,which lets students master the basic knowledge of E-government and smoothly conduct online office when they enter into governments afterwards.E-government2.0 can promote the improvement of level of basic public service,and thus further promote the construction of service government in our country.Currently,in our country,the development of E-government in central authorities and provincial and municipal governments is relatively fast.Therefore what should be done is to move the construction center of E-government2.0 down into base course,which realizes comprehensive and balanced development from the top to the base,and which accelerates the construction process of government administrative information,modernization and service in our country.

Keywords: Big Data;Cloud Computing;E-government

Abstract: Big data is an emerging concept in the field of computer and E-government recently,but research institutions and scholars have different opinions in the content and understanding of big data.In the era of big data,E-government is facing great challenges and tests,and the processing of complex data in the era of big data will become the main theme of the development of E-government in our country.Through analyzing processing mode of big data,and on this basis,this thesis discussed the influence of the era of big data on the development of E-government,in order to find an effective path under the mode of big data to develop E-government.

1. Overview of Big Data and Big Government

1.1 Big Data

Big data is an emerging concept in the field of computer or E-government.For the content of big data,enterprises and the academic circles have not yet formed an accurate definition.Wikipedia defines big data as "a collection of data sets so large and complex that it becomes difficult to process using on-hand database management tools or traditional data processing applications"[1];the authority of IT research and advisory consulting company Gartner defined big data as"a matter of extreme information management and processing,which exceeds the processing capacity of traditional information technology in one or more dimensions "[2];moreover USA National Science Foundation(NSF) defines big data as "large-scale, diversified, complex, long-term distributed data sets generated by various data sources including scientific instruments, sensing devices, the Internet trading, e-mail,audio and video software, web click stream "[3].

1.2 Big Government

Now the development of E-government has brought many new changes.In the past the E-government is the application using the Web1.0 by PC computer connected to the Internet,while now along with the development of information technology including mobile Internet,the Internet of things and cloud computing,etc.,and the popularization of mobile terminal equipment,more network application and a large amount of data have been produced,indicating the arrival of the era of big data.Under the context of big data,E-government will certainly move on to a new stage,i.e. the stage of "Big Government".Big government can be defined as:in the context of development of new generation of information technology including mobile Internet, Internet of things, and cloud computing,etc.,along with the context where increasing mobile terminal equipments and increasing software applications produce a large amount of data,the government makes full use of the change of the context(mobility,openness),uses a variety of techniques of the era of big data,has the aid of the character that the analysis techniques of big data locate precisely, achieves the optimization and reorganization of the governmental organizational structure and the work flow,exceeds the limits of time,space and department separation,and establishes a streamlined, efficient, honest, fair governmental operation mode,so as to provide high-quality,standardized,transparent management and service conforming to the international standard in all directions."Big Government" is the manifestation of E-governmental "Big Wisdom",and will better support the national wisdom city construction.Moreover relying on big data to construct the "Big Government",the method's advantages and characters are showed in Figure 1.

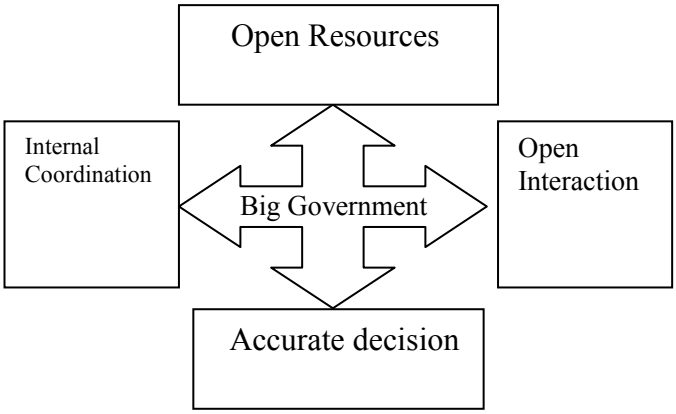

Figure 1 The advantages and characters of Big Government

1.3 the Relationship between Big Data and Cloud Computing

Big Data and Cloud Computing complement each other.Cloud Computing is the IT basis of Big Data,and Big Data is a killer application of Cloud Computing.Cloud Computing is the driving force for growth of Big Data.In the other hand,because data are becoming more and more complex and increasingly real-time,it is more necessary for mining,analyzing and processing.

At present,Cloud Computing has popularized and become the mainstream technology of IT industry.Its essence is a basic architecture and business model generated in the demand context where computation becomes more and more huge,and data becomes more and more,increasingly dynamic and increasingly real-time.

The emergence of Big Data is causing worldwide profound transformation of technology and commerce.On technology,Big Data has changed the conventional way of extracting information from data.In the field of technology,in the past relying more on the way of model,now we can borrow large scale of data,and use method based on statistics,hoping to make new progress in areas including speech recognition, machine translation in this Big Data era.On the business model,for the participants of commercial competition,Big Data means the exciting innovation opportunities of business and service.Retail chain enterprises and electric business tycoons have had a lot of successful cases in big data exploring and marketing innovation.

Overall,Cloud Computing and Big Data differ mainly in two aspects in application:Firstly,they are different in concept.Cloud Computing changes IT,while Big Data changes business.However, Big Data must have the cloud as infrastructure to smoothly operate.Secondly, the target audience of Big Data and Cloud Computing is different.Cloud Computing is the technology and product sold to CIO,and an advanced IT solution.However Big Data is the product sold to CEO and business layer and the policymaker of Big Data is business layer.Because they can directly feel the pressure from market competition,they must beat rivals by means more competitive in business.

2. The Processing Mode of Big Data

The processing mode of Big Data evolutes from traditional database cluster to Cloud Computing MapReduce massively parallel processing structure,and achieves the decomposition process of task and the merger of result,so as to achieve unlimited extension of scale of disposable data. Barge Data processing techniques have been considered another subversive technological change after cloud computing,Internet of things in IT industry.

2.1 Mode of Database Cluster

Cluster means loosely-coupled sets of computing nodes which constitute from running the same set of applications through the cooperative work, providing a single system image for clients and applications,and using specific way of connection to make hardware equipment combined.It has the following advantages:performance lifting,extensibility lifting,reliability lifting.Database cluster introduces the cluster technology into the database[6].Database cluster has some limitations in technology,specifically introducing as follows:

Using PC server as a function node,too many system cables,too high complexity of hardware,and pretty difficult implementation of erection,make extensibility limited;High speed interconnected devices must be connected with main engine through the PCI of main engine,but the transmission rate of PCI cannot meet the demand of data communication among the nodes of parallel database cluster;Space for improvement of the database security and extensibility of data sets is minimum,and four technical indicators including all-round speed promotion,data synchronization,security guarantee,and extensibility,are huge problems;As the increase in amount of equipment and the complexity of application,it is necessary to rapidly superadd investment to solve all kinds of problems of compatibility and reliability,etc.;Parallel database mainly uses shared-nothing structure,and is insufficient in aspects of extension, fault tolerance, cost, and ability to support heterogeneous environment and interacts,thus extensibility is very limited and at present, there is still no application case of a scale of thousands of nodes.

2.2 MapReduce Framework Mode

Cloud Computing Structure forms server cluster by large-scale low-end servers, provides vast storage space and processing capacity of large-scale data,and has reliability, extensibility and high availability.Therefore electronic business platforms including Institute of Computing Technology, Chinese Academy of Science(ICT),China Mobile,Baidu,Taobao and Netease, use mainstream Cloud Computing platform-Hadoop Structure-to conduct Web search and analysis of Big Data,etc.MadReduce Structure includes:Distributed File System(HDFS),Parallel Programming Model MadReduce,and Parallel Execution Engine.

From the perspective of HDFS,Hadoop's node consists of data node which stores and provides location service, and name node which manages namespace of distributed file system.Structure design of HDFS host-guest structure greatly simplifies distributed system structure.The design features of its file system:centralized management of metadata,scattered storage of data block（64 MB） to guarantee security of data,and data replication(at least three backups for every data) to achieve high fault tolerance[3].The traditional database system has high real-time responsibility,but for Big Data of Class TB or Class PB,search speed of data mining fells sharply.However introducing mechanism where HDFS and RDBMS combine can make full use of advantages of the two,and achieve highly-efficient data mining and decision support[9].

MadReduce,designed by Google and used to process parallel computing on big data sets of cluster,is a typical representative of non-relational data management and analysis technology.MadReduce makes data processing task abstracted into a series of map and reduce operation, completes respectively filtration and aggregation operation of data,and conducts management through simple interface.Simply put, its calculation process and basic principle are to make big data sets decomposed into hundreds of small data sets,each(or some) data sets processed by a node of cluster and to generate intermediate results.These intermediate results are merged by a lot of nodes,and form the final results. As shown in Figure 2.

Main coding work,based on computing model writing distributed parallel programs ,is to achieve map and reduce function.Other complex problems such as distributed storage, job scheduling,load balance,fault tolerant processing and internet communication,etc.,is in the charge of MadReduce to process.MadReduce has simple principle,simple technology and high efficiency in data processing,and in the system level solves the stubborn problems of database cluster such as extensibility, fault tolerance.MadReduce opens resource for free,builds large-scale cluster elastic to stretch out and draw back on the basis of heterogeneous cheap server,and processes and analyzes large-scale data parallelly in distributed way.Its cost of construction is far lower than that of parallel database used by database cluster[9].Comparative analysis of several kinds of big data processing mode is shown in Table 1.Therefore MadReduce big data processing mode has relatively noticeable advantages.

Table 1. Comparative analysis of big data processing mode

Character	Database Cluster Mode	MapReduce Structure Mode
Extensibility	very limited, hundreds of nodes	extensible to exceed platforms, thousands of nodes
Integrity	poor on fault tolerance,task processing,and disaster recovery	high fault tolerance,robustness
Security	failing node to affect entirety	failing node not to affect entirety
Flexibility	low	high
Data Processing Ability	mainly supports structural data	supports complex data processing,including structural data and non-structural data
Processing Efficiency	relies on optimized distributed programming design	high
Heterogeneous Storage	unsufficient	highly supportive
Cost	high complexity of hardware, and rapid increase of additional investment	low demand of hardware, and low cost of extension

3. The Influence of Big Data on the Development of E-Government

The development of big data will greatly change the managerial mode of government.Its inclusiveness will blur the borders among various government departments and between government and citizenry.The phenomenon of information island will reduce greatly,and data sharing becomes possible,thus improving coordinative office efficiency and civil service efficiency,and promoting the government's ability of social management and public service.Specifically, relying on the development of big data will be in favor of saving government investment and strengthening market supervision,thus improving the decision-making ability of government,promoting ability of public service and realizing regional management.

Capitalizing big data to integrate information and to share and compare enterprises fundamental information collected by departments such as Department of Industry and Commerce, National Tax Bureau, Local Tax Bureau,and quality inspection department, through analysis,can discover regulatory loopholes,raise the level of law enforcement and achieve the objective to promote fiscal income and to improve the level of market supervision.Establishing the center of Big Data,strengthening the acquisition, organization, analysis, decision-making of government data,achieving unified management of large data for government information resources by Cloud Computing Techniques,and conducting exploitation and utilization of government resources according to the laws and regulations and the demand of each department,can improve the utilization rate of equipment resources,avoid overlapping projects and reduce maintenance cost.

Big data will also further improve the efficiency of decision-making,improve the accuracy and scientificity of government's decision-making,improve the government's ability of forecasting and warning and of emergency response,and save cost of decision-making.Taking the fiscal department for example,on the basis of Cloud Computing and Big Data Techniques,the fiscal department can handle data of every department according to demand and analyze the data.Thus the decision can be more accurate and more efficient.In addition,the fiscal department can also promote fiscal innovation on the basis of data,thus making fiscal work more efficient,more open and pore transparent.Capitalizing Big Data,can also gradually achieve three-dimensional, multi-level, comprehensive public service system of E-government, promote openness of information,drive service functions such as real-time receiving online service,cooperative sector management and feedback on the Internet query, accelerate the intelligent E-government services and preliminary application of mobile E-government service new mode,expand personalized service constantly,and further enhance the direct two-way interaction and synchronous communication among government,society and citizenry.

Management based on city grid requires a unified and coordinated integration of management information,and all kinds of basic resources and information should be shared commonly.Big Data can achieve that.By making full use of various resources of Big Data,playing the managerial utility of city grid will achieve the greatest degree of shared application,in order to improve the service

quality city and community, to improve the service ability,to strengthen the service management and to create a service-oriented society,thus making the level of city management and community service to a higher class.

4.In the Era of Big Data the Development Path of E-Government in Our Country

Although at present the information sharing construction based on Big Data in our country was partly successful.However,in general,the cross-sector utilization system of information resource is still limited in small parts of the government's business scope and, the depth and breadth of applications are still far sufficient,which cannot meet the requirement of development of modern society.Therefore we need to conform to the trend of Big Data,build online business hall,exchange and sharing platform, social credit system,disaster recovery backup system and open platform on the basis of Big Data,build Cloud Computing platform of government,and actively promote the construction of E-government.

Building Province-Municipality-County tri-level unified online business hall which sets information disclosure, online processing, convenient service, electronic monitoring in one,by virtual service window,provides one-station, cross-regional, all-weather, and transparent various social service and management matters.At the same time,promoting all classes of substantive administrative service hall to move to online business hall,achieves effective integration of cross-department online matters and promotes online affairs of the whole process.

Entirely building Province-Municipality-County tri-level exchange and sharing platform of Big Data,perfects the coverage of exchange and sharing platform,opens up the horizontal and vertical sharing channel of information,and promotes cross-regional,cross-department information resource sharing and business collaboration.At the same time,perfecting information resource catalog system of the whole province,formulating information resource sharing catalog of the whole province and data criteria,and strengthening the integration of various information resources,provide cross-layer,cross-department data support for provincial,municipal and county governments to deepen the application of E-government.Building mechanism of exchange, integration, comparison, update, maintenance among data centers and among database of all-class government,and building fundamental database of natural person, legal person, spatial geography,etc.,provides data support for social management,public service and macro-control.

Integrating credit and information resources from government functional departments,enterprises and institutions, guilds, and intermediary organizations,and promoting and regulating the construction of credit institution,provide complete, accurate, and timely credit information of enterprise and individual.At the same time,building individual credit information platform, exploring the construction mode of individual credit system,and promoting the exploitation and utilization of individual credit information,lay a solid foundation for building credit society.

Carrying out the top-level design of E-government public service platform based on Cloud Computing,and building centralized and unified regional E-government Cloud platform,provide server resources, huge storage space, high bandwidth of network and safe network environment for government departments.E-government Cloud platform will be built in accordance with unified criteria,which can be plug-and-play.Government departments can also customize and use the E-government Cloud platform according to their own demands.Creating a new situation where information is shared jointly,and resources are shared jointly,and operation and maintenance are managed jointly, gradually achieves the goal that government departments unify server management,generator room,operation and maintenance,in order to fully integrate resources, improve utilization rate of resources,and reduce overlapping investment.

Building disaster recovery backup facilities,provides unified disaster recovery backup service for users of party and government.Through techniques such as data backup and data duplication,achieving data-level disaster recovery, ensures the integrity,consistency and availability of business data of each department.At the same time,achieving fast-switching and zero-data-loss application-level disaster recovery for some important application system,thereby provides disaster backup and recovery service of network,data and application system for government departments of the whole province.

5.Summary

Through construction of Big Data center,after processing summary, cleaning, comparison and analysis of government department's data,forming information resources and building a public platform of Big Data, hence open up government data jointly to society and promote exploitation and utilization of information resources by the whole society.

Keywords: EPON; topology discovery; topology management; memory management

Abstract

The network bandwidth has been expanded after EPON(Ethernet Passive Optical Network)came.So a topology management for EPON System is needed.In this paper, methods of topological data collection is analyzed, the form of topological data structure object is designed , and topological structure is displayed in the terminal by coding. With introducing in improved memory object and caching techniques, system performance was significantly improved through experiments.

Introduction

EPON(Ethernet Passive Optional Network)solve the problem of limited access network bandwidth.Integrity and vitality of the network topology plays an important role in performance inspecting, event analysis ,fault localization and resource management in terms of network management.Also,it responses to the network service quality intuitively.

Idea of Design

Function

Topology management features include :

1.Topology Discovery, to automatically search the entire EPON network for OLT(Optical Line Terminal) and ONU（Optical Network Unit)and so on ,which support the SNMP,and get informations about the devices.

2.Topological construction, to construct the logical topology graph consistent with the actual network topology in network management system,according to the informations we get.

3.Topology display,to build a topology form of memory objects by informations that found ,and display to the user in a graphical way.

4.Topology edit,users can operate easily and intuitively,including creating a domain, creating a group, creating OLT network elements,creating segments and creating ONU device operations.

Architecture

Topology management is designed as three layers :data acquisition layer, data manipulating layer, and topology display layer. Data acquisition layer is responsible for collecting topology data,including informations of the status of the devices and informations of topology between them,supporting data acquisition methods of multi-thread, multi-point collection and multi -gathering instrument.In data manipulating layer ,the topology data is filtered and assembly to the

topological data structure object needed by topology display layer,and then be passed to the foreground display layer.Topology will be displayed in various styles in topology display layer. Fig. 1 shows the architecture.

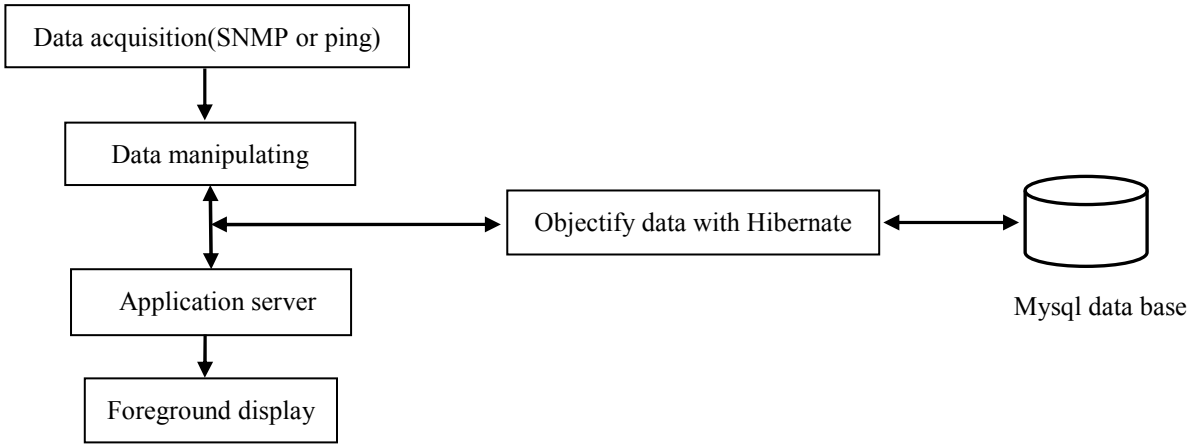

Fig. 1 Topology management architecture diagram

Realization and Improvement

Memory Objects and Database

Data model will be used in interacting with the database persistence layer by business logic layer of the system and foreground display,known as memory object. Memory object is used to implement a topology memory object data model, including *Domain,Group,TopoNeInfo,CardInfo,PortInfo,TopoLinkInfo,OnuDiscoverInfo* and *OnuSearchFilter* etc.Let's take *TopoNeInfo* for example.

As a network element memory object,*TopoNeInfo* inherited base class *BaseObject*,and has properties and behavior of a normal network element *NeInfo*,also it has its own character such as coordinate positions etc.

Design of the table of the database(Mysql) contains all of the memory object corresponds to the data model.Table 1 describes *Domain* as a database table.

Table 1 Database table of *Domain*

Property / field name	field type	field description
domainId	varchar(255)	primary key
domainName	varchar(255)	Domain name
xCoordinate	long	Coordinate x
yCoordinate	long	Coordinate y

How to Realize

Fig. 2 is a flowchart of topology discovery algorithm ,which discovers OLT and ONU devices and their interconnection in the network of EPON.

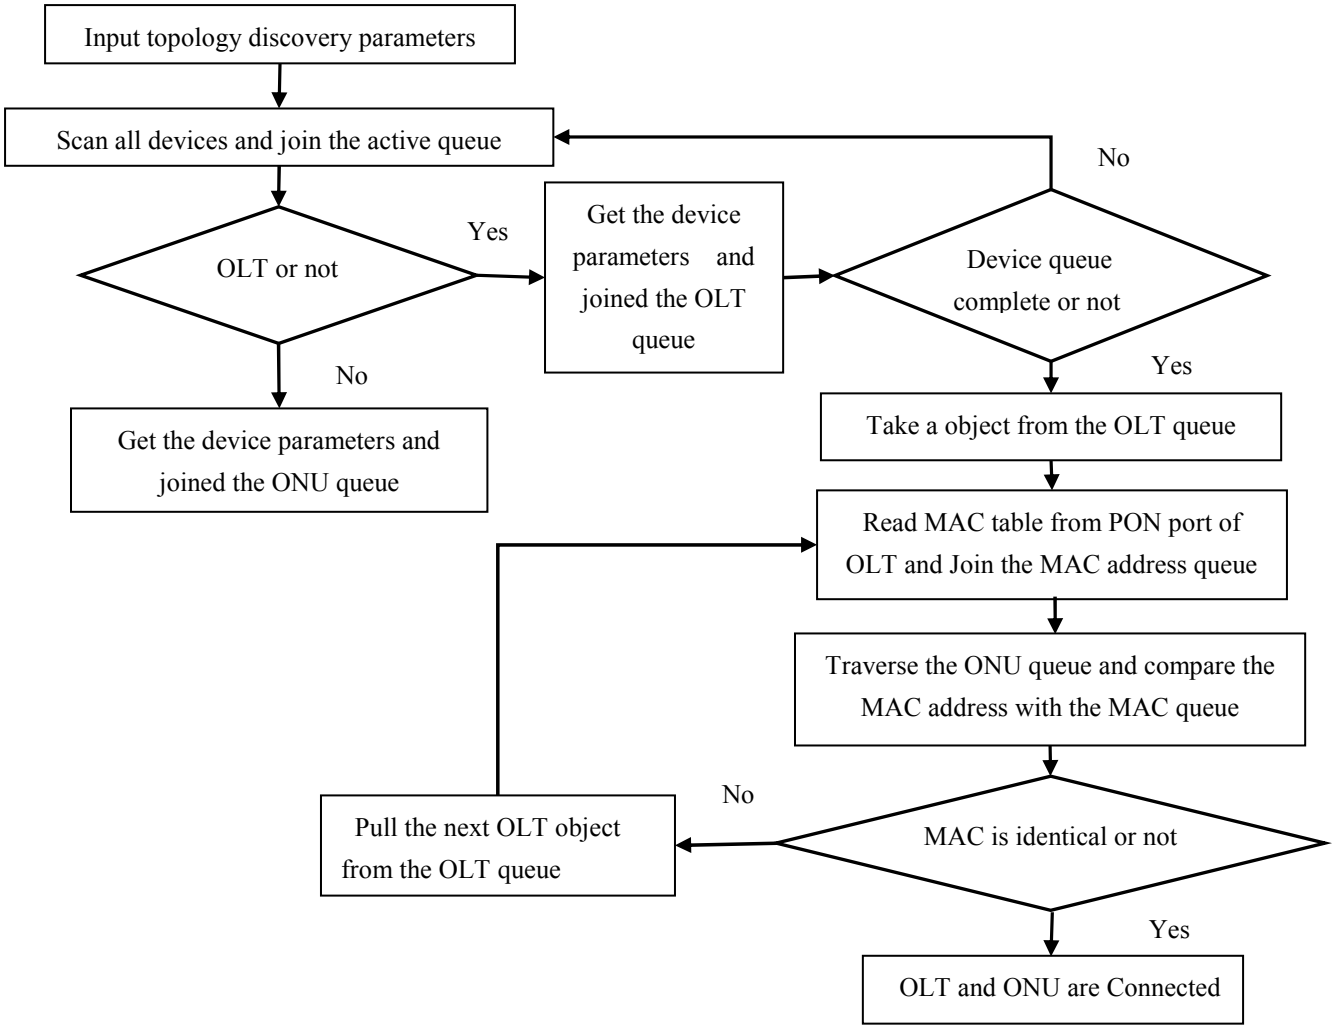

Fig. 2 Flowchart of topology discovery algorithm

In this topology discovery process,ICMP and SNMP are used as data acquisition method. Device state information can be quickly got by *ping* method of ICMP ,and more information about the device can be received by means of *get* method of SNMP.

Gateway network element successive discovery of topology is the method used to discover topology rapidly. First,get the NNI（Network Node Interface）information of gateway network elements from the local connection connect to the elements,and join in the NNI queue,until all the interfaces are found.Then,pull a interface object from the NNI queue and find the interface of the adjacent element *A* ,join in the corresponding interface queue of *A*, and traverse the NNI interface of *A* to find adjacent network element *B* ,then iterate,similar to the thought of Depth - First walk of the tree-structure,until loop through all the network elements for NNI interface informations to discover the entire EPON network topology.

Realization of Topology Display

Considering the scale of EPON network and features,the overall layout is designed as relative layout, which is the hierarchical display;while absolute layout is taken within every subnet,meaning that change the actual information of the node and link locations into the form of the coordinate(x,y)corresponds to the origin (0,0)of the topological interface,also supports the user to manually adjust the layout and save the adjusted results.

Improvements to Memory Object

Split API property supplied by hardware provider into smaller objects,and distinguish important properties and general properties according to the actual needs of customers,meanwhile

the content of the table of the database is modified.The only one property of the main object is the main key corresponds to the primary table,and other properties are scattered in more than one table as the foreign key.

The Result of the Test

All of the three types of OLT devoices are found by network elementdiscovery,but before that domain, subnet, and groups should be created,so that network elements in a certain category can be distinguished. After improvements to the memory object,redundant data that occupied the memory space is reduced significantly.Table 2 shows the result of in a certain test environment(12 sets of network element equipment ,26 paths between the network elements).

Table 2 Result of test

business situation	network element discovery (before the improvements)			network element discovery(after the improvements)		
	number of equipments	number of paths	elapsed time (seconds)	number of equipments	number of paths	elapsed time (seconds)
null	12	26	3.8	12	26	3.0
1000 business	12	26	5.6	12	26	4.3
3000 business	12	26	7.8	12	26	6.0

Summary

This paper focus on algorithm of topology discovery,including architecture, functionality, structure, memory objects, topology discovery and topology display.But inadequacies remain,system should be expended to perform topology discovery of new type of equipment.Also,the system structure should develop from c/s to b/s .

The research and application based on competitive scheduling mechanism in Mine Based Wireless Mesh Networks

Qi Shen

School of Software Engineering Beijing University of Technology, Beijing, China

shenq@bjtu.edu.cn

Keywords: self-organizing network; scheduling algorithm; media access control

Abstract.This paper analyzes the current MAC layer protocol for wireless sensor networks based scheduling, according to the transmission of mine environment signal needs, around the traditional CSMA / CA technology, a scheduling algorithm is proposed adjustment factor based on the contention window to more effectively avoid data collisions at the MAC layer transmission process. In order to ensure more equitable sharing of all nodes in wireless link bandwidth. Simulation results show that the algorithm can effectively improve the information in the MAC layer transmission reliability.

1.Introduction

Wireless Mesh network can build multipoint to multipoint network architecture, RFID technology is generally responsible for the deployment of information nodes in the network, While the location aware system can be achieved by using ZigBee, the integration of these three can build an omnipresent information network environment. Based on the mine wireless mesh network architecture, Use of RFID the non-contact automatic identification technology, transmission a frequency of the signal, after treatment and then transmitted to the location aware systems, precise positioning can be achieved in real time, then determine the specific location information. ZigBee is based on the IEEE802.15.4,this is based on the IEEE wireless networking standard security technology, is also an IEEE standard for wireless personal area network working group, has the most power saving, the advantages of maximum network node number and minimum cost, designed for low-cost, low-power multi-node network, this fully satisfy the requirements of the Mine Mesh Networks, so the fusion of ZigBee technology and RFID technology, can greatly improve the performance of mine Mesh network.

ZigBee is based on the IEEE802.15.4,while 802.15.4 MAC layer is based on the 802.11 wireless LAN standard, a good MAC layer protocol for network traffic, capacity and stability has a direct impact. Mine environmental transmission of signals need excellent anti-interference ability, although the 802.15.4 MAC layer protocol combines CSMA / CA (Carrier listening Multiple Access) anti-jamming technology, but the application environment in the mine can not achieve satisfactory results.

2.MAC layer protocol

The MAC layer protocol for wireless Mesh networks need to make the appropriate changes according to the characteristics of wireless Mesh network. Despite the presence of a centralized entity (gateway), however, the gateway will not be able to coordinate the MAC layer node a few hops away. An important problem in wireless Mesh MAC is how to efficiently use multiple physical channels. In the infinite Mesh network, all the access nodes compete for the use of a wireless LAN link resources. Therefore, the need for a queue scheduling mechanism to ensure fairness of all nodes to access resources. Therefore, the need for a queue scheduling mechanism to ensure fairness of all nodes to access resources.

2.1.MAC layer overview

MAC layer is mainly responsible for dealing with tasks of access the physical channel, it provides 2 kinds of services: the MAC layer data transmission service and MAC management service.MAC layer data transmission services primarily to ensure that the correct MAC protocol to send and receive data at the physical layer, while MAC layer management services is responsible for the management and function achieve of MAC layer, including channel scan and access, association of network and exit, synchronization between devices, transport management and other things. Where the MAC layer during data transmission, since the physical transmission media is information sharing, each slot can have only one physical channel occupied physical signal to transmission channel, therefore, the data to be transmitted during the access physical channel will collisions. Although the 802.15.4 MAC layer protocol combines CSMA / CA (Carrier listening Multiple Access) anti-jamming technology, to avoid a collision when data is transmitted.MAC IEEE802.n provides two kinds of media access control mechanism, they are called Distributed Coordination Function(DCF， Distributed Coordination Function)And Point Coordination Function(PCF，Point Coordination Function).

PCF also called uncondensed services. Specifically, PCF uses AP (Access Point) access algorithm in centralized control will send the data right turns to each site, thus avoiding the generation of conflict. On the other hand, DCF is also known as contention Services, that is DCF using CSMA / CA (carrier sense Collision Avoidance) mechanist each node for distributed access method, let each site by the contention channel to get sent right. In Wireless Mesh Networks, the main uses of this competition mechanism, the core algorithm of DCF system is the binary exponential back off algorithm (BEB),to avoid collision between nodes back and forth.

DCF is also the main as a basic control mechanism, is widely used in wireless Mesh networks. However, the core of this algorithm is binary back off algorithm, many drawbacks exist, this paper presents an improved method based on the competition window, to improve the overall performance of the MAC layer.

2.2 The basic scheduling algorithm

In the whole network has many processes responsible for ensuring the efficient operation of network, they are running on different time level, they were: scheduling and buffer management (microseconds), Feedback control (ms), re-negotiation (s), call control - Routing (minutes).

The scheduler acts on each packet, acts as a coordinating role of the minimum strength, its features include: Ensure that different types of services with different QoS, determine whether the network is fair, and allocate bandwidth to different business, to ensure delay, packet loss, to restrictions delay jitter .

Reasonable scheduling algorithm is to determine the key factors that network quality of service. One of the most common algorithms include queue scheduling algorithms including FIFO queue (FIFO), Round Robin (Round Robin), and PF (Proportional Fair) algorithm.

FIFO queue is the most simple scheduling algorithm based on priority. Time stamp packet data in the FIFO queue is the packet arrival time. FIFO queue provides basic storage forwarding function, is currently the most widely used method, it uses queuing method by default, do not need to configure. Its advantages are simple, low cost; on the other hand, its drawback is unable to provide QoS features and isolation technology, lack of fairness, vulnerable to attack illegal users.

First put forward in the scheduling model in the scheduling model is the Round-Robin model, as shown in Figure 1 the principle of the model.

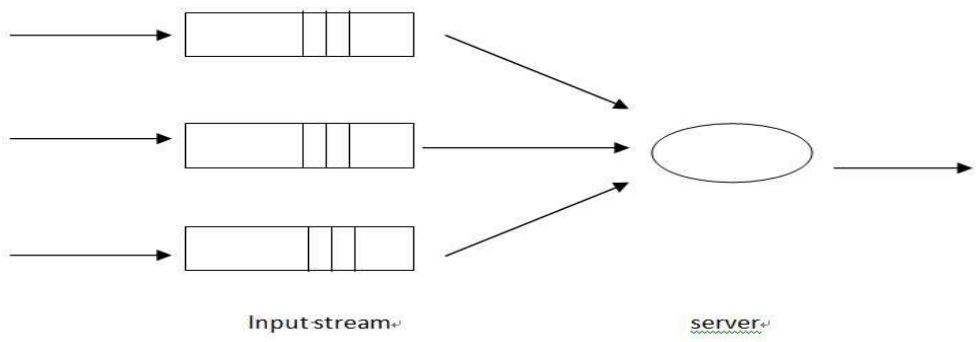

Fig. 1 Robin scheduling model

A scheduler flow to maintain a queue for each service, Round-Robin algorithm sent out a packet from every business stream in the scheduling architecture, Until an empty traffic before transferring to the next traffic. However, when the packet size in the service stream is variable, this method does not provide a fair allocation of bandwidth, Traffic larger obviously get more bandwidth than the small one. Therefore, researchers have proposed an algorithm called Bit-By-Bit Round Robin's. The algorithm assumes that a packet service stream can be divided into a one bit to transmit, the scheduler still turn each of a traffic service. In this model, we assume that $R(t)$ indicates the number of polling algorithm , $N_{ac}(t)$ indicates the number of business activities, business activities in the queue means a bit of business to be transferred. Suppose μ is a scheduler exit rate, there is the following formula:

$$\frac{\partial R}{\partial t} = \frac{\mu}{N_{ac}(t)} \tag{1}$$

After integrating both sides of the equation, we can get

$$R = \int \frac{\mu}{N_{ac}(t)} dt \tag{2}$$

It represents the more the business activities, the slower growth in the number of rounds.

Holzman presents a classical proportional fairness algorithm(PF) in reference [3],the expression of PF algorithm used in the scheduling judgment:

$$i = \arg\max \frac{R_i(t)}{T_i(t)} \tag{3}$$

Wherein, $R_i(t)$ is the transmission rate of user i in timeslot t.the throughput$T_i(t)$ of user i (Equation 3) has been update in each slot by the exponential smoothing process:

$$T_i(t) = \left(1 - \frac{1}{t_c}\right) T_i(t-1) + \frac{1}{t_c} R_i(t) \cdot I(t) \tag{4}$$

Wherein, $I(t)$ is the indicator function: If the user i get scheduled at time slot t, $I(t) = 1$,otherwise, $I(t) = 0$. Where the time constant of the smoothing process (unit: slot), the specific values decided by the maximum access delay of the user i can be tolerated, t values usually between 100 to 1000. As can be seen from Equation 3 and 4,the scheduling verdict of PF algorithm is determined by the transmission rate and throughput: When the transmission rate of a

user is larger or throughput smaller, it can be easier to obtain a certain scheduling. Furthermore, since a low value t_c can speed up the update speed of the $T_i(t)$, when a user does not get any more service at timeslots continuous, the smaller $T_i(t)$ can make $T_i(t)$ decrease rapidly, Allowing the chance of users access to scheduling increased greatly, this shows that the PF algorithm can provide some small-scale service time guarantee for users.

2.3 Packet scheduling algorithm based contention window

In this paper, start with the single FIFO queue mechanism used in the MAC layer protocol. Around the MAC layer protocol. We study the packet scheduling algorithm based on the contention window, and we add a control factor based on the original algorithm, making a better scheduling effect. Assuming all nodes are within transmission range of the other node[4].MAC layer queuing model shown in Figure 2.

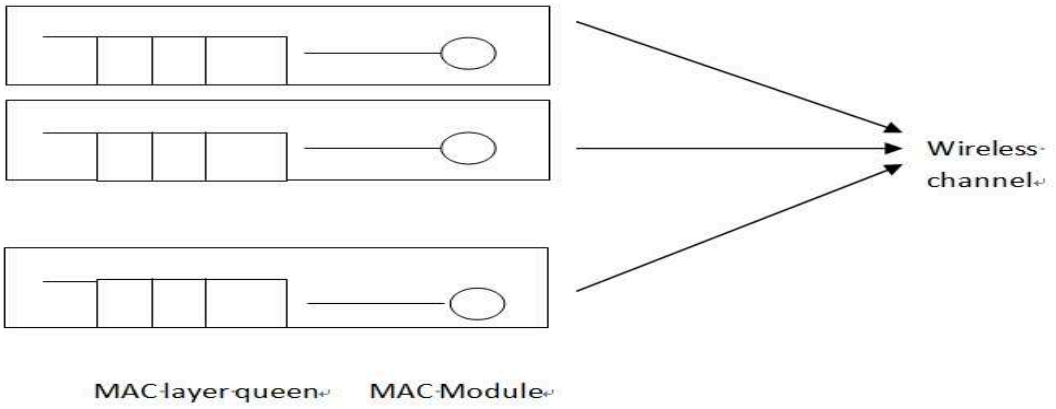

Fig. 2 MAC layer queuing model

The following describes directly a packet scheduling algorithm based on the competition of the window: The main difference between this algorithm and IEEE 802.11 DCF is that collision resolution algorithm. In addition to the original agreement back off window has added a new competitive window. Thus, competition between nodes is divided into two stages: When the channel is free, the node sending data goes into the first back off stage. Only the nodes completed the first phase of retreat can goes into the second stage. Same as IEEE 802.11,The second back off stage can only start after the data channel is idle. However, after the competition of first back off stage, there will be only part of the node enters the second stage back off. This will reduce the probability of collision between the nodes and the new range of back off window can be relatively small.

From the above analysis we can see the advantages of contention window algorithm is significantly reduce the collision probability in the new stage. Its downside is that when there are small number of nodes, to a certain extent, increased channel idle time.

A retreat from the first stage of the competition node using the back off counter BC_1 competition began retreating to solve the problem of collisions.

If BC_1 is nonzero, then BC_1 will randomly select from within $[0, CW_1]$, CW_1 is the contention window of the first stage. If the channel is idle, BC_1 minus 1 per time slot. when channel is idle, and BC_1 minus to 0,The winners advance to the next stage.

BC_2 is the second stage of the competition back off counter, it randomly select from within $[0, CW_2]$, CW_2 is the contention window of this stage. BC_2 minus 1 per time slot. The first one reduced to 0 nodes start access channel, others stops back off activities.

If a node sending the packet successfully, it returns the first back off stage. In fact the channel collision happen in the second stage, and when a collision occurs at this phase, CW_1 and CW_2 are exponentially increased power 2,until reach their maximum.

CW_1 select from within $[CW_{1,\min}, CW_{1,\max}]$, CW_2 select from within $[CW_{2,\min}, CW_{2,\max}]$.After the successful transmission of data packets, the competition window will return to their minimum, waiting for the next delivery.

3.Regulators scheduling algorithm based on the contention window

In order to effectively solve problems related to performance caused retracted, MILD back off algorithm combined with traditional algorithms and different performance in achieving fairness. Inspired by the MILD, This paper attempts to modify the CW reduce and growth in back off algorithm and rules to improve the algorithm. Second window back off counter is no longer a process for reducing the integer 1,But a characteristic combination MILD algorithm-back off diminishing negative exponent form, Corresponds to the inverse of the original protocol retracted, this approach can effectively inhibit the fairness issue, but also to the network quickly tracking system frequency conflicts.

3.1 scheduling algorithm based on the Reusable contention window

A brief description of the principle of improvement: Retracting the first stage described as above. When retracted into the second stage, Back off counter BC_2 value from $[CW_{2,\min}, CW_{2,\max}]$,after a node clashes, contention window CW_2 is multiplied by two, waiting to be sent back. If the conflict continues to occur, repeat until get the window limit values. If the channel is idle, then reduced according to the following formula until reduced to 0;In this algorithm, CW mode are still rising contention window-based approach, using the drop method corresponds to the inverse of the rising process in the second back off stage. CW Rise way based on the contention window, drop method using the inverse process of the process corresponds to rise in the second stage of retraction. It is not difficult to get to this conclusion: If the BC_2 is too small, the possibility of the collision between the entering node of the evacuation second stage will increase. There appears a phenomenon a node can not be serviced. So, BC_2 value from $[CW_{2,\min}, CW_{2,\max}]$;Thus, BC_2 Smooth fast diminishing, can reduce system latency also reduce the network system to track the frequency of conflict, "the response speed."

Therefore, according to the above analysis, we adopt the following strategy.

$$BC_{2,new} = \left\lceil BC_{2,old} \cdot \left(1 - \frac{1}{\log(BC_{2,old})}\right)\right\rceil \tag{5}$$

$\lceil \bullet \rceil$ Said the rounding operation, $BC_{2,new}$ represents BC_2 after the update. $BC_{2,old}$ represents the original BC_2.On the other hand, the multiplicative factor $1/\log(BC_{2,old})$, ensures the drop-off time stationary of the second phase, at the same time, reduced the time BC_2 reduces to 0, thereby increasing the overall response speed.

3.2 Simulation and Analysis of Algorithms

Simulation performance of the algorithm by MATLAB, the window is set as follows: $CW_{1,\min}$ is 31, $CW_{1,\max}$ is 1023, and $CW_{2,\min}$ is 63, $CW_{2,\max}$ is 511, through research the saturation throughput (As the load increases and the system can carry a maximum throughput)to research channel utilization, and assuming that each node always has data waiting to be sent, traffic sources has constant bit rate, and data packet fixed, this paper use 512-byte as sizes of different Data packets, the number of simulation nodes changes from 2 to 64. The following figure shows the throughput comparison of different algorithms.

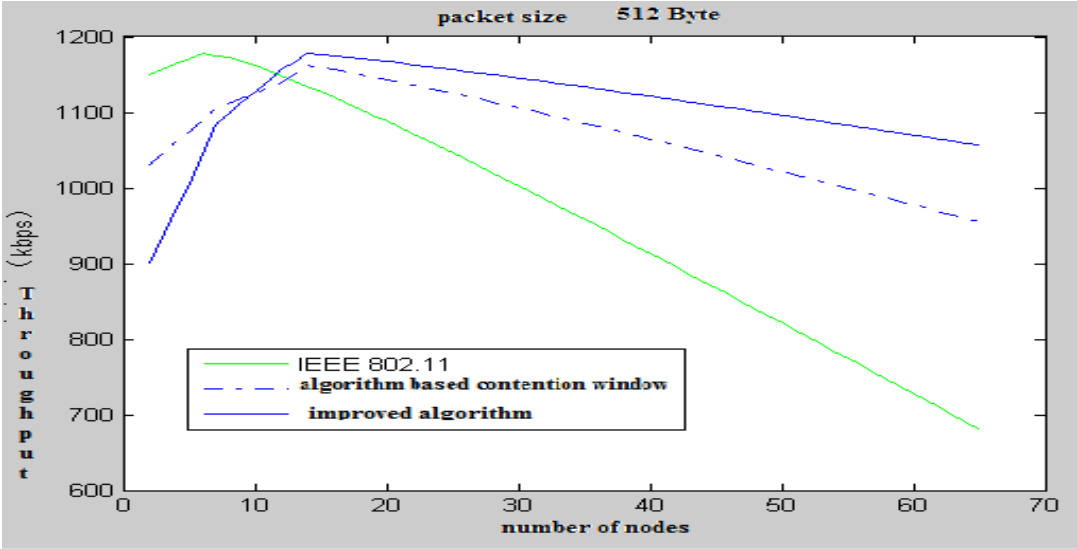

Fig. 3. IEEE802.11 and Comparison of saturation throughput based saturation throughput packet scheduling algorithms

By MATLAB simulation results, we can see, adjustable factor contention window scheduling algorithm based on this article, it can improve anti-jamming capability of wireless Mesh networks, give full play to the advantages of ZigBee technology, provides technical support for the construction of the mine network.

4.Conclusion

On the basis of service and data provided by the MAC layer transmission mechanism and the traditional scheduling algorithm analysis, we propose a new scheduling algorithm to more effectively improve the reliability of data transmission of MAC layer. By adding a new layer of back off window on back off process, you can reasonably control reasonable order what needs simultaneously transmitted data packets need to wait. While since the addition of the back off window, the considerable possibilities of all packets to be sent in the collision new avoidance factor becomes lower, while reducing the probability of collisions occurring again, accelerate the transmission of the data and to ensure the reliability of the MAC layer data.

Study on the Technologies of Operating System Scanning

ZHU Nafei, ZHOU Yue, LOU Li and WANG Wei

National Application Software Testing Labs, Beijing, China

{znf, zhouyue, louli, wangwei}@bsw.net.cn

Keywords: Operating System Scanning, Operating System Fingerprinting, TCP/IP Protocol Stack

Abstract. Operating system (OS) scanning makes it possible to focusing further attacks to known weaknesses of that system. The principle of OS scanning is that different OS vendors may make different implementations for the TCP/IP protocol in their OS products. IP, UDP and TCP as well as application layer protocols are can be used for OS scanning. These methods can be used in active ways sending probes to the targets or passive ways only listening without probes. Totally, whether it used in an active or passive way, the essence for OS scanning is analyzing the characteristics of the packets sent by the targets and matching the characteristics with certain operating system. So, in some cases, we need two or more of these methods together to determine the type of the OS for the target.

1 Introduction

Network scanning can be divided into four steps which are host scanning, port scanning, operating system detection and vulnerability scanning. Each of these scans has its own aim and technology. Host scanning determines whether the target host is alive and port scanning detects the open port on the target host. And then, OS detection and vulnerabilities scanning are conducted based on the results of the port scanning. Host and port scanning have been already related in paper [1]. In this paper, we will analyze the technologies of OS scanning, and then make a comparative study among these 15 scanning methods, especially focusing on the active or passive way it takes. This paper is organized as following: In section 2, we introduce the purpose and principle of OS scanning; in section 3, scanning technologies including 15 methods are analyzed; in section 4, we make comparisons among these scanning methods; we conclude this paper in section 6.

2 Purpose and Principle of OS Scanning

Operating system scanning is handy for determining if the attacking target is a Windows, Linux, or other type of machine. Knowing the operating system of the target will save time by focusing attacks to known weaknesses of that system. There is no use in exploring exploits for a Linux machine if the target is running Windows [2].

Operating system scanning has two purposes: obtaining the OS information of the target host and the program information of the services. The principle of OS scanning is that different OS vendors may make different implementations for the TCP/IP protocol in their OS products. Thus, these differences can be used to identify different systems.

3 Technologies of OS Scanning

Totally, the technologies of operating system scanning can be classified as three types, which are banner information detection, HTTP response analysis and TCP/IP stack fingerprinting identification.

3.1Banner Information Detection

Connecting to certain open ports of the host, these service programs, such as FTP, Telnet and Sendmail, often show their Banners, the basic information of these applications, so we can directly get the type of the OS, version number and so on. This may be the simplest method for OS scanning.

3.2 HTTP Response Analysis

After establishing the HTTP connection to the target host, its OS information can be analyzed from the target host responses.

3.3 TCP/IP Stack Fingerprinting Identification

TCP/IP stack fingerprinting is the process of determining the identity of a remote host's operating system by analyzing packets from that host [3]. This process is to scan TCP/IP stacks, shown in Fig.1, efficiently by quickly matching query results against a database of known operating systems. Though the TCP/IP is a standard for network communication, certain parameters within it are left up to the implementation. Different operating systems, even different versions of the same operating system, set different defaults for these values. By collecting and examining these values, one may differentiate among various operating systems, and implementations of TCP/IP.

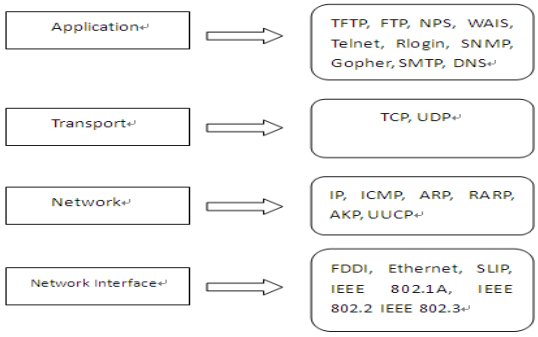

Fig. 1 TCP/IP Protocol Stack

(1) Acknowledge Number

Different OS handles the ACK number in different ways. Sending a FIN/PSH/URG packet to a close the TCP port, most OS will set the ACK number of the response packet (RST packet) as the initial number of the sending packet, while Windows and some printers will send a RST packet with ACK number set to be the initial sequence number added 1.

(2)Type of Service

For ICMP port unreachable message, the TOS (type of service) value of this message package is different among different operating systems. Most operating systems will set the TOS to be 0x0000, while the Linux sets it to be 0xc0.

(3) ICMP Address Mask Request

For ICMP address mask request, only a few operating systems will send back the corresponding responses. These systems include OpenVMS, Windows 95/98/98 SE/ME, Windows NT below 4 SP, and SUN Solaris machines. Furthermore, in the reply to fragment ICMP address mask request, sun system is not the same to others, so we can identify the SUN.

(4) Responding to the FIN

Sending a FIN packet, only the FIN flag set to 1, to an open port, Linux will reply nothing, while other systems, such as MS Windows, CISCO and HP/UX, will responds with a RESET packet.

(5) Fake SYN Packet

Setting an undefined TCP flag in the TCP head of the SYN packet is referred as the fake SYN packet. Sending such a fake packet to the target system, some operating systems, such as Linux machine before 2.0.35, will keep this flag in the responses, while some operating systems will not. Also, some systems will reset the connection when receive this packet.

(6) Initial Sequence Number

Different systems choose TCP ISN (Initial Sequence Number) in different ways [4]. Some UNIX systems adopt the traditional method of 64k progressive increase. New Solaris, IRIX, FreeBSD, Digital UNIX and Cray systems adopt the method of random increment. Linux 2.0, OpenVMS and AIX system use true random methods. Windows system adopts a kind of time correlation model. Some systems use the constant, such as 3com hub uses 0x803, Apple LaserWriter printer uses 0XC7001, etc.

(7) ICMP Error Message
RFC 1812 specifies the sending speed of the ICMP error message. Linux sets the maximum unreachable message (type 3) speed to 80 per 4 seconds. So we can detect the OS by sending a large number of packages to the high UDP ports, and then calculate the number of the unreachable message. But this method need to send a lot of package which is time cost and not credible for the package may be lost in the communication.
(8) ICMP Message Quoting
RFC specifies that ICMP error messages can quote part of the original message caused the error. For the port unreachable messages, the reply packages of the most systems quote the IP request header plus 8 bytes. Solaris quotes a bit more and Linux even much more. Some systems, such as FreeBSD, OpenBSD, ULTRIX, will change the head of the message causing the error and then send it back to the source. This method is still effective to identify Linux and Solaris, even when the target host does not open any port.
(9) Maximum Segment Size
Maximum Segment Size (MSS) represents the maximum package length in a TCP connection, and it is controlled by the initial socket by negotiation during the TCP connection establishment [5]. Different operating systems have different MSS values, and their responses to different MSS values are not the same during the negotiation in the connection establishment. If send a small MSS value to Linux host, it will generally send back this value unchanged, while some other systems will return different values.
(10) SYN Flood Limitation
Different operating systems deal with the SYN flood in different manners [6]. Many systems can only deal with 8 SYN packets at the same time, and they will refuse new TCP connection requests if they are handling more than 8 SYN packets.
(11) TCP Initial Window Size
It is more reliable to estimate the OS by analyzing the initial window, because many operating systems are different in the initial window size. Such as AIX set the initial window size to be 0x3f25, while Windows NT5, OpenBSD, FreeBSD x402E set a value of 0. Analyzing the initial window size in the response packet is another way to estimate the type of the operating system.
(12) DF Flag
In order to improve performance, certain systems set the DF (Don't Fragment) flag "on" when sending the data package, so we can estimate on the type of operating systems according to this.
(13) Time to Live
Each operating system has its own constant TTL (Time to Live) value, such as TTL of LINUX Kernel 2.2.x&2.4.x is 64 , while TTL of FreeBSD 4.1,4.0,3.4 as well as Sun Solaris 2.5.1,2.6,2.7,2.8 is 255, at the same time, TTL of Windows NT and Windows 2000 is 128. So, we can make estimation about the type of operating systems according to this characteristic.

4 Comparisons of the Methods

Here, we make comparisons among all these 15 scanning methods related above to show whether it is an active or passive scanning. Active scanning sends probe packet to the target and estimate the type of the OS by comparing its replies with the operating system database. Passive scanning sniffs the target communication packet instead of sending probe packets to the target. It estimates the type of operating system by analyzing the grasped packet in the same way as the active scanning analyzes the replies. The results are shown in Table 1. In this table, the columns represent the 13 scanning methods and the name of every scanning is demonstrated by the main part of its original name to save space. The rows demonstrate the active and passive ways. If the scanning method can be implemented in such way, we label a " √ " in the corresponding blank.

From this table, we can see that (1) The methods can be used in a passive way are can be used in an active way. (2) ICMP packets are mostly used for active ways, for they are requests and replies in

couples. (3) TCP and UDP protocols can be used by active ways and passive ways. (4) Application layer protocols such Telnet or HTTP are used for active ways. Totally, whether it used in an active or passive way, the essence for OS scanning is analyzing the characteristics of the packets sends by the targets and matching the characteristics with certain operating systems. So, in some cases, we need two or more of these methods together to determine the type of the OS for the target.

Table 1 Comparisons among Scanning Methods

	Banner	HTTP	ACK	TOS	ICMP17	FIN	SYN	ISN
Active	√	√	√	√	√	√	√	√
Passive			√	√				
	ICMP 3	ICMP Quoting	MSS	SYN Flood	Window Size	DF	TTL	
Active	√	√	√	√	√	√	√	
Passive					√	√	√	

5 Conclusion

Operating system scanning is handy for determining if the attacking target is a Windows, Linux, or other type of machine. Knowing the operating system of the target will save time by focusing attacks to known weaknesses of that system. The principle of OS scanning is that different OS vendors may make different implementations for the TCP/IP protocol in their OS products. IP, UDP and TCP as well as application layer protocols are can be used for OS scanning. These methods can be used in active ways sending probes to the targets or passive ways only listening without probes. Totally, whether it used in an active or passive way, the essence for OS scanning is analyzing the characteristics of the packets sent by the targets and matching the characteristics with certain operating system. So, in some cases, we need two or more of these methods together to determine the type of the OS for the target.

Keywords: 6LoWPAN, border router, wireless sensor networks, IPv6

Abstract. With the rapid development of Internet of things, IPv6 has been introduced into wireless sensor networks and widely used in many areas. It is significant to develop routing devices to connect wireless sensor networks and the Internet based on IPv6 technology. In this paper, we present a 6LoWPAN (IPv6 over Low power Wireless Personal Area Networks) border router scheme. The hardware design and software design are discussed and the experimental results demonstrate the feasibility of the router scheme. By using the proposed border router, the network can achieve end-to-end communications between 6LoWPAN nodes and IPv6 hosts in a universal method.

Introduction

In recent years, with the rise of Internet of things and Wireless Personal Area Networks (WPAN), an important research focus is to combine WPAN with the next generation Internet technology-IPv6. Wireless sensor network is widely used in areas such as smart home, industrial inspection and so on for its short-range and low-power characteristics. The IPv6 technology has huge address space and simplified packet header format, which makes low-speed wireless personal area network nodes connect to the Internet and has its own IP address. As 6LoWPAN utilizes standard IPv6 protocol in the network layer [1], 6LoWPAN nodes can be connected with public IPv6 network hosts through 6LoWPAN (IPv6 over Low power Wireless Personal Area Networks) border router, which can achieve the end-to-end communications.

In this paper, we present a border router aiming to collect data of wireless sensor network and transmit data to public IPv6 hosts if the destination address is known. The function of configuration and management of wireless sensor networks is another aim of 6LoWPAN border router in order to satisfy different application requirements. And users can access the subnet nodes to get information locally or remotely.

System Architecture

6LoWPAN provides a kind of simplified adaptation layer which works between network layer and data link layer. The adaptation layer is used to encapsulate and compress the IPv6 header to allow IPv6 packets to be sent and received over IEEE 802.15.4 based networks. When the border router receives anIPv6 packet, it disassembles the IPv6 packet，compacts it into a shorter 6LoWPAN header and forwards this packet to a sensor node in wireless sensor network. When the border router receives a 6LoWPAN packet from wireless sensor network, it decompresses 6LoWPAN header to full IPv6 header and forwards this packet to IPv6 Internet [2, 3].

The border router presented in the paper consists of two parts, one is a sink node as a gateway and the other is a Linux host. The gateway is used to receive sensor data which is sent periodically by wireless sensor network nodes [4]. When the gateway receives the data sent to remote public IPv6 host, the gateway deliver the data to the Linux host via a SLIP interface. Then the Linux host handles these packets and decides to forward or to discard the packets.

The convergent gateway and Linux host can be connected with any communicated interface [5]. However, we use serial interface in this paper. If Linux host is connected to Internet, then wireless sensor network nodes are able to communicate with IPv6 hosts by end-to-end, which can greatly reduce network complexity and improve communication efficiency. The architecture of 6LoWPAN border router is shown as Fig. 1.

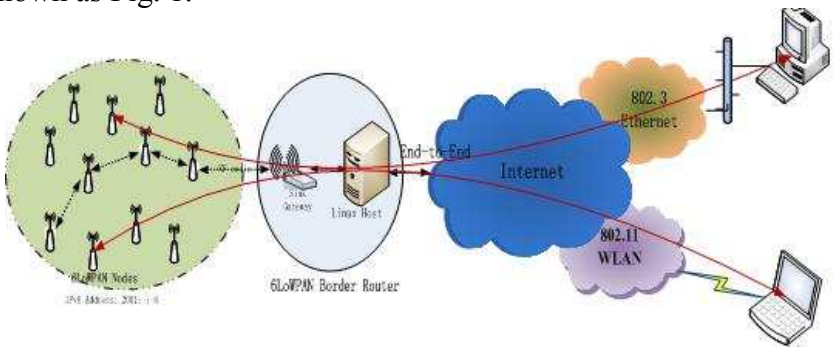

Fig.1 Architecture of 6LoWPAN border router

Design and Implementation

In this section, the detail of design and implementation of the 6LoWPAN border router is discussed.

Hardware Design. It is known from the system design scheme above that the 6LoWPAN border router presented in this paper is made up of a convergent gateway and a Linux host. The hardware design is mainly for the convergent gateway. Considering the convenience and generality of connecting gateway with Linux host, hardware design should be simplified as much as possible to minimize volume. The core part solution is a STM32 chip plus a 2.4 GHz RF module. Other modules include power supply circuit design, debug circuit design and interface circuit design, etc. The architecture of hardware design is shown as Fig.2.

We use STM32F103RB as master control chip for its low price and rich resources, and UZ2400 as wireless RF module of 6LoWPAN border router. UZ2400 is a kind of standard solution conformed to the IEEE 802.15.4 to meet the needs of low cost and low power wireless applications. The master controller connects the RF module by SPI bus.

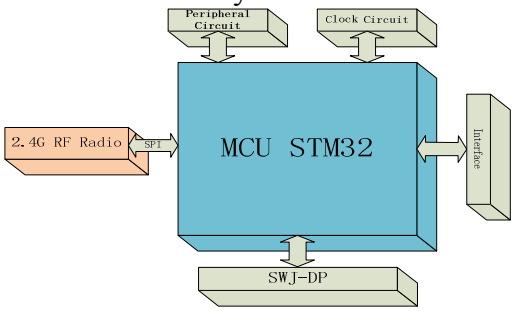

Fig.2 Hardware design of border router

Software Design. The software design of protocol stack is based on Contiki 2.6 operation system. Making full use of existing resources on Contiki, we can improve development effectively. Architecture of protocol stack is shown as Fig.3.

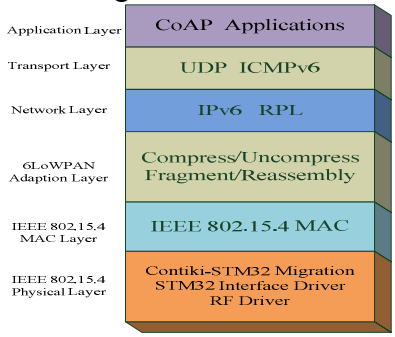

Fig.3 Architecture of protocol stack

There are several mainly sub-modules have to be designed in protocol stack, and they are described as follow.

a) First of all, we use STM32 chip as border router microcontroller. Since the ordinary development environment of this chip is IAR or Keil, we must transplant Contiki operation system to STM32 microcontroller by IAR in order to meet our development habits.

b) Secondly, we use UZ2400 as border router RF module. SinceUZ2400 radio is not supported by Contiki, we should develop the driver in Contiki using STM32 as master controller. We use SPI interface to control RF radio and to send and receive data normally.

c) And then, we use serial interface to communicate with upper computer. So the serial interface of STM32 must be driven in Contiki OS.

d) Finally, we use RPL and CoAP in protocol stack of border router. RPL and CoAP are supported by Contiki 2.6, but how to use it in border router is an actual problem. We integrate CoAP in the application layer in order to make remote hosts access the wireless sensor networks by border router. RPL is used as routing protocol which has the ability to form network and forward packets automatically.

There are two parts of tasks have to be done in 6LoWPAN border router software development. One is protocol stack designed in the sink node for wireless sensor network, and the other is the design and implantation of daemon in Linux host. 6LoWPAN protocol stack running on the sink node, it can compute the data of wireless sensor network and then judge to forward, route or discard them. However, the daemon of Linux host is made for complete the task of driving the sink gateway and forwarding data.

1) Design and Implementation of Protocol Stack. Nodes communicate with each other by RPL protocol in the subnet of wireless sensor networks. So the implementation and use of RPL is very important to the wireless sensor network subnets. RPL is a Distance Vector IPv6 routing protocol for LLNs that specifies how to build a Destination Oriented Directed Acyclic Graph (DODAG) using an objective function and a set of metrics/constraints. The objective function operates on a combination of metrics and constraints to compute the ‘best’ path. There could be several objective functions in operation on the same node and the mesh network because deployments vary greatly with different objectives.

The core function of sink node of 6LoWPAN is to process the received data when it is work as a convergent gateway. The hardware, Contiki operation system and protocol stack need to be initialized when equipment powers on, and then the sink node begin to form and configure a wireless sensor network, finally it is able to receive data of sensor nodes. The convergence gateway can receive data via RF or slip interface. When the data is coming from RF, we analysis the packets step by step according to protocol stack and decide how to deal with them, received, forwarded or discard. When the data is received from SLIP interface, we must judge which type the data is, if command packet is coming, we do what the command required. However, if the packet is the common IPv6 packet that sends to the remote host, then the border router will forwards it according to its destination address.

2) Background Program Design. We must design background program in Linux in order to realize the function of IP routing of 6LoWPAN border router and driving the sink gateway in Linux operation system. The background program Parsing packets and decide how to deal with these packets, so it looks like a transport channel. Daemons are virtually seen as a network interface by Linux operation system via the sink node. So you don’t have to consider how to realize the wireless sensor network sink gateway, just routing, forwarding and dealing with the packets as it should be done. We can implement it by global ways as shown in Fig.4.

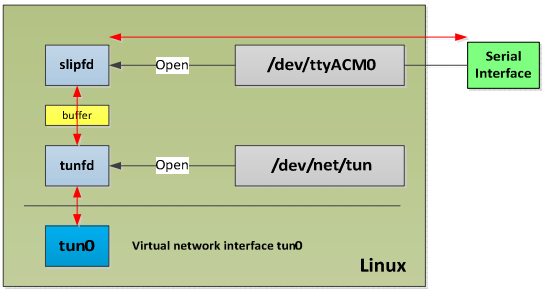

Fig.4 Background program of Linux host

The background program begins to initialize the corresponding interface and network socket when we start it. The daemon must keep listening on multiple interfaces (file descriptor) at the same time, so we can achieve the monitoring on more than one interface by calling select function which is offered by Linux operation system.

Experiment and Evaluation

In order to validate the function of 6LoWPAN border router presented in this paper, we deploy a wireless sensor network on a scale of twenty nodes. Each node reports environmental data once a minute, and then the sink node decides how to deal with these packets when it receives the data. At the same time, we use ping command in the IPv6 host of external network to test the connectivity with 6LoWPAN subnet nodes. As the ping command is an ICMP message sent from the network layer, border router will be routed to forward it when received. If the ping command test passed, we can prove the border router works properly. The test topology is show as Fig.5.

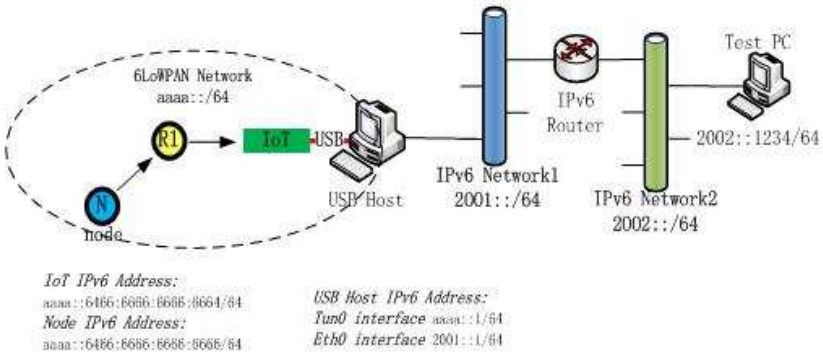

Fig.5 The test topology of 6LoWPAN border router

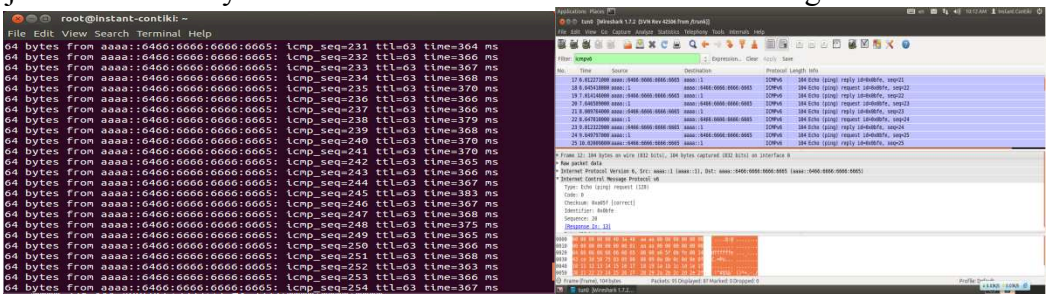
The network prefix is configured as aaaa::/64, the convergence gateway and 6LoWPAN subnet nodes generate its own IPv6 address according to this prefix , for example, the IPv6 address of one node is aaaa::6466:666:666:666/64. We set the IPv6 address of the Linux host's USB virtual interface aaaa::1/64. Moreover, hosts connect to the Internet by Ethernet. And these two IPv6 networks join each other by IPv6 routers. The test results are show as Fig.6.

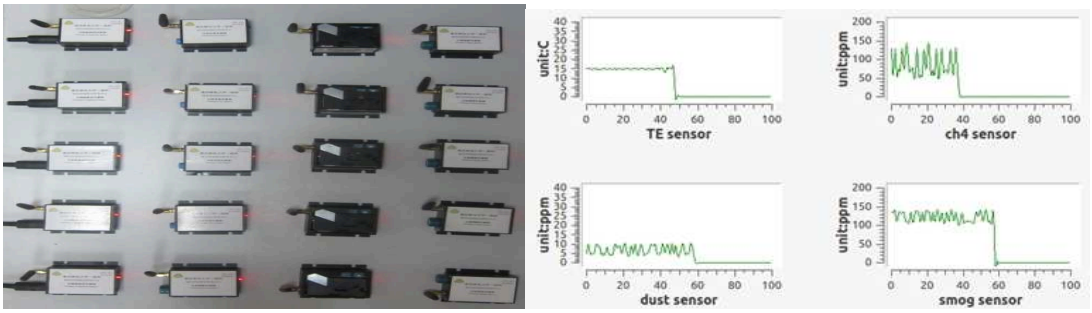


(a) Ping command test (b) Sniffer analysis

Fig.6 6LoWPAN border router Ping command test

We use sniffer in Linux such as Wireshark to analysis the packets received by Linux host. The Wireshark in Linux host can capture these packets. Ping command is an ICMP packet which is sent and forwarded in network. If we use ping command, it will generate request packets firstly, then the

request packets will arrive at the 6LoWPAN border router, since the packets is not sent to border router, then they would be routed and forwarded by border router according to their destination addresses, and the border router will sent the packets to final destination if the network is connected. On the other side, if a terminal node in wireless sensor network receives these request packets, it will reply them, and the response messages will backtrack. According to this experiment, we can test and verify the connectivity of downstream and upstream by 6LoWPAN border router.



(a) Photo of wireless sensor network nodes; (b) Plots of sensor data

Fig.7 6LoWPAN border router packets forwarding test

In Fig.7, we show photos of 6LoWPAN border router test platform. There are twenty sensor nodes in our demonstrate system, and all data are actually measured. Moreover, the plots of sensor data show that the remote IPv6 host has received the sensor data of 6LoWPAN subnet through the forwarding of the border router. There are four kinds of sensor data shown on the plot which are arranged by time sequence. According to the result, we can prove that the 6LoWPAN border router enables interconnect between wireless sensor network and extern IPv6 network effectively.

Conclusion

This paper developed a prototype of 6LoWPAN border router aiming at seamlessly connecting 6LoWPAN subnet to the public IPv6 networks. The border router consists of a wireless sensor network convergence gateway and a Linux host. It could route and forward the packets between the 6LoWPAN nodes and any IPv6 host with end-to-end communications.

Keywords: Uyghur, handwritten character, stroke, on-line collection

Abstract. Data collection is the first step in handwritten character recognition systems, and the data quality collected effects the whole systems efficiency. As the necessary subsystem of on-line handwritten character/word recognition system, a Uyghur handwritten character collection system is designed and implemented with Visual C++ based on the nature of Uyghur handwriting. Uyghur handwritings is encoded by 8 direction tendency and stored in extension stroke file. And they are collected based on the content of Text Prompt File. From experimental results, it can be concluded that the handwriting collection system indicates its strong validity and efficiency during the collection of Uyghur handwriting.

Introduction

Handwritings has continued to persist as a means of communication and recording information in day to day life even with the introduction of new technologies and design new products [1]. The machine recognition of handwriting has practical significance and successfully applied in reading handwritten notes in a PDA, in document digitization and retrieval, in bank check processing, in postal mail sorting, in pen-based text input, and so on[1,2].

Handwriting data is converted to digital form either by scanning the writing on paper or by writing with special pen on an electronic surface. The two approaches are distinguished as off-line and on-line handwriting separately [1]. In the on-line approach, the two-dimensional coordinates of successive points of the writing as a function of tine are stored in order, i.e., the order of strokes made by the writer is readily available. In the off-line approach, only the completed writing is available as an image.

Early research works for handwriting recognition begin 1960s [3]. Nowadays, the handwriting technologies for English and Chinese character is nearly get mature, and it is being used in practical applications. Studies for on-line and off-line handwriting recognition until 2000 year is summarized in survey paper [1]. Liu et.al [2] evaluated state-of-the-art on line and off line handwritten character recognition methods on the new large scale, unconstrained Chinese handwriting databases CASIA-HWDB and CASIA-OLHWDB. Report [4] present an efficient system that automatically generates prototypes for each word in a lexicon using multiple appearances of each letter. So, research works about handwriting recognition mostly based on English handwriting, Chinese handwriting and Arabic handwriting, but there are a few works for Uyghur handwriting recognition.

Uyghur is the official character of Xinjiang Uyghur Autonomous Region (hereafter: XUAR) in China. Research and development on identification system of Uyghur character plays an important role not only on the improvement of technical level of information processing of Xinjiang ethnic minority, but also on the using Uyghur character, and keep its strong applicability and commonality in XUAR. The features of Uyghur character bring difficulties on Uyghur character identification system, such as scarce abstracted information for its simple structure and little stroke; extremely high similar degree for its many similar subclasses; many printed character and certain typeface is similar to handwritten cursive script; common word size is small etc. Now, Uyghur character identification is

on the research period. There no specific report about realization of on-line Uyghur handwriting collection system, and a Uyghur handwritten character collection system is presented in this paper.

Building of Uyghur Handwritten Characters Model

The Nature of Uyghur Character. Uyghur character used in XUAR in China are all alphabetically writing based on Arabic characters and some Persian characters. Uyghur character is composed of 32 letters, in which 8 vowel letters, and 24 consonant letters. Each Uyghur character has 4 types of different forms, thus, these 32 letters have more than 120 character styles [6], and they are indicated as the following Fig.1.

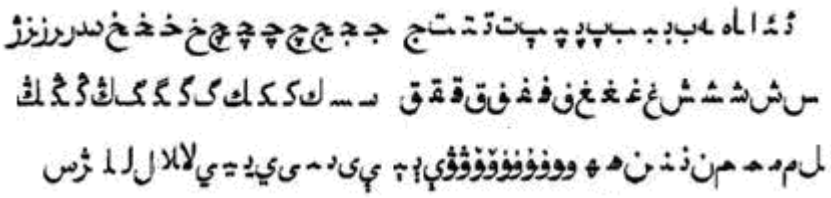

Fig.1 Character set of Uyghur character

Uyghur character is written from right to left, and from left down right for the line progression. There are 4 different writing forms for Uyghur letter: “initial form”, “intermediate form”, “final form”, and “isolated form”. Only the suffix connects with the next character with “initial form”, and initial and suffix connect with adjacent letter to “intermediate form”. Only the initial connects with the above letter with “final form”, and initial and suffix does not connect with adjacent letter to “isolated form”. The selection of writing form in Uyghur character is confirmed as the location of letters in the characters, but Chinese character adopts the same form, and English has two forms, capitalization and small letter.

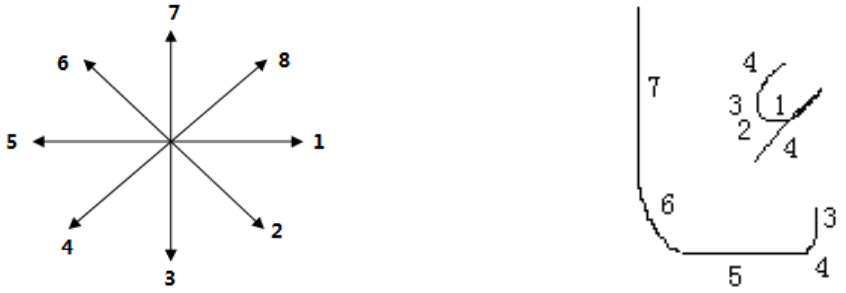
The vocabulary of Uyghur is composed of one or several letters. According to rules of Uyghur writing, these letters will form one or several letter passages by initial and suffix connection. Uyghur letters connect along a horizontal level in writing, which is called base line [5].

Uyhgur letters are not equal in width. This situation happens not only on different letters, but also on the 4 different forms of a certain letter. Even more, a straight line will be adopted to fill in the spaces among the letter to let a line of text distribute uniformly [5]. The features of Uyghur character bring difficulties on character/word identification.

Basically, vocabulary of Uyghur is composed of syllables, which is generally constituted by the combination of vowels and consonants, and vowel is the center of them. It is sure that constitution of syllable and vocabulary is regular in Uyhgur. There is blank among vocabularies, which is basically same as English and Arabic, but different with Chinese.

Usually, there are two types of strokes: one-way stroke and turning stroke. One-way stroke means that the direction of stroke keeps on a certain direction; turning stroke means that the direction of stroke does not keep on a certain direction, it may be two or more direction. Turning stroke includes order stroke, counter stroke and composite stroke. They all exist in Uyghur stroke, of which order stroke appears more

Creation of Uyghur Handwritten Characters Model. The handwriting point and time series date used for online handwriting is relevant with stroke. It is encoded the stroke direction for 8 directions to the Uyghur handwritten characters, refer to as Fig. 2(a). It divides the coordinate plane into 8 areas to encode successively, and the code is called stroke direction code. The effect of handwriting characters encoded as stroke direction referred to as Fig.2 (b) set a Uyghur character “ئا” as an example. The code changed tendency is shown by the direction code series, where “12345678” is just stroke tendency.



(a) 8 direction code (b) Sketch of stroke direction code

Fig. 2 Direction definition of model building of handwritten Uyghur characters

It is Created strike direction code based on the fix of input point as the following formula:

$$K=(Y_{\mu}-Y_{p(t-m)})/(X_{\mu}-X_{p(t-m)}) \quad (1)$$

Where, k is the alternation gradient between two points, and it confirm the relevant direction code according to the gradient. "*m*" refers to the selected coordinate of the *m*th point as calculating the direction code at *t*. The concrete value is confirmed as the collection frequency in actual handwritten input, if the value is too small, it is difficult to overcome the noise caused by tremble and lead to direction code alternation frequently. It is easy to neglect the key point and make false decision, if the value is too big. To meet with the requirement of difficult samples, set *m*=1 in this work, and the noise caused by this will be removed by the filtering treatment hereafter.

File Storage Organization

The collected Uyghur text is stored by the extension stroke file. It contains file header at the beginning, then the texts collected are saved by their order. The descriptor is a character string, and carriage return character is adopted to divide every information is divided by the string '\n', and it is ended with '\0'. The structure of the file is illustrated as the following Fig.3.

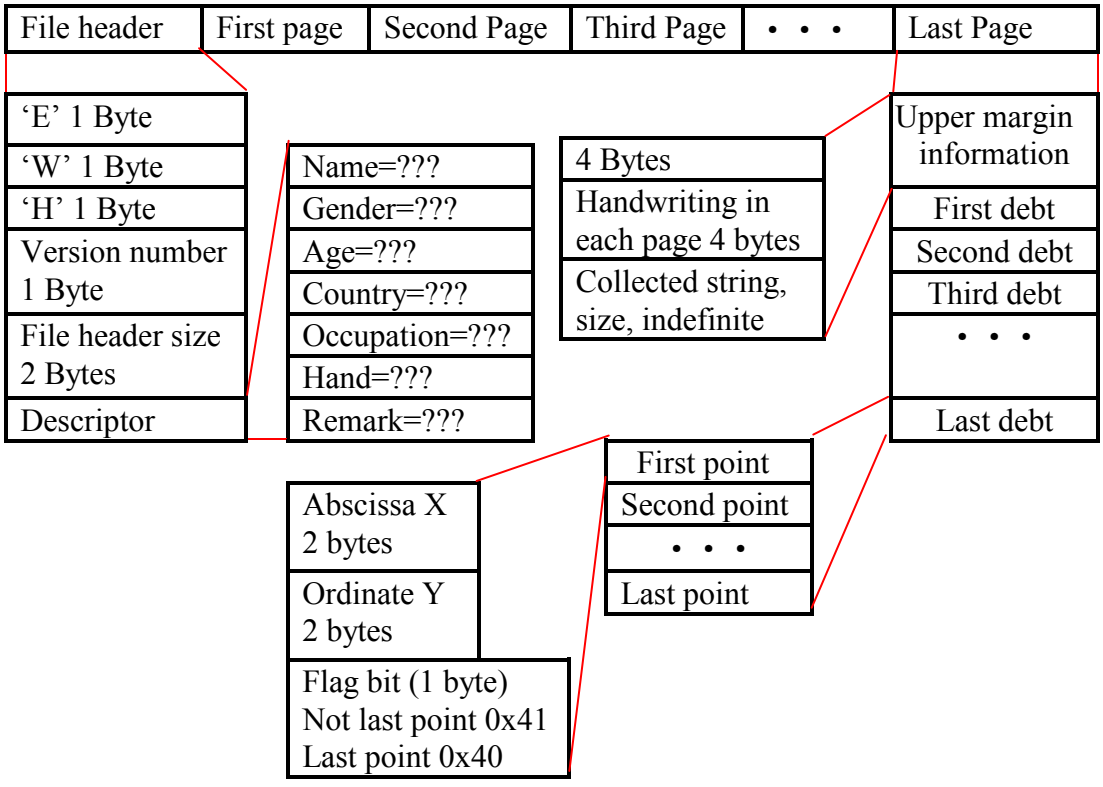


Fig. 3 Structure of extension stroke file

Total numbers of bytes in extension stroke file refer to the byte numbers engaged by the whole page of text, which contains page heading and strokes:

$$N=4+4+N_h+Lc \quad (2)$$

Where N is the total numbers of bytes in the file, N_h is refer to total numbers of bytes for handwriting, and L_c is the character string length. If the character string has no the string '/0' at the end, its length can be obtained by calculation using Equation (2) above. The right side of the coordinate X is positive, and the downside of Y is positive, time refers to the relative time from the beginning of the first point of the first stroke, and the time value of the starting point is 1. The time is invalid if the time value of this point is 0.

System Architecture

The on-line Uyghur handwritten character collection system is composed of Handwriting Collector, Prompt Maker, Text Prompt file and the extension stroke files, which is used for collecting handwritten point and time series data.

Creation of Text Prompt File. The text prompt file is text file, which contains character content need to be collected; its format is described as the following:

[Section###]
Content1
[Section###]
Content2
⋮

Where '###' is digital number increased from 0 as pages. Content1, Content2 are the contents in each page, and it can be characters, punctuation and so on. If the content contains multi-row of text, the collection program will neglect line feed character, and connect them as a whole row. The text prompt file can be created by hand, and produced by Prompt Maker. The flowchart of creating Text Prompt File by using Prompt Maker is presented as the following Fig.4:

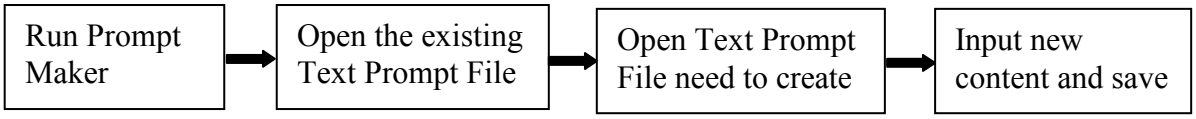

Fig. 4 The flowchart of creating Text Prompt File by using Prompt Maker

A new Text Prompt File is created after clicking "save" (ساقلاش) button on the Prompt Maker. The system asked to save all the Text Prompt Files at the assigned space.

Handwritten Sample Collection. It is collected 1356 Uyghur words, 522 Uyghur simple sentences which each sentence includes 3~7 words by using the implemented handwritten character collection system**.** Handwritten sample collection process is as follows: firstly, the collection program is started, and a new sample dialog is built by double clicking "open" buttons in client area. Then, it is saved the path for handwritten sample after filling in writer information, and the Text Prompt File is opened, and it is entered the sample collection interface. Finally, the Uyghur characters shown in the writing frame, indicated as the collection system frame as Fig.5. The next sample words are presented in the system after clicking the "next page" button. It can be exit the collection system by clicking "finish collecting" when all the samples are collected.

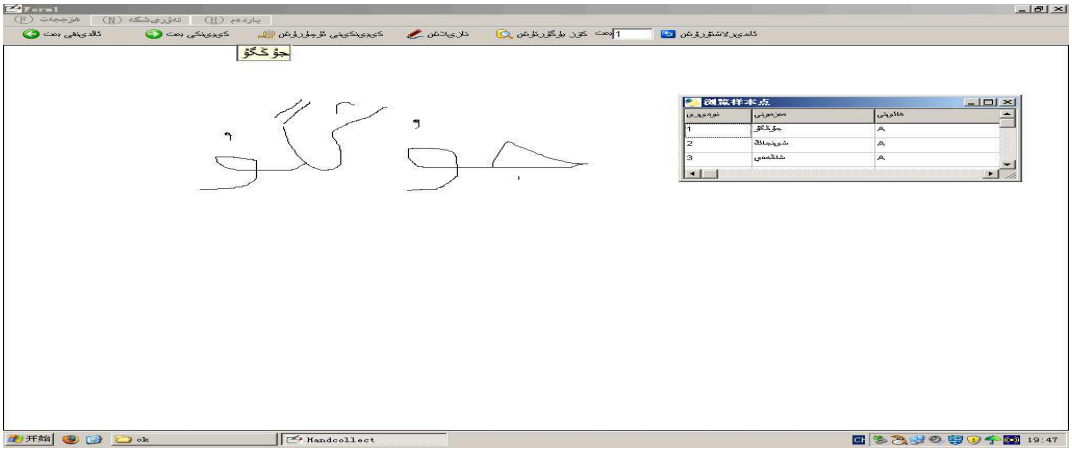

Fig.5 The collection system frame

The collection method used in this system can overcome effects caused by different font style, stroke thickness and font size. However, the twisting on left and right sides and up and down sides of font style shall not change the vector of vertical and horizontal cross feature code. Therefore, this method is very applicable for identifying characters of different size written in different writing habit (left inclined, right inclined, broad or narrow) by different people.

Summary

This paper presents an on-line Uyghur handwritten character collection system. Considering the needs of Uyghur handwritten character/word recognition system (or Uyghur handwritten input system), it is emphasized that the character need to be written from right to the left, and the character size is selected moderate. From experimental results, it can be concluded that the system shows its strong efficiency during the collection of Uyghur handwriting. Besides, the system function is further improved by strengthen editional function, even adding some preprocessing steps for Uyghur handwritten character /word recognition system.

Researching of Project Management Information Systems Based on WBS

Wan-yin Du

Department of Information Management, The Central Institute for Correctional Police, Baoding, China

duwanyin96@126.com

Keywords: Work Breakdown Structure (WBS), Project Management Information Systems, Planning, Control.

Abstract. This paper takes project management information systems as the main object of studying，it applies the theory and means of Project Management Knowledge System，and the specific features of construction project management on the research. It makes detail analysis and deep study to the application of WBS for project management and construction project information classification system.

Introduction

Computers are seen to have the potential to make a significant contribution to the project. The use of information technology has rapidly increased due to its efficiency and effectiveness. In the initial stages of its development, project management information systems main purpose and usage was to improve the efficiency. The value of management information was recognized during its integration stages. Work breakdown structure (WBS) is a one “procedure, concept or technique” utilized for project planning and control.

The use of information technology in project management has rapidly increased due to its efficiency and effectiveness. The project managers are used to spend large amount of time in solving complex allocation problems. Information technologies facilitate the decentralization of work tasks and their coordination in an interactive network of communication in real time.

Project planning is one of the important steps in the process of project management, which impacts many of the steps to follow. The main goal of project planning is to develop the project work plan, considering various aspects. The project work plan could be used to predict the situation of project during its lifecycle, and enables the control of its progress trend.

Project Management Information Systems

The “Management Information Project” is one of the recent methodologies for planning projects. The main concern of this methodology is to offer some special tool s and techniques, to ease the planning of project work breakdown structure and activities. We have assumed that the title of any project could be illustrated by the combination of a” Master Function” (MF), and the “Information Deliverable”. For example the combination of “Construction” and “Information Product ion Complex” which results “Construction of Gas Product ion Complex”, could be considered as the title of a project. According to AMPM, any project “Work Breakdown Structure” (WBS), consists of three different structure s including “Project Control Work Breakdown Structure”, “Functional Work Breakdown Structure” (FWBS), and “Relational Work Breakdown Structure”. As these structures have been used to form the output s of the proposed patterns of neural networks, they have been described in the following sub sections.

PMIS — features, strength and drawbacks

There are numerous different PMIS available on the market that can be used by any industry with respect to the scope of their projects and to their specific necessities. Also, some companies can purchase specifically tailored solutions. Therefore, depending upon the company and the type of projects they will be addressed to, PMIS can vary significantly from one another. However, it is important to note that all projects include several basic elements and that these elements become key requisites of any PMIS:

• Resource allocation, to define teams and individual assignments along with materials;
• Time and Deliverables;
• Assignments;
• Risk management, to deal with uncertainty and control the project flow effectively;
• Monitoring and Quality control.

Owing to the above mentioned considerations, it is possible to individuate several benefits deriving from the adoption and the correct use of PMIS:

•projects can be managed from within integrated and coherent applications;
• tasks and task assignments can be created, updated and tracked in real-time;
• real time completion control gives a justification for the eventual re-scheduling of the project itself;
• individuals are allowed to communicate with one another in real-time. All communications can be logged and tracked from within the software.

At present both small and large firms may adopt project management tools to increase efficiency, productivity and transparency, making the most of a single application which allows them to manage and track their projects. One of the most interesting and valuable aspects is the possibility for the involved managers to act proactively on tasks if resources are behind schedule, increasing the chances that the project will be completed on time and profitably. This is particularly true for companies that run multiple projects at the same time. Additionally, PMIS become essential when teams are made up of people who are dispersed across multiple locations, as it provides them with access to a centralized information database that reflects real-time updates. In brief, they can be effective if any of the WBS statements apply.

Work Breakdown Structure

A work breakdown structure element may be a product, data, service, or any combination thereof. A WBS also provides the necessary framework for detailed cost estimating and control along with providing guidance for schedule development and control.

History

The concept of work breakdown structure developed with the Program Evaluation and Review Technique (PERT) by the United States Department of Defense (DoD). PERT was introduced by the U.S. Navy in 1957 to support the development of its Polaris missile program. While the term "work breakdown structure" was not used, this first implementation of PERT did organize the tasks into product-oriented categories.

The document has been revised several times, most recently in 2011. The current version of this document can be found in "Work Breakdown Structures for Defense Materiel Items" (MIL-STD-881C). It includes WBS definitions for specific defense material commodity systems, and addresses WBS elements that are common to all systems. Elements of each WBS Element:

• The scope of the project, "deliverables" of the project.
• Start and end time of the scope of project.
• Budget for the scope of the project.
• Name of the person related to the scope of project.

Design Principle

An important design principle for work breakdown structures is called the 100% rule. It has been defined as follows: The 100% rule states that the WBS includes 100% of the work defined by the project scope and captures all deliverables – internal, external, interim – in terms of the work to be completed, including project management. The 100% rule is one of the most important principles guiding the development, decomposition and evaluation of the WBS. It is important to remember that the 100% rule also applies to the activity level. The work represented by the activities in each work package must add up to 100% of the work necessary to complete the work package.

Mutually exclusive: In addition to the 100% rule, it is important that there is no overlap in scope definition between different elements of a work breakdown structure. This ambiguity could result in duplicated work or miscommunications about responsibility and authority. The WBS Dictionary

describes each component of the WBS with milestones, deliverables, activities, scope, and sometimes dates, resources, costs, quality.

Plan outcomes, not actions: When a project provides professional services, a common technique is to capture all planned deliverables to create a deliverable-oriented WBS. Work breakdown structures that subdivide work by project phases must ensure that phases are clearly separated by a deliverable also used in defining entry and exit criteria.

Coding scheme: It is common for work breakdown structure elements to be numbered sequentially to reveal the hierarchical structure. The purpose for the numbering is to provide a consistent approach to identifying and managing the WBS across like systems regardless of vendor or service.

Application in the information management system

In order to better solve the deficiency and defect management information system by using the WBS method. The principle of this method is simple, convenient operation, easy application. The following is a example, that example is the management of project management information system with WBS method:

This system is mainly aimed at the general project management business enterprise,and the development of the system will use the Browser/Server model. Then the paper uses C# to describe them.

```
ListItemit=newListItem;
it.Seleeted=rue;
this.dropType.Item.Items.Insert(0,it);
If(Request.Paranms[“jxNo”]!=NULL)ProjcetType=;
Ruquest
TreeNodeRootNede=newTreeNod;
RootNode.ImageUrl=”../IResource/images/ieon05.gif”;
if(ProjeetTyPe=””)
{       RootNode.TeX=”All of them ”;
ROOtNode.NedeData=””;
ROOtNode.ID=f,TreeViewRoot,,;
InitTyPe(RootNede);
}
Else
{       RootNode.Tex=Type;
RootNode.NodeData=””;
RootNode.ID=”TreeviewProject”;
try
{       //XML Data
catch(Exceptionex)
}       ;{
ResPonse.Write(ex.ToString());
}
InitTree(RootNode,RootNode.NodeData);       }
TreeNodetmpProjectNd;
DataTabledt=newDataTable();
Dt=conn.GetTable;
foreach(DataRowdrTyPeindt.Rows)
{
tmpProjectNd=newTreeNode();
tmpPfojectNd.Text=drType[“DBI_2”].Tostring();
tmpProjectNd.NodeData=””;
tmpProjectNd.ID=”TreeViewProject””;
tmpProjectNd.ImageUrl=””;
tmpProjectNd.SelectedImageUrl=””;
treenode.Nodes.Add(tmpProjectNd);
tmpProjectNd.Expanded=true;
try
{
dtblsProject=conn.GetTable();
}
Catch(Exceptionex)
   {
      Response.Write(ex.ToString());
   }
InitTree(tmpProjectNd,tmpProjectNd.NodeData);
}
```

Running the program could get the more whole graph about the WBS. And you can read the graph to help yourself catch the final goal easier.

Conclusion

In the guidance of the theoretical frame of project management information system based on the WBS, the paper made an example to illustrate. The paper considers the user requirement, analysis system. And there are the compilation code they are the way to catch the goal by using the software. Studies on PMIS should focus on finding ways of enhancing its use by the project principals and administrators. Appropriate training and effective leadership could escalate the benefits of PMIS in the area of project management.

Research of Access Control Models in Personal Networks

Yulan Zhao[1, a], Chunfeng Jiang[1, b]

[1]Jilin Agricultural Science and Technology College, Jilin, China

[a]llbird@126.com, [b]hero_jcf@126.com

Keywords: access control; role; task; personal networks

Abstract.How to prevent illegal users from sharing system resources was one of the main purposes for MAGNET Security Group. This paper introduced some major access control models such as traditional access control models, role-based access control model (RBAC), task-based access control model (TBAC) and role-task-based access control model (T-RBAC). In the end, a feasible scheme PN_T-RBAC was proposed at the base of the T-RBAC model in existence, which was suitable for the coalition environment of personal networks.

Introduction

MAGNET was a large integrated project in the field of information society technology of the EU's sixth framework programme for research, FP6, which means My Personal Adaptive Global NET. MAGNET started around the concept of personal networks. PN was a network that all devices belonged to a particular user, which the personal devices might be local also remote. There was a typical PN contained four clusters as Fig. 1. The first cluster A was around the user's own local cluster, the second cluster B was located in the home, the third cluster C was located in the office, the forth cluster was located in the car, and B,C,D were remote clusters. As communication was between people, there also were dialogue and sharing of resources between the PN. While other PN exchanged through cluster A with this PN, how to ensure secure access to resources in each cluster was one of the goals for MAGNET security working group.

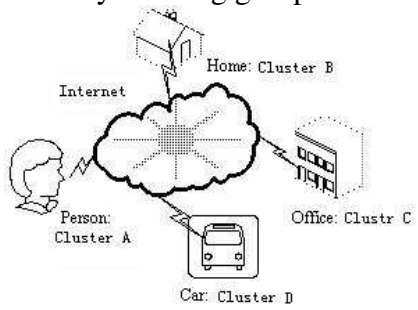

Figure1 a Typical Personal Networks

Access Control Model

Access control model was main method to secure access for networks. Access control model included subject, object definition and authorization policies. The core technology of Access control was licensing strategy, which provided the scheme where the main obtained accessed ability to the object. According to different authorization policies, access control model was divided into MAC-Mandatory Access Control, DAC-Discretionary Access Control, RBAC-Role-Based Access Control, TBAC-Task-Based Access Control and more popular lately T-RBA, which mint Task-Role-Based Access Control. Normally, MAC was too simple and poor flexibility, the principal permission of DAC was too large, to insecure security, gradually being replaced by other models. This article would focus on the analyzing RBAC, TBAC and T-RBAC, and constructed an access control model which fit for PN coalition based on them.

Role-Based Access Control Model. The basic idea of RBAC model was introduced the concept of roles between user and permissions, which achieved logical isolation between users and permissions. The role was a collection that operation could be executable or service could be accessed by the main in system. The biggest advantage of RBAC was its simplified management, the major management of RBAC system was authorization or canceling use's role. RBAC model had a variety of structures, RBAC96 models was widely recognized. In the RBAC system, permissions were not assigned directly to the user, but first assigned to roles, and then the system assigned a role to the user, so user got appropriate access authority according to their roles. When the system function changed or evolved, it would only delete the old character features, add new functions, or define a new role, without having to update each user permission settings, and greatly simplifies permissions management.

Task-Based Access Control Model. Access control model usually achieved secure access control of resources from the perspective of the system, without considering the context of the specific operation during the authorization. The TBAC model changed its attention for security access control from the protection of static subject and object in independent system to the protection of dynamic authorization carried out with the tasks executing. The task was a logical unit in workflow, for a specific function. TBAC model had the advantages of active control, dynamic allocation of permissions, especially fit for security management of workflow, distributed processing and multi-point access control.

In TBAC model, authorizing was described by five tuple (*S, O, P, L, AS*). Where *S* represented the subject, *O* described object, *AS* said the step of authorization, *P* was the permissions activated by *AS*, *L* was survival period of *AS*. *L* and *AS* were notable features of TBAC, which were different from other access control model. When *AS* was triggered, its agent began to have centralized authority that it commissioned, while its life cycle started countdown. During the lifetime, the granted permissions to user depended on not only the subject and object, but also the currently executing task, the task status, the user's permissions during task was active. When the task suspend, permissions were frozen; task resumed execution, permissions were restored; when the task was terminated, permissions were revoked.

Task-Role-Based Access Control Model. RBAC and TBAC in some specific situations would expose their flaws, for example, RBAC could not forwardly control the sequence of task execution, could not cope with the control requirements of workflow system either; compared to the system with high requirements of the overall structural stability, TBAC seemed powerless, it was not suitable lonely as a general policy framework for more complex systems. So many scholars put forward the access control model based on the task and role, aimed at task and roles were referred to the centrality of access control strategy, combined with their advantages, to make up for lack of both. How to achieve the perfect combination of TBAC and RBAC, and build access control model, which had become a hot topic in recent years, the main models were RTBAC and T-RBAC, showed relatively good performance T-RBAC as Fig 2.

The main idea of T-RBAC was the overall framework based on RBAC, while introduced the concept of task, and assigned roles related tasks, then gave the task relevant authority, to achieve dynamic management of permissions. T-RBAC authorization represented with quintuple (*U*, *O*, *P*, *T*, *R*), where *U* was subject who could independently access system resources ; and *O* was the physical

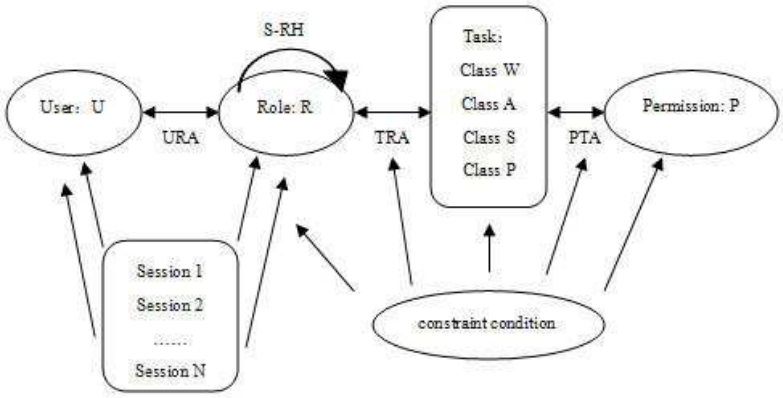

Figure 2 Task-Role-Based Access Control model

resources passive acceptance of other body movements. *P* indicated the role permissions to perform tasks; *T* mint task; *R* were a set of roles which could perform tasks with hierarchical relationship. Before *T* was activated, the privileges of *R* were not available. *URA* was to assign many to many relationships from users to roles, *TRA* was to assign one to many relationships from tasks to roles, *PTA* was to assign many to one relationship from permissionss to task. When *T* was active, *R* began to have permissions, and the permissions would change based on context with *T* performing tasks, then be recycled accordingly as task completed. Therefore, in T-RBAC model, users accessed specific object resources in the system during only the execution of specific orders.

Personal Networks Coalition

PN coalition refers to a temporary commonwealth formed by several independent PNs for current common interests or task. The biggest feature of PN union environmental was resources belonged to several independent PN network systems.

Access Control Model of PN Coalition. While the existing access control technology solved the access control issue of resource in a separate system. For this conflict, PN_T-RBAC, an improved model program was proposed, it could reflected the advantages of existing T-RBAC technology in the PN league environment, shown as Fig 3.

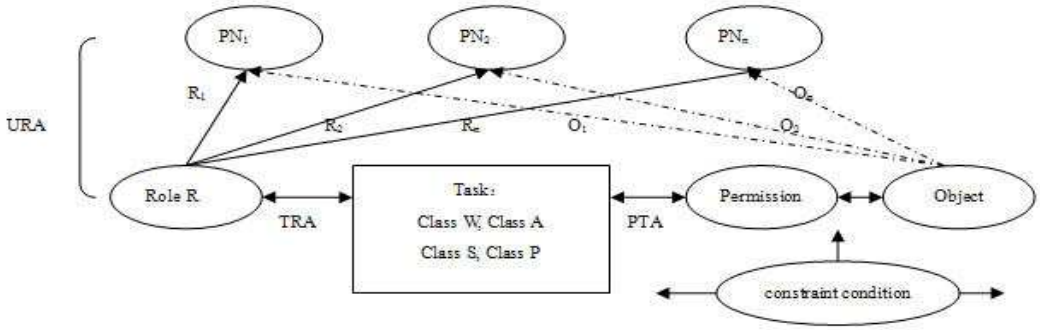

Figure 3 Access Control Model of PN Coalition Environment

Internal Security Structure of PN Members. To achieve each independent member to unify a PN federation model, PN_T-RBAC required each member introduced SMN-service management node in the local security structure. In PN coalition, each PN had its own address, while SMN had its own unique name, they were visible for other league members. Fig 4 indicated the local security structures of members *I* in PN, each member should have such local security structures, and it could be uniquely identified which PN belonged by SMN name. Thus SMN among each PN could negotiate, clarified the rights and obligations of PN in the league, and jointly safeguarded PN_T-RBAC model system. Wherein the specific content that SMN negotiated included a trust

mechanism was established between SMN, the goals or plans of PN Union were determined, the targets were refined number of tasks, the specific content of roles, permissions, and object mapping coalition environment were determined.

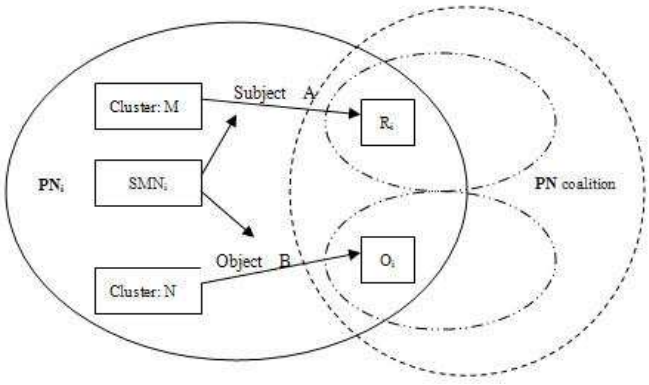

Figure 4 Local Security Structures of Members in PN Coalition

Summary

Personal networks had the potential which communicated with anyone any time, any place, with any form, it must have broad application prospects. This article focused on thesecurity access controlproblems in PN coalition, a viable model programwas proposed on the basis of theprior art. Personal networkwas more complex, as atheoretical model, improved model didn't make practical model system. There were many problems needed to be solved, especially in an environment containing a dynamic cluster.

Keywords: P2P; RTBD; trust model; trust value

Abstract. In this paper, a trust model based on real-time behavior detection scheme was proposed in P2P file-sharing system. It solved the problems in computing trust value only by past performances and choosing service nodes improperly. It took real-time behavior detection both in trust computing and service choosing, improving the accuracy of the trust value and the rationality in service nodes choosing. The experimental results proved the advantage of this scheme.

Introduction

Peer to peer-abbreviation was P2P- networks had been rapid development recently. Applications based on P2P networks were increasingly abundant, the file sharing system for P2P networks had achieved great success on the internet. However, it was a big hidden danger of P2P networks' security when it provided favourable conditions for the spread of computer viruses, forgery, and garbage data owing to the dynamic, anonymity, autonomy and loose coupling between nodes and other characteristics of P2P networks.

It was a really social network environment for human communication provided by P2P networks. Because trust was the core of human relations, researcher introduced trust to file sharing system of P2P networks, and described the relations between nodes in P2P network with trust relationship.

Trust Models for P2P File-Sharing System

It was a really social network environment for human communication provided by P2P networks. Because trust was the core of human relations, researcher introduced trust model to file-sharing system of P2P networks, and described the relations between nodes in P2P network with trust relationship.

Trust model divided the trust content and the degree of trust, and proposed a mathematical model from a subjective measure of confidence to start trusting. In P2P networks, trust was reflected in the service capacity and quality of service. Service capabilities such as computing power, storage capacity, bandwidth, quality of service were reflected in the time-line nodes, friendliness, reliability, service delivery. Dued to the impact of nodes trust relationship factors varied, in practical applications, it was difficult to carry out all of the information fusion trust calculations. Therefore, in the P2P network, the trust between the nodes was identified by of the transaction satisfaction. Currently, the trust of P2P networks mainly established a reliable trust model in P2P networks to resolve.

There were two types of trust models for file-sharing system of P2P networks proposed. The first was structured trust model, its network structure was strictly controlled, and trust value stored in affirmatory location, it ensured the update and query of trust had high efficiency, it could collect trust information in the whole network, and gained global trust value. The structured trust model was often a great deal of overhead, if once the number of users increased, would form a great performance bottlenecks, scalability, relatively poor, and likely to cause a single point of failure. The second was non-structured trust model, its network topology was without any restriction, there wasn't relative between trust value and network structure, it was more suitable for strong dynamic P2P network.

In order to systematically understand the P2P network trust model, the non-structured trust model was divided into trust model based social network, trust model based on probability estimates, trust model based on fuzzy logic, trust model based on game theory. In recent years, dued to the continuous development of social networks, the research of trust model based on social network was endless. Relationships and trust in society and interpersonal relationships were very similar, they were the core of interpersonal trust relationships, and trust between individuals often depended on the recommendation of other individuals, which was based on third-party recommendations indirect trust. In fact, this interdependent relationship of trust form a so-called trusted network. In such a trust network, the credibility of any individual was not absolutely reliable, but could serve as an individual basis to determine their interactions. The trust model based on probability estimates proposed a trust evaluation was divided into both positive and negative, if the transaction was successful, the trust evaluation set 1, otherwise 0, and thus presented a probabilistic model based on the binomial distribution. The trusted computing problems into problem solving mean binomial probability density. Only based on Bayesian/Bayes network trust model focused on describing different aspects of trust, so that nodes could obtain different aspects of the performance of nodes according to different scenarios on demand. When a node could not determine the reliability of the file provided by using the recommendation information to the other nodes established a trust relationship, there was provided a method for the integration of different flexible trust information. The basic idea of trust model based on game theory was to model a system in which each member to achieve their own purposes through the interaction, included the maximization of their function in specific situations, to get the maximum benefit. Interactive game was a member between player and game. D. Houser proposed a framework for a trust model based on game theory to calculate the trust in limited trust environment. C. Dellarocas proposed a specific trust model based on game theory, and for such a trust system, made some enlightening questions, such as how to motivate nodes provide feedback, how to deal with the false feedback. But it required a trust center to collect all of the feedback. There was a big security risk.

Real-Time Behavior Detection Mechanism. The RTBD-real-time behavior detection-mechanism was proposed in this paper, it consisted of two parts. When trust computing, firstly, it obtained trust value of real-time behavior through target nodes, and then integrated with other trust value in the traditional trust model. When serviced for the destination nodes, it not only considered the nodes trust value, but also assessed the target node's service capacity and service quality with real-time behavior detection mechanism, integrated trust value and service quality to select the service. Real-time behavior detection mechanism avoided effectively overloading the nodes which had high trust value and others with good service were free as the same time.There were five symbols in RTBD, TV meant trust value, RTV was recommended trust value, RTBTV was real-time behavior trust value, DTV was direct trust value, PTV was past trust value.

Real-Time Behavior Detection of Trust Computing. The risk of P2P file sharing system which based on historical behavior was historical behavior could not represent current conduct, some nodes could be malicious behavior as slander, collusion after obtained a high trust value by providing good service. Although most of the trust models proposed appropriate punishment mechanism to curb the malicious behavior of nodes, the problem was not fundamental solution. The concept of observation period was introduced. System would observe the behavior of downloaded nodes before downloading and the observation would be the other basis for trust value calculating.

The traditional trust models were simply calculated trust value of target nodes based on their historical behavior. The trust value included two parts; they were direct trust value-DTV and recommended trust value-RTV as Fig. 1. In trust models which used real-time behavior detection mechanism, trust value comprised past behavior trust value-PTV and real-time behavior trust value–RTBTV as Fig. 2. The RTBTV was from evaluation of immediately dynamic data. The real-time behavior would be past behavior after real-time behavior finished, so RTBTV was a relative item to PTV. The direct trust value and the recommended trust value constructed PTV.

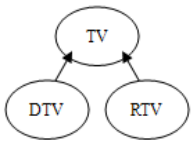

Figure 1 Traditional Trust Value Composition.

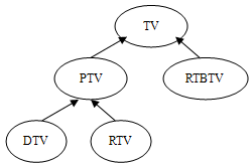

Figure 2 RTBD Trust Value Composition.

The traditional trust value could be expressed as in (1), in RTBD; the trust value could be expressed as in (2). α, β and γ were trust factors, their values would dynamically adjust according to actual networks. α, β would be reduced and γ would be increased when malicious nodes were more.

$$TV=\alpha\times DTV+\beta\times RTV,\ \alpha+\beta=1 \quad (1)$$

$$TV=\alpha\times DTV+\beta\times RTV+\gamma\times RTBTV,\ \alpha+\beta+\gamma=1 \quad (2)$$

The RT-response time and QOF-quality of files were standards of measure to the RTBTV. The response time defined as the time from user sent files requester to receive a response. The quality of file defined as the fit degree of file hash values between users gave and received from target node. So the *RTBTV* could be expressed as in (3).

$$RTBTV \propto QOF/RTV \quad (3)$$

Real-Time Behavior Detection of Select Services. The disadvantage of traditional trust model was that target nodes' service capacity could not be effectively since they selected node which trust value was highest as service node. On the one hand, it easily led to too overloading to cause single point failure of highest trust value node. On the other hand, the resources on some nodes which had higher trust value could not use fully, and it deprived them of the opportunity to enhance trust value. The RTBD mechanism selected service nodes based on trust value and CR-congestion rate, it selected node which had higher trust value and lower *CR* as service node. The congestion rate was defined as in (4).

$$CR \propto L/C \quad (4)$$

L was the load of nodes; *C* was load capacity of nodes. When *L*>*C*, the nodes were congested, otherwise, *L*<*C* meant they were non-blocking. RTBD policy was as table 1.

Table 1 RTBD Policy

Step	Description
1	Get a pool of service providers $S=\{S_1,S_2,...S_i...\}$

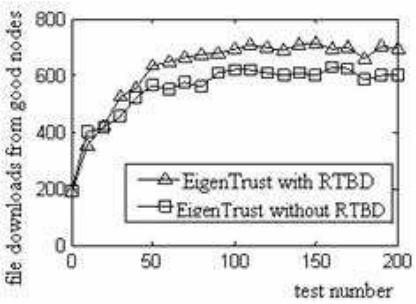
2	For each node S_i in pool S
	Request the attribute of node S_i <content_hash, L,S,C>
	Get the hash value of the content
	Content_hash=hash_fuction(pack.content);
	Calculate the congestion rate
	CR_i=cong_fuction($S_i.L$, $S_i.C$);
	Get required hash of pack.fileno;
	Evaluate the quality of file and response time;
	Eval_result=eval_fuction(content_hash,reply_hash, response_time);
	If (Eval_result) that meant receiving right packet then
	Add S_i into it local cache, store the content of packet into the
	Data buffer;
	Else remove S_i from local cache;
	Endif
	Output the result as <eval_result, CR_i>;
	Endfor;

3	Choose the provider with higher trust value and smaller congestion rate

Simulation Experiment

The performance of RTBD mechanism was tested in the classic trust model of file-sharing system in peer to peer network-Eigen Trust, through simulated experiment. There were three types of nodes in experiments, good nodes-which provided well files, normal nodes-which furnished well files as well as malicious files, malicious node-which supplied malicious files.

The number of file downloads from good nodes and malicious nodes were recorded in peer to peer network. In the same experimental condition, two hundred tests were simulated, there were one thousand downloads requests each test, the number of file downloads from good nodes was compared in Eigen Trust in system between which used RTBD mechanism and it without RTBD mechanism. The result was described as Fig. 3. In the experimental progresses, there was faster growth rate of document downloads from good nodes in Eigen Trust with RTBD mechanism, its file downloads was 100 more than the Eigen Trust which without RTBD in the same network condition, that meant RTBD mechanism was benefit to improve the trading volume level of system. Trust model was not only to encourage good behavior of the network good nodes, but also to suppress the malicious behavior of malicious nodes. There were one hundred tests in the same condition for file downloads from malicious nodes, one thousand download requests each test. As records, file downloads of test with RTBD mechanism decreased more rapidly than it without RTBD mechanism as Fig. 4.



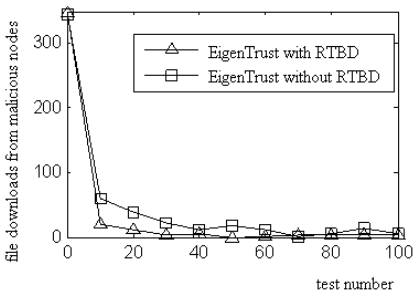


Figure 3 File Downloads from Good Nodes. Figure 4 File Downloads from Malicious Nodes

Summary

In the trust model of peer to peer network, a new real-time behavior detection mechanism-RTBD was proposed based on traditional trust models. It could achieve accurate trust value and choice reasonable service nodes used RTBD in trust value computing and service nodes selection. The follow-up work of RTBD mechanism was to apply it to more trust models.

Keywords: ZigBee; CMOS camera; ARM processor; Compress.

Abstract. ZigBee technology is mainly used in short distance, low power consumption, low rate, low complexity of equipments for data transmission. When image has a large amount of data, it should be processed firstly, and then transmitted. This essay makes a research on healthy care system, using CMOS camera to get image and compress image. Then, the compressed image is transferred to ARM processor, and divided into data packets according to the requirement of the ZigBee network transmission. Finally, the image is transferred to control center and displayed. After the final test, this system can get images to meet the requirements, which has some practical values.

Introduction

At present, the wireless image transmission mostly uses the GPRS/CDMA technology, Within the scope of the GPRS/CDMA network coverage, the images can be transmitted steady. But in some specific cases, the transmitting base station appear problem, the whole networks would be paralyzed. But the ZigBee technology can solve the disadvantages well,just only one gateway node can organize a network, the other nodes can join the network directly or join the network by way of multiple hops.

ZigBee is a low power consumption, low cost, short time delay, network of large capacity, high security features two-way communication technology, wireless sensor network (WSN) has been widely used in embedded devices, automatic control, industrial control, medical monitoring, intelligent household and other fields. But because of its small bandwidth, low transmission rate, when the transmission data is large data files such as image, audio and video, it may met a bottleneck. To address this issue, this essay establishes a image collection and transmission system based on ZigBee under the research background of the community home endowment system. The system chooses a village as the ZigBee network coverage, and install cameras in the monitoring objects'rooms, the monitoring center can send photo instruction according to the need, to collect real-time image and get the real time status of monitoring objects.

The overall structure design

The system mainly includes two parts of upper computer and lower computer, the lower computer is mainly used to take and transmit image, the upper computer is mainly used to process and display image. The overall structure of the system is shown in figure 1.

The upper computer of system is mainly composed of CMOS camera installed in room, ARM processor and ZigBee module nodes, which called end device. It takes images and transmits the image from the ZigBee routing nodes to the ZigBee gateway node. The gateway node is connected to the PC and responsible for the establishment of the network, at the same time it receives data from multiple routing nodes, transmits the collected images to the monitoring center. The user interface software is developed based on Visual C++ 6.0 in Windows.

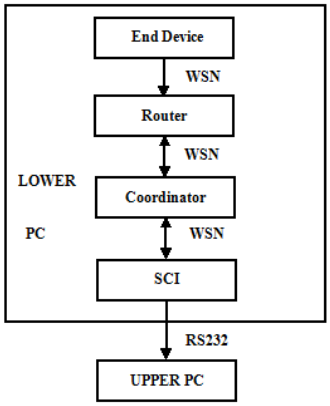

Figure 1. System structure Figure

The Hardware Design Of The System

There are three types of ZigBee protocol about the network topology structure: star structure, tree structure and mesh structure. Mesh topology structure has a high ability to adapt to the environment. Every node in the network is a small router, all have the ability to reroute choice, in order to ensure the reliability of the network to the greatest extent. In a mesh network , each node can communicate with at least one other node, this approach can achieve better than a tree or a star topology of network connectivity. So according to the characteristics of this system, a mesh network topology structure is more suitable for this system.

Routing nodes and gateway nodes of the system, adopted based on ZigBee CC2530 suite for development platform. CC2530 not only support 2.4GHz IEEE802.15.4 /ZigBee standards of practical application, but also have high cost performance, can be at a lower price to form a powerful network performance.It is a combination of standard enhanced 8051 CPU and the advantages of the RF, and own the larger programming space at the same time.

The end device is mainly composed of PTC08 serial camera based on VC0706, ARM processor of S3C44B0X, and CC2530 ZigBee modules.

PTC08 serial camera can be used for image acquisition, control, data compression, serial transmission. Its built-in high-performance digital signal processing chip implements to the high proportion of the original image compression. The output image through the camera is compressed standard JPEG format. At this time, the image data is still big, and do not conform to the requirements of the ZigBee network transmission byte size. So it need to transmit the image to the ARM processor, then according to a certain compression algorithm to the subcontract the image data,and at last traveled through the network transmission. The lower computer work process is shown in figure 2.

The software Design Of The System

The entire image transmission system can be divided into the following three modules: data transfer module, data processing module, image data storage and display module, as shown in figure 3.

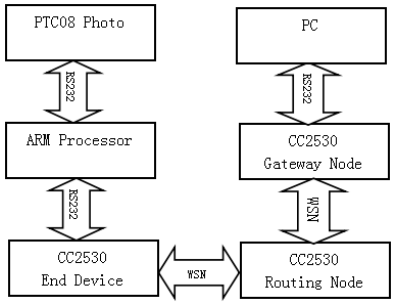

Figure 2. Lower computer flowchart Figure

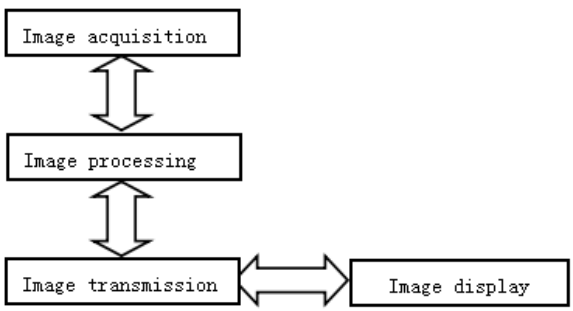

Figure 3. System function figure

The data transmission module programming

ZigBee network wireless transmission module mainly realizes the data transparent transmission, that is when the PC exchange data with the camera, only need to consider whether there is data to send, and don't need to consider the format of send instructions. When the image data the camera takes sent via routing nodes, it must be divided into a number of data packets according to the requirement of the ZigBee network , and then send each packet in order. In the gateway nodes receive the sent data in order and transmit the data to the PC software to decode, so as to complete the whole process of large amount of data transmission.

The data Processing module programming

The main task of this module is to receive the image information the serial port camera send, then the data were processed and sent out by ZigBee routing nodes. In the process of processing and data communications,it need ensure the integrity , safety and accuracy of the data. Because ZigBee network can only transmit data in low speed, so the most complicated problem is to realize function that the image data subcontract firstly and then to send.

The Image display module programming

When the image data subcontracted transmit via wireless network to the PC machine, PC software needs to extract the sequential packets according to certain decompression algorithm and then to display.

The system test

According to the above system hardware and software design, completed the development of this system. And the system was tested, the test results are shown in figure 4 and figure 5.

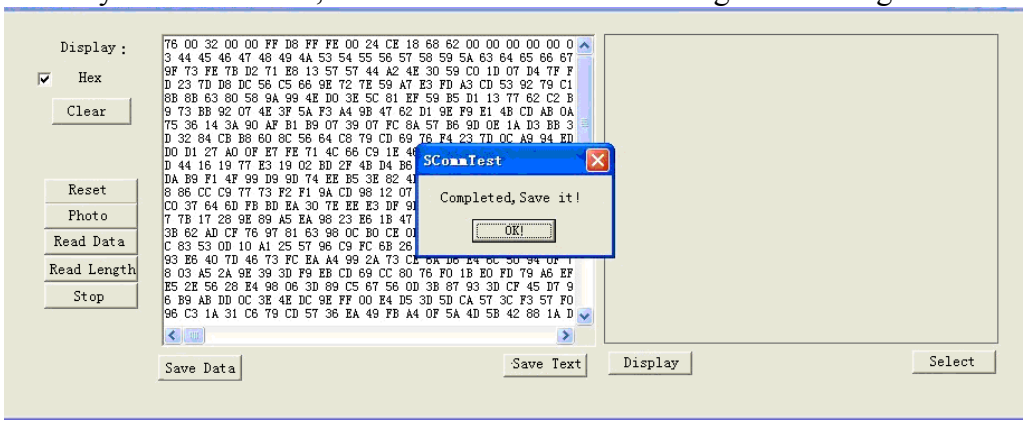

Figure 4. Image hexadecimal representation Figure

This study constructs the whole image transmission system, uses serial camera to collect information in the old man's living environment. This system gets through RS232 data processing module to transmit data to the ARM processor and then the ARM UART module pass the data to ZigBee routing nodes, eventually it reaches the ZigBee wireless transmission center through the ZigBee network nodes. It displays image data finally back into the original after processing, which transfers data to PC using the connection between the PC with the RS232 module. The image data of this study can dock with the existing home endowment system database for storage that can enrich the data. During the development process, this design completes the hypogyny machine program's design and the implementation of the PC software. The camera image information acquisition mainly use the serial port based on VC0706 chip during the development process about the Lower computer. Lower computer system uses serial camera based on VC0706 to collect image information, ARM development board based on S3C44B0X to divide image information into many

data packages, ZigBee modules based on CC2530 to construct wireless network for data transfer. Upper computer system uses VC6.0 and ADS1.2 to develop program, realizes serial communication and .original image display.

Figure 5. Image display Figure

When the upper computer software send photos command, the camera take images, send the image data back to the software. Figure 4 shows the sequence to reach the PC software hexadecimal data information of the image and click save data button, the image data file stored in JPG format. Then click the button, the image will display as JPG format. Set the size of the image resolution 320 * 240 when test, the image size returned is about 13 KB, which can be clearly seen from figure 5 captured image,and this realize the wireless transmission of images.

Conclusion

The paper introduces the design of image getting and transmission system based on ZigBee from two aspects of hardware and software. At last, the design of the system is realized. Pass the final test, it can get the real-time captured images clearly. In the healthy care system, it can well help doctor understand the patients' condition. At the same time, it also provide important design idea for the wireless sensor network (WSN) of large amount of data in the file transmission, and it have certain research significance and practical value.

Email: zshazhu@163.com

Keywords: engine system; behavior analysis;

ABSTRACT: the user behavior analysis is the effective way to enhance the user viscosity, large Internet sites to maintain the flow. meanwhile efficient processing and storage, cloud database test showed that, the system can significantly improve the effect and efficiency of user behavior analysis.

0 Introduction

The dynamic behavior of user refers to the user (including login and not logged in two cases. The user login, registered account user identification by acquiring ID; for users who are not logged in, record visit their website SessionID logo) occurred in accessing the page a moment of behavior, the behavior includes the occurrence time, the page (contains the page title and page URL), related to the operation and behavior subject, real-time capture them and carry on the effective analysis, has an important significance for understanding user behavior characteristics[1].

From the client gets information including the user dynamic behavior and context information, the context, including: behavior occurrence time; the current user ID or SessionID; the current page title; the address URL of the current page; the current user search conditions; access to the same page number; page retention time; do you want to save the page; printed the page whether or not ;whether add to favorites ; copy or cut the page content and so on ; the environmental context information includes: the client machine configuration, current network condition, the server working condition etc..

1 The historical behavior mining

Analyzing the historical behavior mainly comes from on the WEB log mining[9], due to a surge in the number of Internet, the amount of data the WEB log and exponential growth, which makes the analysis platform of based on the single node has been unable to meet the needs of massive data analysis[2]. Therefore, the analysis engine user behavior based on cloud platform, the cloud storage technology will be the mass of WEB log is stored in the HDFS distributed file system, and the calculation model by using MapReduce, the log file cleared, denoising, protocol, finally, on a variety of data mining algorithms are parallelized modification, in the form of services to the users with mining analysis functions, including: analysis, research, user behavior improved matrix vector association rules method based on clustering algorithm based on user interest degree of user behavior query vector space model based on cloud environment, mining results, stored in the HBase user behavior information base, in order to combine with the dynamic behavior, reasoning user interest. In order to enhance the efficiency analysis of log file.

2 Study on the vector space model of retrieval based on user behavior

Vector space model (VSM:Vector Space Model) proposed by Salton and others in twentieth Century 70 years, it is the basic idea of each text and query contains some features independent properties reveal its content, and each feature attributes can be regarded as a dimension vector space, then the text can be expressed as a collection of these attributes, ignoring the complex relationship

between paragraphs, sentences and words in the text structure[3]. At the same time, given the feature weight vocabulary certain (weight), anti should vocabulary in the importance and the value of the contents of the file identification, this value is called the indexing vocabulary "significant value (Term Significances)" or "weight", by the lexical statistics calculate the document and to, such as: the feature words appear frequency (Term frequency, TF). Vector of each file is in fact all the document feature through a combination of computing, called "the document feature item vocabulary matrix". And then all of the document vector based on specific computing methods of similarity measure between each other.

Vector space retrieval model can be described as $I=(D,T,Q,F,R)$ Among them:

$D=\{d_1,d_2,...d_n\}$ As a collection of text, n text collection number;

$T=\{t_1,t_2,...t_n\}$ Set as a feature, m feature of all. A text m feature indexing can be represented as a vector space $d_i=\{w_{i1},w_{i2},...w_{im}\},i=1,2,...,n$, w_{ij} is characteristic t_j for the text d_i of the weight, if the weight value w_{ij} is 0, indicating t_j that it is not appeared in d_i

$Q=\{q_1,q_2,...q_m\}$ for the query set, a query q_r can be represented by vectors $q_r=\{q_{r1},q_{r2},...q_{rm}\}$, q_{rj} is a characteristic to t_j the query q_r weights, if the weight value q_r is 0, indicating that t_j is not appeared in q_r.

Further definition:

Frequency tf_{ij}: t_j is the feature for text d_i appear in the frequency;

Inverse document frequency word idf_i (inverse document frequency): the word in the quantitative distribution of document collection, the calculation $\log(N/n_k+0.5)$ is usually, where N is the total number of document centralized, n represents a number of documents containing K, called the document frequency of the term.

The normalization factor: in order to reduce the inhibitory effect of high frequency characteristics of individual word on other low-frequency feature words, the standardization of components.

Based on the above three factors to term weighting formula:

$$w_{ik}=\frac{tf_{ik}\log(N/n_k+0.5)}{\sqrt{\sum_{k=1}^{n}(tf_{ik})^2\times[\log(N/n_k+0.5)]^2}} \quad 3.1.$$

The similarity between the text and the query can be used to measure the distance between two vectors. There are many kinds of calculating method of similarity, commonly used methods of inner product, Dice coefficient, Jaccard coefficient and cosine coefficient, usually uses the cosine coefficient method, namely the cosine of the angle between two vectors to represent the similarity between the text and the query $Sim(d_i,q_j)$, see equation (3.2). Cosine similarity calculation method

is a normalization, the angle between the two vectors of the smaller, the greater the degree of correlation between documents, correspondence $\cos$ is higher. Two vector included angle cosine is equivalent to their standard vector inner product unit length, it reflects the similarity term component two vector of relative distribution.

$$Sim(d_i, q_j) = \cos\theta = \frac{\sum_{k=1}^{n} w_{ik} \times w_{jk}}{\sqrt{(\sum_{k=1}^{n} w_{ik}^{2}) \times (\sum_{k=1}^{n} w_{jk}^{2})}} \tag{3.2}$$

Algorithm design

Input: user access to key words each time the user query log in;

Output: the similarity with the query keywords vector existing values in the database is not paper and similarity of 0, and according to the similarity value from big to small order;

1）extracted from each Webpage keywords as the feature word, and these feature words and keywords query every time the user binding, rearrangement and according to a lexicographic order, combined together to form a standard feature set of words;

For example, there are Webpage document set (NDoc1, NDoc2, NDoc3, NDoc4), all the feature words together for (W1, W2, W3, W4, W5, W6), and when the query words (WQ1, WQ2), where wq1= W4, the standard set of words as features (W1, W2, W3, W4, W5, W6, WQ2), Webpage document feature item vocabulary matrix in table 1.

3 Application examples

Using the above research results, relying on the research project, the analysis engine system user behavior based on cloud computing is a design and development[4].

The analysis engine platform running on the Ubunt12.10 user behavior, the software mainly includes: jdk-1.7.0_11, Jena-2.6.4, Myeclipse-8.0, Hive-0.10.0, HBase-0.94.4, Hadoop-1.0.4, Tomcat-6.0, Jquery-1.6, Spring-3.0, Struts2-2.2.1, the browser is above IE8.0. The context aware behavior analysis as an example, system operation is as follows:

The system calculates the Markoff matrix intermediate important, as shown in figure 2.

4 Research and Prospect

User behavior analysis engine through the WEB log, the user dynamic behavior and the context information, multi-channel, all-round, three-dimensional access to large-scale user behavior information increasing, the use of cloud environment MapReduce parallel computing model, HBase cloud storage capacity, and uses the relevant data mining algorithms, static analysis, dynamic monitoring of user behavior characteristics and synthesis reasoning, behavior of rich information content, comprehensive, complete, and can efficiently for the user to push their interested information and provide the basis for the site structure adjustment.

Because of the time and energy constraints, this work is currently only integrates three cloud platform of the data mining model, looking for more scene data mining model, and transformation, in the cloud platform integrated, make the system more universal, universal, is the next step of work to do.

Keywords: UPNP AV; OAuth; Media Server; Open Platform

Abstract. Universal Plug and Play (UPnP) is a technology for devices interconnection and resource sharing in the home network. However, the UPnP network has a construct. User can only access local resources within the UPnP network, but user is Unable to access the resources outside the home network such as the resources of the user on the Internet. Now social network is popular, the user has a lot of resources in their own social network. How can the user realize resource sharing on social network to the UPnP network? It can make user can easily access to the user's social resources on the network in their own UPnP home network. We found that most of the social network based on open platform OAuth authorization to third party that call the API to access the resources in social network. We now put forward a solution that is based on the architecture of UPnP AV, we can extend the media server's function that call the social network open platform API to realize the resources sharing between social network and the UPnP network.

I. Introduction

UPnP [1] is a network protocol that UPnP forum proposed and implemented to promote a set devices interconnection. It is also a uniform standard. UPnP technology defines the various kinds of intelligent electronic devices and household devices such as peer to peer connection of the network. This protocol's goal is to make home network device can be connected and realize resource sharing, but the UPnP network has a construct that user can only access local resources in the UPnP network. After various kinds of electronic devices' interconnection and resource sharing of the home network, People hope that the home internal network resources can be extended to the external network. In other words, people in the home network can access resources outside the home network. There is no regulation and the corresponding solutions in the UPnP technology. It also become a UPnP technology's research direction in the future .

In the paper, we put forward a solution that make the resource Sharing between social network and UPnP network. In Section II, we introduce the basic knowledge of UPnP AV [2] frame and OAuth [3] protocol for open platform authorization. In Section III, we introduce the model of our solution. In Section IV, we set up the experimental environment and analyze the simulation results. In Section V, we conclude this paper.

II. The UPnP AV And OAuth Protocol For Open Platform Authorization.

In the section, we make a brief introduce of UPnP AV frame and the OAuth protocol that used for open platform's authorization in social network.

A. UPnP AV frame

UPnP AV is an important framework of UPnP, it consists of control point, media server, and media renderer [4]. We can make the media renderer play the specified media resource on the media server through the control point's control.

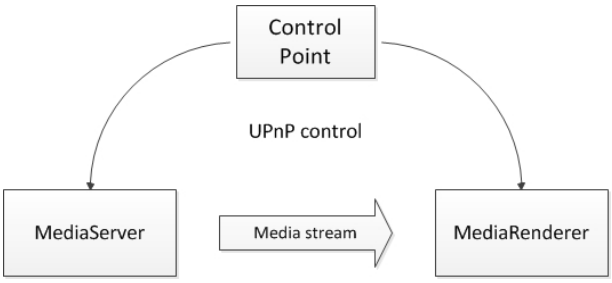

Fig. 1 The model of UPnP AV frame

- Media Server: It includes a lot of media resources. The main role of the media server is used to locate the media resources [5]. These resources are stored in the media server or other devices that media server can access to.
- Media Renderer: Media Renderer is used to play media source from the media server through the UPnP network's transmission.
- Control Point: It is used to coordinate and synchronize media server and media renderer. It makes the media server and media renderer establish connection and transfer media source from media server to the media renderer through the control of the control point. Noted that when the media server and media renderer establish connection and begin to transfer media resource, then control point is irrelevant [6]. The control points and media server or media renderer's interaction is independent.

In the UPnP network, control point found the media server and media renderer and get the devices description such as media resources' URL, transport protocol and data format supported by media server and media renderer. Then Control points call actions to make the media server and media renderer's connection established. At the time, control point can select the media resources in the media server and call the media renderer to play.

B. OAuth protocol

Each user has a lot of resources such as photos, video, music, and so on in their social network sites. Many social network sites are now provide a wide range of Open API for users calling to access their resources, but user must get the owner of the social network resources' authorization. If we get the authorization, we can access to the resources on the social network through third party applications. In other words, we design a scheme that can make our UPnP devices get the authorization of our social network [7]. So we can call the Open API of social network in our UPnP network.

Now, most social network sites are popular in using OAuth authorized technology. The OAuth workflow [8] is as shown in the figure.2.

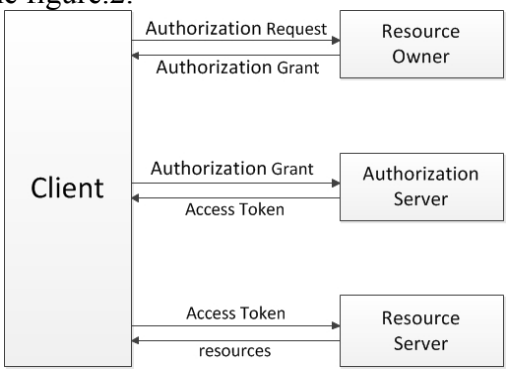

Fig. 2 The workflow of OAuth authorized technology

There are client, resource owner, authorization server and resource owner four parts in the OAuth authorized technology. The user send authorization request to resource owner through a third party. If the resource owner agree with this authorization, the resource owner send authorization grant to the client. Then the client send the authorization grant to the authorization server for getting the access token. When the client get the access token, it can access to the resources of the resource server.

III. The Model Of Our Solution.

In the section, we will introduce the model of our solution. The model of our solution is as shown in the figure.3.

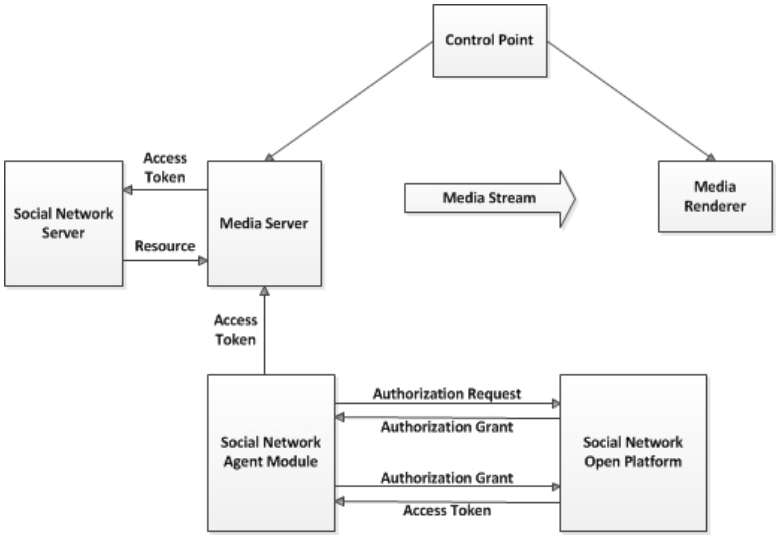

Fig. 3 The model of our solution

In our solution, we make the media server act as the third party client in the OAuth protocol. In the workflow of our solution, there is a social network agent module in the media server. We register a application through enter our account and password on the social network open platform. Then we get the AppKey and AppSecret. The AppKey and AppSecret represent our application. We send authorization request to the social network open platform to get the access token through the social network agent module. When the agent module get the access token, the media server get the access token through the agent module. The media server can call the open platform API to get the resource URL through the access token. So when the control point found the media server, it can get the social network resource URL and the UPnP network's local resources. The control point can call the media renderer to play the UPnP local resources or social network's resources selected by user.

IV. Performance Analysis.

In the section, we set up the experimental environment and analyze the simulation results.

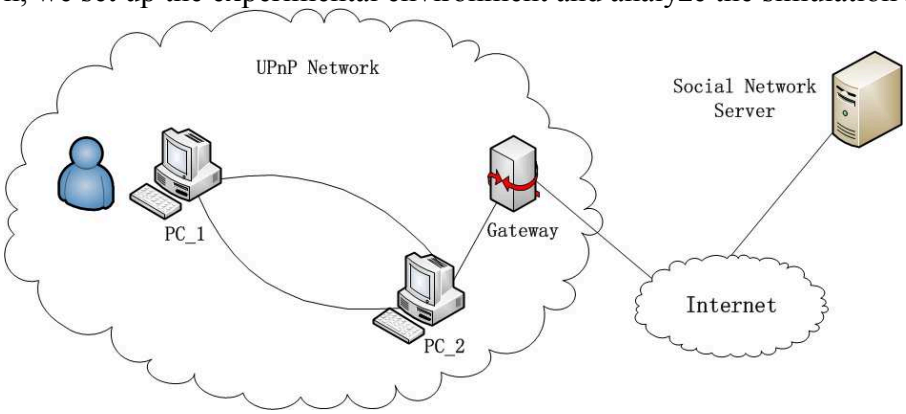

Fig. 4 The model of experimental environment

We use two computers to set up the environment. A computer will be act as the media server, the other act as the control point and media renderer. We use web browser act as our media renderer. In our UPnP network, we set up the http connection between the computers. On the two computers, we are all based on the Eclipse development platform to realize its function in the Java language on the Windows operating system. We use sina microblog act as our social network.

In our simulation experiment, we found the media server and get the local picture URL through the control point, then we call our browser to show it. We send the local picture to microblog through

calling the interface in the open platform. Now media server can get the picture URL in the sina microblog through calling the API. At last, we show the picture through the control point call the browser. The result as shown in the figure.5.

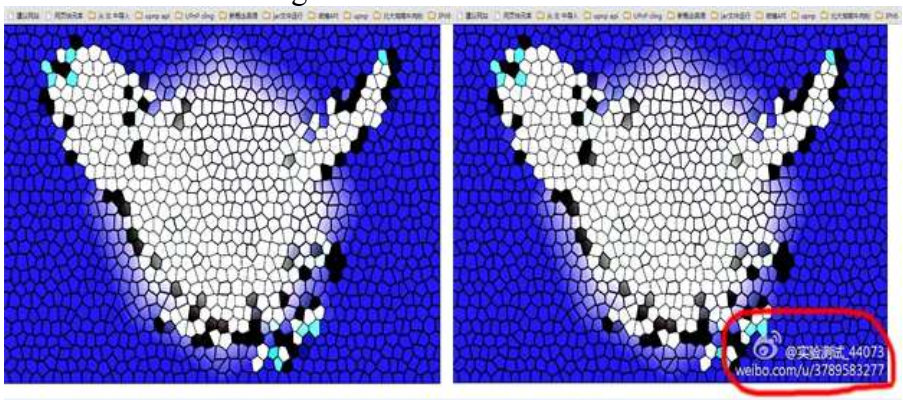

Fig. 5 Compare the picture in the UPnP network and social network

We found that the pictures on the microblog are signed by watermark logo. After we send the local picture to the microblog by media server calling the API, the picture will be the resources in the microblog and are signed by watermark logo.

V. Conclusion.

Based on our OAuth authorization, we make the media server can call social networks open platform API. We expand the media server's function and implement the resources sharing between social network and UPnP network. Through our experiment simulation and the picture demonstration, we proved that we can use the UPnP network's local resources and social network's resources in our UPnP network. Besides, we can interact with social network and make the local resources upload to the social network.

Research and Design on P2P Business Process Execution Framework for Workflow Management Systems

Tao Wu[1, a]

[1]Department of Computer Science and Technology, Tsinghua University, Beijing 100086, China;

[a]violin2696@gmail.com

Keywords: Business workflow, distributed execution, process migration, load balance scheduling.

Abstract. Efficient business workflow management in large-scale areas is in great demand. However, current business workflow management systems are short of distributed workflow execution support. In our paper, we design and implement a distributed framework called PeerODE for Apache ODE (Orchestration Director Engine) [1], an open-sourced business workflow engine. PeerODE presents a scalable approach to P2P business process execution. The scheduling experiment on PeerODE shows that the framework handles the distributed business process execution effectively.

Introduction

Business workflow management is a rapidly growing research area. The technology has been widely used in enterprise management, manufacturing management, etc. As the scale of these organizations increases, workflow management in distributed areas is in great demand.

Current workflow systems include business workflow systems, scientific systems, etc. Most of their architectures fall into three categories: server/client, cluster-based and P2P. Their representatives are METUFlow [2], Pegasus [3] and SwinDeW [4], separately. Only the P2P architecture can offer us the ability of distributing workflow engines in wide areas. The server/client and cluster-based workflow systems have single point of failure problem while P2P systems don't. These metrics make P2P architecture an appropriate choice for distributed business workflow systems.

While business processes can execute normally in a single node, problems come when the processes execute from peer to peer. The business workflow's design focuses on process integrality, so distributed execution needs process slicing and migration support. Current research on process migration are mainly about process execution with different schemas [5, 6], with little attention on process slicing and migration [7]. The PeerODE framework proposes a process migration module to slice and migrate business processes from one peer to another. This module can help business processes execute on peers in wide areas.

PeerODE has peer management module to manage data and control requests between peers. The framework also supports human task since it's an essential part in business workflow. PeerODE chooses BPEL (Business Process Execution Language) as its business modeling language and Apache ODE as its execution kernel.

PeerODE adds a scheduling framework and implements a load balance algorithm. The algorithm migrate business processes from heavy-load peers to light-load peers. The scheduling results can verify the correctness of the process migration module and the function of the whole framework.

Design of the PeerODE Framework

Architecture. As shown in Fig.1, the PeerODE framework consists of five parts.

ODE Engine module is the BPEL process execution kernel. It can execute BPEL processes and communicate with outer web service. The control layer of ODE Engine can receive different kinds of operation requests, such as suspend and replay, on specified processes. The engine can also communicate with local modules through integration layer.

Peer Manager module communicates with other peers through JAVA NIO (New IO) interface to form a P2P network. The module is also responsible for processing data and control requests from remote peers and inner modules. For example, Peer Manager can tell other peers the number of processes in its own peer's ODE Engine module, and it can also help the Scheduling Framework module of its own peer to suspend a specified process in other peers.

Process Migration module implements the function of process slicing and migration. The process executing in the ODE Engine module can be suspended and migrated to other peers to continue its execution from the original suspending state.

Human Task module supports integrating manual work with abstract BPEL activities. The module uses message queue to map the start and end of manual work to the start and end of Invoke activity, a kind of abstract BPEL activity. In this way, the ODE Engine can execute manual work just the same way as executing an ordinary BPEL activity.

Scheduling Framework module is a peer state monitor. It can monitor different kinds of characteristics of the peer. In this paper we implement a load balance algorithm. The algorithm keeps an eye on the number of processes in the ODE Engine module. If the processes number exceeds the upper limit set by Peer Manager, the algorithm will ask Peer Manager to find light-load peers in its neighbor of P2P network and migrate over-loaded processes to the idle peers.

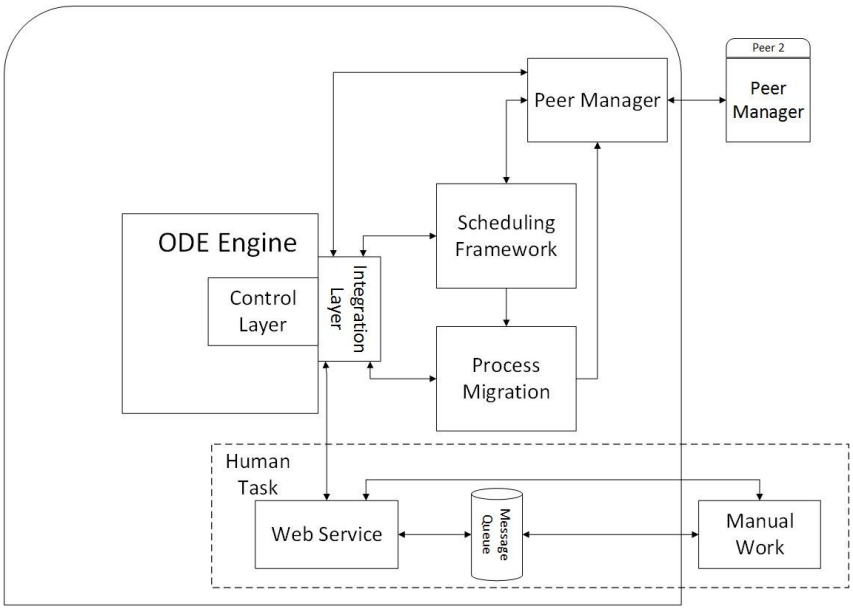

Fig. 1 PeerODE architecture

Execution Procedure. The business process distributed execution is mainly conducted in the PM (Process Migration) module. This module uses four functions of ODE Engine control layer: Suspend, GetCommunication, Replay and Terminate. Suspend helps suspend specified processes. GetCommunication can get process execution history. Replay helps quickly reproduce the process state from execution history. Terminate can delete specified processes from ODE Engine.

As shown in Fig.2, process migration begins when PM suspends and gets execution history of the specified process through ODE control layer, which is the process slicing procedure. If the ODE Engine is executing human tasks, the suspend function will not response until the manual work completes. Then PM sends the execution history to the remote peer. After receiving the execution history, the PM module in the remote peer can reproduce the process state and continue the execution. To this point, the business process migrates from one peer to another, which is indeed a successful distributed execution. The last step is to terminate the original process. It ensures that only one instance of the migrated process exists in the whole system at the same time.

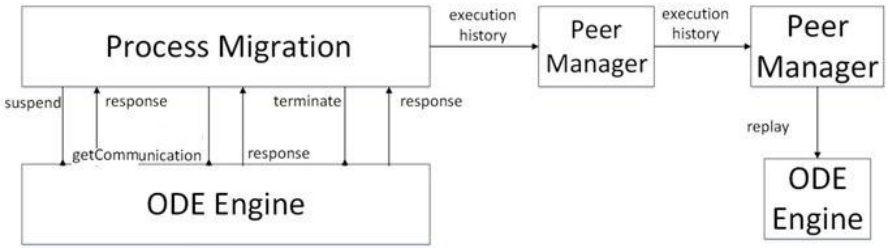

Fig. 2 Execution procedure

Principle Analysis. The two key points of process migration are obtaining business process execution history and reproducing execution state. Process execution history is the history of BPEL activities' messages. During the BPEL process execution, the ODE Engine records the input and output message of every executing activity. These messages can determine the unique execution history of current process, which guarantees the effectiveness of process slicing. The execution state reproduction is through the Replay function of ODE Engine control layer. The function is intended for failure recovery. We rewrite the function for general process state reproduction. The function analyzes the received message history to get the unique execution history. Then it quickly takes the ODE Engine through a mock execution to the process state before suspending. After the mock execution, it begins to invoke real new BPEL activity next to the suspending point and continues the distributed execution.

Scheduling Experiment

Experiment Design. As shown in Fig. 1, the scheduling framework is located in the middle of Peer Manager, Process Migration and ODE Engine. These three modules communicates with the algorithm in the framework, through which we can observe the execution state of the three modules. The scheduling algorithm in the experiment is a load balance algorithm.

In the experiment, 3 peers are launched to form a P2P network. Each peer has different number of processes executing concurrently in their ODE Engine module from the experiment begins. These processes are all the same. The upper limit of process number in each peer is 10. The experiments can verify the correctness of distributed process execution and the effectiveness of the scheduling algorithm.

Result and Discussion. The experimental result is shown in Table 1. We conduct 5 group of experiments. In each group, we have 2 experiments in comparison. Their initial load condition is same to each other. The only difference is that the experiment in the upper row has load balance algorithm monitoring itself while the experiment in the lower row has none algorithms.

The measured variables in the experiments are: average process execution time, load condition of 3 peers. The experimental result is shown in Table 1.

Table 1 Experimental result

Experiment Group	Initial peer load			Final peer load			Average process execution time (ms)
	Peer1 load	Peer2 load	Peer3 load	Peer1 load	Peer2 load	Peer3 load	
1	10	10	0	10	10	0	17277
	10	10	0	10	10	0	17283
2	20	0	0	7	3	10	28450
	20	0	0	20	0	0	30850
3	25	0	0	9	2	14	28795
	25	0	0	25	0	0	35101
4	30	0	0	8	6	16	36581
	30	0	0	30	0	0	45822
5	35	0	0	8	8	19	37654
	35	0	0	35	0	0	44214

From the experimental result, we can see that except for the first group, all the experiments with load balance algorithm monitoring successfully migrate processes from heavy-load peers to light-load peers. The result can not only prove the correctness of scheduling algorithm, but also convince us that distributed business process execution framework is effective. The reason why experiments in the first group do not execute process migration is that the load of their peers has not exceed their upper limit. Since process migration also need system resources, it's an appropriate choice not to migrate processes when all the peers are already light-load.

Meanwhile, the experiments also record the average process execution time. From the result we can see that the more activities the peers have, the longer the average execution time is, even when all the processes execute concurrently. It means the peer load has negative impact on process execution. In every group except for group 1, the average process execution time of experiment with load balance algorithm is shorter than the experiment with no algorithms. This status can convince us that the load balance algorithm can effectively improve the system performance.

Conclusion

This paper proposes a P2P business process execution framework for workflow management systems. After the survey on current workflow architectures, we choose P2P as our distributed architecture. The framework uses Process Migration module to handle the main work of process distributed execution. The Peer Manager and Human Task module are enhancement for process migration and execution. The scheduling experiments convince us that the distributed process execution is correct and the load balance algorithm is effective.

Our work on distributed business process execution is a first step for developing a scalable P2P workflow management system. Future work towards this object should include P2P management and scheduling framework enhancement. With these metrics the workflow system will perform better on peer management and overall execution.

Keywords: recommendation system, theatre, bipartite graph, standardization, similarity.

Abstract. Nowadays the recommendation system has been widely used, especially in the field of e-commerce, SNS, music, etc. On the basis of recommendation systems which are widely used, the paper puts forward a theatre recommendation algorithm which is more suitable in the field of theatre. In order to achieve the recommendation of theatre, the paper uses a series of steps, including weight, bipartite graph, data standardization, similarity calculation. After using this algorithm, some theatres will be recommended according to recommendation level. The results of recommendation are more reasonable, effective and satisfied.

Introduction

With the coming of internet time, a variety of data are increasing faster and faster, and thus information overload appears. It is very difficult for us to find out the thing we are interested in from a large amount of information, so the recommendation system was born. Recommendation system is to help users find some valuable information they need. Nowadays the recommendation system has been used in many fields, including e-commerce, movie, music, SNS, network, reading, ad, and e-mail.

Theatre is a place for stage performance. Due to the rising number of theatres, it is a urgent need to study how to pick out some suitable theatres from a large quantity of theatres for a specific play, however, predecessors in the field of theatre ignored it. The paper will apply the recommendation system to the field of theatre, and put forward a particular algorithm to solve the problem.

Traditional recommendation algorithms

Recommendation algorithm is the most important and key part in the recommendation system. It has a great influence on the performance of the recommendation system. At present, the traditional recommendation algorithms that are widely recognized include content-based recommendation algorithm, collaborative filtering, social network-based recommendation algorithm, and mixed methods [1].

Content-based recommendation is that, according to the objects selected by users, users get those characteristics of similar objects as recommended results. Collaborative filtering is that users get those objects some other users who share the same interests and hobbies like, or the users themselves like before. Social network-based recommendation is that users get recommended results by means of trust between interpersonal relationships.

The paper shows a theatre recommendation algorithm based on the information of the play. Because the content of the play is wide-ranging, the distinction of different plays is not obvious, content-based recommendation is not fit. Because different plays have no intersection, they don't have the same interests or the similar ones, collaborative filtering is not fit. Because the theatre has nothing to do with social network, social network-based recommendation is not fit, either. Above all, the paper puts forward a suitable theatre recommendation algorithm, combined with the traditional recommendation algorithm.

A theatre recommendation algorithm

Experimental environment. The paper mainly shows how to recommend the suitable theatres according to the information of play and something related. The information of play refers to the title of play, the type of play, the parameters of facilities about theatre (such as seating capacity, size, suspender, lighting, audio, etc.).

The paper uses the title of play, the type of play, the theatre seating capacity as three typical parameters. Through the following algorithm, in accordance with the recommendation level of the theatres, we get some suitable theatres.

Algorithm steps. Assuming the recommendation level of all theatres is 0.

Firstly, assuming the requirement of theatre seating capacity is M, Candidate quantity of the theatres is N, and the seating capacity respectively is N_i (i=1, 2, … , n). When N_i<M*0.9 (i=1, 2, … , n), the ith theatre is ruled out. When N_i>M*1.2 (i=1, 2, … , n), the recommendation level of the ith theatre adds 1, that is 0+1=1. When N_i>=M*0.9 and N_i<=M*1.2 (i=1, 2, … , n), the recommendation level of the ith theatre adds 2, that is 0+2=2.

Secondly, if the title and the type of play could be found from the historical data, the corresponding theatre recommendation level adds 1.

Thirdly, according to the historical data set, we respectively count the show number of this play type in each theatre. Assuming the show number of this play type is S, the number of theatres is N, and the show number of each theatre of this play type is T_i (i=1, 2, … , n). If F_i (i=1, 2, … , n) presents weight, we have the formula 1.

$$F_i = \frac{T_i}{S} \quad (i = 1,2,\dots,n \ \ and \ \ T_1 + T_2 + \cdots + T_n = S) \tag{1}$$

If the recommendation levels of theatres are same, the theatres rank from large to small, depending on F_i. If F_i>=0.2, the recommendation level of the ith theatre adds 1.

Fourthly, drawing a bipartite graph about the play types and the theatres to find out the professional theatres [2]. See the example Fig. 1.

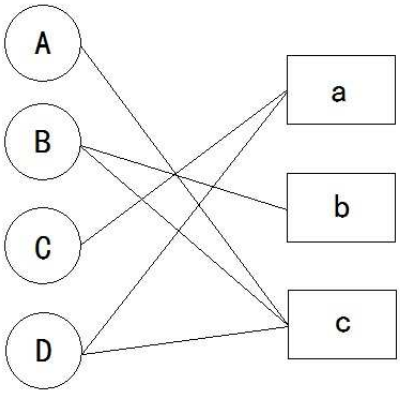

Fig. 1 An example of bipartite graph

Assuming A, B, C, D respectively represent 4 play types, and a, b, c respectively represent 3 theatres. Each link line refers that a play showed in a theatre before. Here, theatre a's in-degree is 2, theatre c's in-degree is 1, theatre c's in-degree is 3, so c is a professional theatre and c's recommendation level adds 1.

Finally, due to the show number of some big theatres is large, their ranks are relatively in the top, likewise, the show number of some small theatres is low and their ranks are relatively in the end. That is, these big theatres are likely to be recommended preferentially. In order to increase the coverage rate of the theatres, this paper uses z-score standardization [3, 4] and cosine similarity [5] to find out the suitable theatres whose historical show number is low.

Experiment and analysis

Data set. Here, the data set is from some theatre's official websites and the Internet. This experiment's data set has 500 data which include 7 theatres. The 7 theatres are *the Opera House of*

National Centre for the Performing Arts (OHNCPA), *the Concert Hall of National Centre for the Performing Arts(CHNCPA)*, *the Drama House of National Centre for the Performing Arts (DHNCPA)*, *the Opera Hall of Guangzhou Opera House（OHGOH）, the Experimental Theatre of Guangzhou Opera House (ETGOH)*, *the Opera Hall of Qingdao Theatre (OHQT)*, *the Concert Hall of Qingdao Theatre (CHQT)*. Table 1 shows the information of 7 theatres and their seating capacities.

Table 1 Seven theatres

Theatre	Seating Capacity
OHNCPA	2398
CHNCPA	2019
DHNCPA	1035
OHGOH	1804
ETGOH	443
OHQT	1600
CHQT	1200

Here, this experiment's data set include 5 play types. The 5 play types are *modern drama*, *opera*, *traditional opera*, *dance drama*, and *concert*. Table 2 shows the statistics of the show number of 7 theatres and 5 play types.

Table 2 Statistics of theatres and play types

	Modern Drama	Opera	Traditional Opera	Dance Drama	Concert
OHNCPA	0	27	0	32	5
CHNCPA	0	0	0	0	64
DHNCPA	20	12	43	9	0
OHGOH	18	30	15	61	50
ETGOH	27	0	0	0	36
OHQT	3	7	3	12	6
CHQT	0	0	0	0	20

Operation. Assuming the play title is *The Lady of the Camellias*, the play type is *opera*, the seating capacity is 1150.

Firstly, the requirement of seating capacity is 1150. We get two results through calculation: 1150*0.9=1035, 1150*1.2=1380. Compared with the 7 theatres' seating capacities, *ETGOH* whose seating capacity is 443 is ruled out. The recommendation level of *DHNCPA* whose seating capacity is 1035 adds 2, that is 0+2=2, because its seating capacity 1035>=1035 and 1035<=1380. In the same way, the recommendation level of *CHQT* whose seating capacity is 1200 adds 2. Because the seating capacities of the rest theatres are greater than 1380, their recommendation levels add 1.

Secondly, matching the play title *The Lady of the Camellias* with all the historical data, and we find out that *OHNCPA* showed this play before, so its recommendation level adds 1, that is 1+1=2.

Thirdly, calculating the weight of each theatre in accordance with the show number of *opera* in Table 2 and the formula 1, and getting the results. Table 3 shows the results of the calculation.

Table 3 Statistics of each theatre's weight in opera

	Show Number	Weight
OHNCPA	27	0.355
CHNCPA	0	0
DHNCPA	12	0.158
OHGOH	30	0.395
OHQT	7	0.092
CHQT	0	0
sum	76	1

If weight is greater than or equal to 0.2, the recommendation level adds 1. So the recommendation level of *OHNCPA* adds 1, that is 2+1=3, and the recommendation level of *OHGOH* adds 1, that is 1+1=2. The theatres order by recommendation level. If the recommendation levels are same, order by weight.

Fourthly, by calculating [2], see the following Fig. 2.

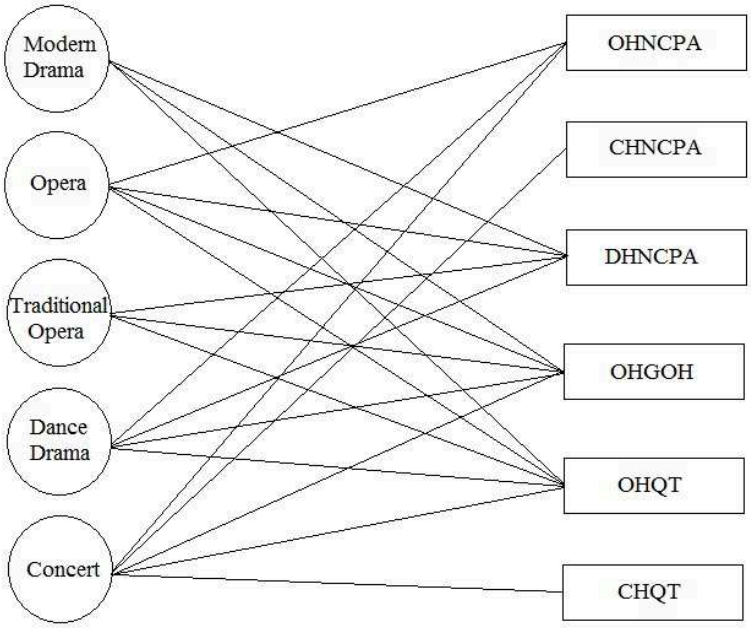

Fig. 2 Bipartite graph

Clearly, the in-degree of *CHNCPA* and *CHQT* is 1, so they are professional theatres in *concert*. However, the play type required is *opera*, so the recommendation level of this step has no changes.

Finally, finding out the suitable theatres whose historical show number is low. The theatres whose weights are greater than or equal to 0.2 are *OHNCPA* and *OHGOH*. The weights of the other four theatres are lesser than 0.2. And then calculate the similarity of the two theatres weights>=0.2 with the other theatres.

Before similarity calculation, the data standardization is needed. Because the maximum value and the minimum value of each theatre's show number are unknown, the most commonly used method of standardization min-max is not suitable. Here, z-score is used.

Z-score standardization is based on numerical mean value and stand deviation [3, 4].

See the mean formula 2.

$$\mu = \frac{1}{n}\sum_1^n x_i \quad (i = 1,2,\dots,n) \tag{2}$$

See the standard deviation formula 3.

$$\sigma = \sqrt{\frac{\sum_1^n (x_i-\mu)^2}{n-1}} \quad (i = 1,2,\dots,n) \tag{3}$$

See the z-score formula 4.

$$z(x_i) = \frac{x_i-\mu}{\sigma} \quad (i = 1,2,\dots,n) \tag{4}$$

Then use cosine similarity to calculate the similarity of theatres [5] and see formula 5 below.

$$sim(D_1, D_2) = \frac{\sum_1^n w_{1k}\cdot w_{2k}}{\sqrt{\sum_1^n w_{1k}^2 \cdot \sum_1^n w_{2k}^2}} \quad (k = 1,2,\dots,n) \tag{5}$$

Table 4 shows the results of cosine similarity calculation.

Table 4 Results of cosine similarity

	CHNCPA	DHNCPA	OHQT	CHQT
OHNCPA	-0.2816	-0.4589	0.8996	-0.2816
OHGOH	0.4229	0.7704	0.8814	0.4229

Here, assuming the threshold value of similarity is 0.8. If the similarity is greater than or equal to 0.8, it certifies the two theatres are exactly similar and two results fit which are 0.8996 and 0.8814. That is *OHQT* is exactly similar with *OHNCPA* and *OHGOH*, and the recommendation level of *the OHQT* adds 1.

Now all the operations have been finished. Table 5 shows the final results of theatres' sequence.

Table 5 Final sequence of theatres

Sequence Number	Theatre	Recommendation Level	Weight
1	OHNCPA	3	0.355
2	OHGOH	2	0.395
3	DHNCPA	2	0.158
4	OHQT	2	0.092
5	CHQT	2	0
6	CHNCPA	1	0

Evaluation. The calculation of the weights based on historical data ensures the accuracy of the forecast and users' satisfaction. The match of the play title and the seating capacity also improve users' satisfaction. The similarity calculation enhances the coverage for the suitable theatres whose historical show number is low [6].

Summary

By analyzing the theatre and play, the paper realizes a theatre recommendation system by a special recommendation algorithm in this special field, however, the paper also has some deficiencies, such as the quantity of experimental data set is few, and the effects of recommendation have no visualized digital evaluation. As a result, there are many problems needed to be solved.

Keywords: Fully homomorphic encryption, encryption, approximate-GCD problem

Abstract: Fully homomorphic encryption has long been regarded as cryptography's prized "holy grail"–extremely useful yet rather elusive. At 2010 van Dijk et al. described a fully homomorphic encryption scheme over theintegers. The main appeal of this scheme is its conceptual simplicity. simplicity comes at the expense of a public key size in$\tilde{O}(\lambda^{10})$ which is too large for any practical system. The construction is based on the hardness of the approximate-GCD problem. At 2011 Coron et al. reduced the public key size to about $\tilde{O}(\lambda^{7})$ by encrypting with a quadratic form in the public key elements, instead of a linear form. This scheme is based on a stronger variant of the approximate-GCD problem. An implementation of the full scheme was obtained with a 802MB public key. At 2012 Coron et al. described a compression technique that reduces the public key size to about$\tilde{O}(\lambda^{5})$. This variant remains semantically secure, but in the random oracle model.A level of efficiency very similar to above scheme was obtained but with a 10.1MB public key instead of a 802MB one.Coron et al. also described a new modulus switching technique for the DGHV scheme that enables to use the new FHE framework without bootstrapping from Brakerski, Gentry and Vaikuntanathan with theDGHV scheme. At present asymptotics of FHE over integers are much better.

0 Introduction

Encryption has traditionally been viewed as a mechanism that enables secure communication[1].For someone who have the secret decryption key can learn the entire message, but without the decryption key, the ciphertext is completely useless. Can we do arbitrary computations on data while it remains encrypted, without ever decrypting it? This question from Rivest et al.and then become a open problem in cryptography[2]. In a breakthrough work Gentry described in 2009 the first construction of a fully homomorphic scheme[3]. At 2010 van Dijk et al. described a fully homomorphic encryption scheme over theintegers[4]. In recent years DGHV scheme was improved continuously by Coron et al.[5][6].Asymptotics of FHE over integers are much better now.

1.The idea of fully homomorphic encryption

The first step in framework of Gentry's scheme is to describe a somewhat homomorphic scheme that supports a limited number of additions and multiplications on ciphertexts rather than do arbitrarycomputation on ciphertexts[7]. This is because every ciphertext hasa noise component and any homomorphic operation applied to ciphertexts increases the noise in the resulting ciphertext. Once this noise reaches a certain bound the resulting ciphertext does not decrypt correctly anymore. For example, the bit-size of noise is$\rho$and the threshold of noise size is$k\cdot\rho$,then the bound is reached after only$\log_2 k$levels of multiplication.

If one wants to achieve fully homomorphic encryption, the problem of noise growth must be solved. The Gentry's idea of solving it is to decrypt ciphertext, but homomorphically!The decryption circuit is inputted in the bits of a secret key and the bits of a ciphertext,each encrypted under another public key.As long as the decryption circuit can be handle by this somewhat homomorphic scheme,the output is another ciphertext for the same plaintext.If the degree of the decryption polynomial is small enough, the new ciphertext's noise would less than the old cipertext's noise; this is called the "ciphertext refresh" procedure. One can refreshciphertexts before

every homomorphic operation. So, the decryption circuitis augmented by some gate- e.g., Add; call this augmented circuit.Since AND gate and XOR gate have the property of functional completeness[8]. That is, any other logic function can be implemented by combining AND gate and XOR gate. If the somewhat homomorphic scheme can handle augmented circuits, it means it do arbitrarycomputation on ciphertexts.This somewhat homomorphic scheme can obviously handle AND gate and XOR gate. So, it is critical whether the decryptioncircuit can be handled. If it can be, this calls"bootstrapping". Unfortunately, it is not. Hence one needs to squash the decryption circuit so that the degree of the decryption polynomial is small enough. Then the somewhat homomorphic scheme can do arbitrarycomputation on ciphertexts.It means we get fully homomorphic encryption scheme.This framework has been instantiated with a number of cryptographic assumptions, yielding progressively simpler and more efficient schemes[9,10,11,12,13,14].

2.The DGHV scheme

At 2010 van Dijk et al. described the first fully homomorphic encryption scheme over theintegers. The DGHV scheme was got from a symmetric encryption scheme. Encrypt: $c \leftarrow m+2r+pq$; Decrypt: $m \leftarrow (c \bmod p) \bmod 2 = (c - p \cdot * \lceil c/p \rfloor) \bmod 2 = \mathrm{Lsb}(c)\ \mathrm{XOR}\ \mathrm{Lsb}(\lceil c/p \rfloor)$. The key is a random odd integer p.Choosing at random large q and small r. A bit $m \in \{0,1\}$. The plaintext space is a set of binary, and theCiphertextspace is a set of integers.The system as described above is obviously a somewhat homomorphic encryption scheme. Ciphertexts from above scheme are near-multiples of p. We call (c mod p) the noise associated to the ciphertext c. It is the distance to the nearest multiple of p.In order to turn it into a public key system, we take advantage of the homomorphic nature of the system. That is zero and one are also valid encryptions of themselves.

The public key is $pk=\{ x_i ; x_i=r_i+pq_i \}$. Encryption of a plaintext m is then performed by selecting a random subset S from pk, a random noise r, and outputting the ciphertext c according to: $c \leftarrow m+2r+2\sum_{i \in s} x_i \bmod x_0$.Decryption is as same as above. This is a somewhat homomorphic encryption scheme in DGHV scheme. The security of the scheme reduces to the hardness of the approximate-GCD problem. The bound of noise is set to be p/8 in DGHV scheme. In fact, p/4 or p/16 is also correct, but p/2 is not.Because computing $\lceil c/p \rfloor$ is complicated,Ecannot handlethe function $f(p,c)=\lceil c/p \rfloor$ (Does it surprise you?).Hence it makesthe decryption circuit become shallow by squashing the decryption circuit.

The main idea of the transformation is to replace c/p, which multiplies two long numbers, with the summation of a fairly small set of numbers. In termsof the bits of the addends, this summation corresponds to a polynomial of fairly low degree that the somewhat homomorphic scheme can handle. Since c is ciphertext and shouldn't be changed, we only transfer p to the summation of a fairly small set of numbers. However, p is secret key and cannot be open; p can only be hide in the summation. Hence we need a trapdoor to ensure the security of the hidden p. This trapdoor is the sparse subset sum problem (SSSP).Generate a set $y = \langle y_1,\ldots\ldots,y_t \rangle$ of rational numbers in [0,2) such that there is a sparse subset S $\{1,\ldots\ldots,\ t\}$ of size$\alpha$with $\sum s_i \cdot y_i \approx 1/p \bmod 2$ ($i \in S$). Set sk* to be the sparse subset S, encoded as a vector s $\{0,1\}^t$ with Hamming weight α. Set $pk^* \leftarrow (pk, y)$. Since $\sum s_i \cdot c \cdot y_i \approx \sum s_i \cdot z_i \approx c/p \bmod 2$, we transfer $\lceil c/p \rfloor$ to $\lceil \sum s_i \cdot z_i \rfloor$. Now the decryption circuit is converted to$\mathrm{Lsb}(c)\ \mathrm{XOR}\ \mathrm{Lsb}(\lceil \sum s_i \cdot z_i \rfloor)$. The ciphertext c* consists of c and $\mathbf{z}=\langle z_1,\ldots\ldots,\ z_t \rangle$.To see that the somewhat homomorphic scheme can handle the decryption function plus an additional gate when$\alpha$is set small enough,let us consider the computation of the sum $\sum s_i \cdot z_i$. In this sum,we have numbers $\{a_i \mid 1<=i<=\alpha\}$, each ai expressed in binary$\{a_{i,j} \mid 1<=i<=\alpha,\ 0<=j<=-l\}$ with $l=(\log\alpha)$, where at most$\alpha$of the ai's are nonzero. We want to express each bit of the output as a polynomial of the input bits, while minimizing the degree of the polynomial and the number of monomials. It can be achieved by some calculating skills. Finally,the somewhat homomorphic become bootstrappable. Then we get a fully homomorphic encryption scheme over integers.

The public key size is $\tilde{O}(\lambda^{10})$. In practice the size of the x_i's should be at least 2^{23} bits to prevent lattice attacks. The public key size is then at least 2^{46} bits, which is too large for any practical

system. The somewhat-homomorphic scheme relies on hardness of approximate-GCD. Resulting scheme relies also on hardness of sparse-subset-sum and circular security. There are two types attacks. The first consider attacks on the approximate-gcd problem for two numbers including brute-forcing the remainders, continued fractions, and Howgrave-Graham's approximate gcdalgorithm[15]. The second consider attacks for arbitrarily large values of t including lattice-based algorithms for simultaneous Diophantine approximation[16], Nguyen and Stern's orthogonal lattice[17], and extensions of Coppersmith's method to multivariatepolynomials[18]. Since the sparse subset sum problem is not well study[19], it need to study deeply.

3.Variant of the DGHV Scheme—CMNT scheme

At 2011 Coron et al. proposed some techniques in [5] to reduce the public key size and increase the efficiency of the DGHV scheme, the most important of which is to use a quadratic form instead of a linear form for masking the message when computing a ciphertext. The idea consists in storing only a smaller subset of the public key and then generating the full public key on the fly by combining the elements in the small subset multiplicatively. More precisely, ciphertexts are computed as: $c \leftarrow m+2r+\sum (b_{i,j} \cdot x_{i,0} \cdot x_{j,0}) \bmod x_0$ for $1 \le i, j \le \beta$,where$\beta$is a new parameter.Then only 2βintegers need to be stored in the public key in order to generate theβ^2 integers used for encryption.Evaluate and decrypt is same as in the original scheme, except that ciphertexts are reduced modulo $x_0$after addition and multiplication. The idea of Squashing decryption circuit is same as DGHV scheme in order to get a fully homomorphic encryption scheme. However public key is be compressed in CMNT scheme by some techniques. Generate the y_i's using a pseudo-random generator f(se) instead of storing the y_i's in the public key as in [4]. Then only the seed se and y_1 need to be stored in the public key, and the other y_i's can be recovered during ciphertext expansion by applying f(se) again. In addition, encryptions of the secret key bits should also be made available publicly so that the Recrypt procedure is simply obtained by applying the decryption circuit to the ciphertext bits and the encrypted secret key bits. Therefore one uses two bit vectors$\mathbf{s}(0)$ and $\mathbf{s}(1)$ of length$\Theta^{1/2}$ Instead of generating the secret key as a single bit vector $s=(s_1,s_2,\ldots\ldots,s_\Theta)$ .Then s is recovered on the fly during decryption as the following matrix withΘentries:$s_{i,j} = s_i(0) \cdot s_j(1)$.The encryption of the bits of s(0) and s(1) is $\sigma(0)$ and $\sigma(1)$. Finally, the secret key as sk = (s(0) ,s（1）), and the public key as pk = (pk*,se,$u_{1,1}$, $\sigma(0)$, $\sigma(1)$) .This brings down public key size to about $\tilde{O}(\lambda^7)$.

CMNT scheme is still semantically secure, but under the (stronger) error-free approximate GCD assumption. The know attacks include brute force attack on the noise, approximate-GCD attack on the public key and lattice attack on the sparse subset-sum problem.Corresponding 72 bits of security,encryption and recryption take 3 minutes and 14 minutes respectively, with a public key size of 800 MBytes.

4.Variant of the DGHV Scheme—CNT scheme

At 2012 Coron et al. describe three technologies to improve DGHV schme.

The first is a technique to reduce the public key size of DGHV-like schemes [5] by several orders of magnitude. The technology is first to generate the secret-key p. Then, use a pseudo-random number generator f with public random seed se to generate a set of γbit integersχ_i(i.e. the χ_i's are of the same bit-size as the x_i's). Finally, compute small corrections δ_i to the χ_i'ssuch that $x_i=\chi_i-\delta_i$ is small modulo p, and store only the small corrections$\delta_i$in the public key, instead of the full x_i's.Knowing the PRNG seed se and the δ_i's is sufficient to recover the x_i's.Therefore instead of storing a set of largex_i's in the public key we only storethe muchsmallerδ_i's. The new public key for the somewhat homomorphic scheme has size about$\tilde{O}(\lambda^5)$.Corresponding 72 bits of security,encryption and recryption take 7 minutes and 12 minutes respectively, with a public key size of 10.1MBytes. This encryption schemeis still semantically secure under the error-free approximate GCD assumption, albeit in the random oracle model.The know attacksis same as CMNT scheme.

The second isCoron et al. prove that the natural extension of this quadratic encryption technique to to cubic forms, and more generally forms of arbitrary fixed degree d, remains secure, making it possible to further reduce the public key size. However,this quadratic encryption technique doesn't use in the implementation. This is because the "squashed decryption" procedure adds an incompressible additional term u1 of size$\gamma = \tilde{O}(\lambda^5)$ to the public-key, so it is unnecessary to reduce the number of public-key elements x_i or the number of encrypted secret-key bits.

The third is Coron et al. show how to adapt Brakerski, Gentry and Vaikuntanathan's (BGV) new FHE framework [20] to the DGHV scheme over the integers.The new BGV framework is described in [20] with Brakerski and Vaikuntanathan'sscheme [21], and the key technical tool is the modulus-switching technique of [21] that transformsa ciphertext c modulo p into a ciphertext c' modulo p' simply by scaling by p'/p and roundingappropriately. This allows to reduce the ciphertext noise by a factor close to p'/p without knowingthe secret-key and without bootstrapping. Under the BGV framework the noise ceiling increases only linearly with multiplicative depth, instead of exponentially.However the modulus switching technique cannot directly apply to DGHV since in DGHV the moduli p and p' are secret. However we cannot reveal s in clear, so instead we provide a DGHV encryption under p' of the secret-key bits si, as in the bootstrapped procedure. Then the expanded ciphertext can be collapsed into a new ciphertext $c''=2\langle\boldsymbol{\sigma},c'\rangle+[c]_2$ under p' instead of p, for the same underlying plaintext. Corresponding 72 bits of security, encryption and recryption take 3seconds and 2hours 27 minutes respectively, with a public key size of 18MBytes.The running time of the Recrypt operation is disappointing compared to the non-leveled implementation; however we think that there is room for improvement.A leveled fully homomorphic scheme include the bootstrapping operation; although not strictly necessary, this enables to get a FHE that canperform homomorphic evaluations indefinitely without needing to specify at setup time a bound on the multiplicative level.

5. Conclude

We describe the progress of fully homomorphic encryption over integers. The result shows fully homomorphic encryption over integers is not only conceptual simplicity but also asymptotics are much better now. We think the high efficientmethod is similar tothemodulus-switching technique should be to study in fully homomorphic scheme over integers. Moreover, we think, the running time of the Recrypt operation in the leveled implementation, there is room for improvement.

Keywords: latent semantic indexing; agricultural knowledge; questions and answers system

Abstract: In this paper was proposed to use latent semantic indexing technology in agricultural knowledge questions and answers system in accordance with the current condition of agricultural knowledge resources in JILIN province and the problems existing in the agricultural knowledge questions and answers system and professional work process. This technology can enhance or reduce the influence on the semantic in the document and can more clear the semantic relationships, retrieve the natural language to some extent, eliminate the interference from identity and polysemantics and obtain better search results.

1. Introduction

With the rapid development of computer technology, agriculture as a basic industry, is an integral part of social information, so agriculture is bound to be a computer network technology, multimedia technology and intelligent features of the information technology wave of the baptism. Currently more and more variety of agricultural information network for agricultural scientists and farmers use, they often search using various search engines of agricultural information. Since search engines are not designed for the agricultural sector, most search results are often unable to meet their needs, Agriculture Question Answering System is in this case developed. Knowledge of the system of agriculture is agriculture-related field of agriculture user input natural language questions, it is able to give a concise, accurate and user-friendly answer. Is a comprehensive use of various natural language processing technology, new agricultural information retrieval system.

From a large number of agricultural information quickly and accurately obtain the information most needed is the development of agricultural knowledge question answering one of the difficulties. How to make existing information resources in Jilin Agricultural fully utilized effectively to improve the Jilin Province, the quality of agricultural information services, staff of agricultural research has become a hot spot. Latent semantic indexing, is the gradual rise in recent years, the search is different from the keyword search engine solution, the practical effect of its search results closer to the natural language, to a certain extent, improve the relevance of search results, has been gradually applied to the library, database and search engine algorithms were.

Latent semantic indexing is an extension of the vector space model, the concept of using statistical calculations to find out the index information retrieval, rather than the index of words, words. Latent semantic indexing based on the existence implied in the document library on the word, the word used in semantic structure, a portion of this semantics as the semantics of a document or masked by the diversity of form and not very obvious. Latent semantic indexing is through the words of the original document library - documents created by singular value decomposition of the matrix calculation, and then whichever is the former k largest singular value, then the corresponding singular vectors to form a new matrix, with its approximate expressed that the original word document libraries - document matrix. Because the new matrix reduced the semantic relations between words and documents ambiguity, so this method is more conducive to information retrieval.

2. The basic principles of latent semantic indexing

Between the text and vocabulary because there is a certain correlation, so the number of articles a number of words from the text and the correlation between them constitute the semantic model; use

mathematical algorithms and computer technology to analyze this model and its computing and processing, keep the main text and the correlation between words, remove the other redundant, secondary factors, such models have been optimized; the final form of the semantic structure and the original text, terms related to compare the structure and scale to much smaller, and also retains one of the major correlation with the model text and vocabulary mining implicit relations; in the upcoming search, the use of the semantic structure as a basis, the statistics of the implied terms and the correlation between the text .

In vector space, each document can be represented as a vector space vector word Di = (wi1, wi2, ..., wim) (T1, T2, ..., Tm) T, so that each entry documents also can be expressed as space vector Tj = (w1j, w2j, ..., wnj) (D1, D2, ..., Dn) T, between the entries and the entries using vector cosine similarity to calculate.

In the latent semantic indexing algorithm, a document library can be expressed as a m × n word, document large matrix A. Where n indicated the number of documents in the library, m that contains all of the library the number of different words. Each line of the matrix A corresponds to a different word, each column of matrix A corresponds to a document. A is expressed as:

$A = [aij], 1 \le i \le m; 1 \le j \le n$

Aij is the element in the feature item in the document Dj Ti or the frequency of emergence weight. Practical applications, because the number of words and documents may be very large, the word appears in a single document and very limited, so A is generally higher in the sparse matrix.

At this time the use of vector algebra proof that the relevant knowledge, matrix A can be decomposed into three matrices, namely:

$A = U\Sigma VT$ (1-1)

Where the diagonal matrix Σ that matrix, the matrix A is the diagonal singular value of the element. Matrices U and V are orthogonal column vectors normalized. U is the m × r "left singular vector matrix"; V is r × n of the "right singular vector matrix", r is the rank of matrix A and are:

U = VT V = In (In the n-order unit matrix)

A matrix decomposition [4] shown in Figure 1.

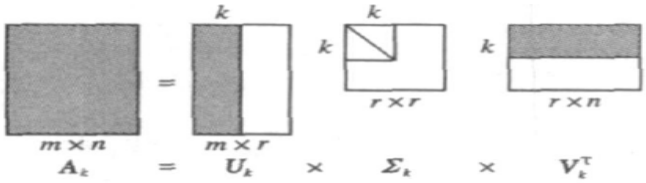

Figure 1 Schematic diagram of singular value decomposition

The diagonal matrix of singular values Σ descending order, the matrix of the first k diagonal elements were retained, the rest set to 0, while taking matrix U and matrix V in the front row constitutes a k-approximation matrix A Ak the rank K. So that you can get a new approximate decomposition matrix Ak:

Ak = Uk × Σk × VTk

Uk Vk matrix column vector and matrix are orthogonal vectors. So we can use Ak approximated the original term document matrix A, matrix and matrix Vk Uk row vector, respectively, in the words and documents, in this decomposition method, based on further knowledge related to agriculture or other document retrieval kinds of document processing. This is based on latent semantic indexing of Jilin Agricultural Knowledge Q & A basic idea of the system.

Although the latent semantic indexing is included in the document the words to express the semantic content of the document, but the latent semantic indexing algorithm, the concept of the reliability of the document with the document can not be fully expressed in words. Because of the diversity of words in the text, to a large extent overshadowed the relationship between words and documents, latent semantic index of the original document through the vector matrix of the singular value decomposition, taking the k-order approximation of the decomposed matrix This first cut of the original word document matrix contained in the "noise" such as synonyms, the words and semantic relations between documents is more protruding; the second is to make the word of the

document vector space dimension of greatly reduced, thereby can increase the efficiency of agricultural knowledge of the document retrieval.

3. Based on the Chinese text retrieval system LSI

Latent semantic indexing based question answering system of agricultural technology sub-five steps to retrieve the main steps, namely:

1) words, the establishment of the document vector matrix A;

Using non-dictionary word segmentation algorithm, the text of the library entries in the segmentation and word frequency statistics, the establishment of a word document library, document vector matrix A, and its normalized;

2) The singular value decomposition;

The establishment of the matrix A by the method described above singular value decomposition to obtain a matrix Vk, Vk matrix corresponding to each row in the library of all documents;

3) the query vector of the projection;

The query vector projection to get the equivalent transform k-word document matrix, the matrix Vk is the vector of the line;

4) similarity calculation and measurement;

Vector distance formula or the vector used cosine similarity formula, according to the degree of similarity between vectors, find the most similar with the query result set, ordered by descending value of similarity, and similarity greater than a value return document;

5) repeatedly to find, until satisfactory results

The satisfaction of the query results, and if not then spend time to transform the query results and re-locate the most similar document, this process can be recycled, until satisfied.

On latent semantic indexing techniques and classification techniques commonly used to compare the accuracy, experimental results show that the former is significantly better than the latter, because the latent semantic model to some extent, weakened or eliminated each class The noise in the vocabulary. However, latent semantic indexing technology is still not handle the full semantics of the text, so that the performance in some applications than commonly used classification algorithm, it requires a deeper semantic algorithm research. For the whole text classification, latent semantic indexing technology to overcome many shortcomings of traditional models, in many applications have achieved good results, shown in Figure 2.

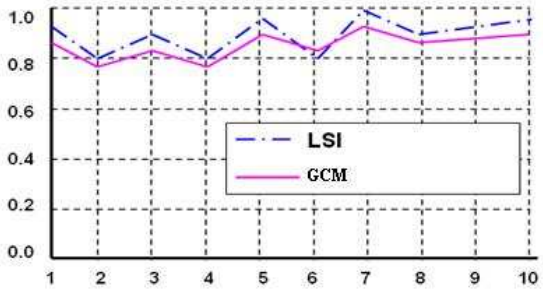

Figure 2 Classification accuracy comparison

4 Conclusion

Agricultural Knowledge Q & A system is a comprehensive, complex system that involves many technical aspects of information processing. As the complexity of agricultural knowledge and particularity of the past, information retrieval technology is difficult to solve the information in the synonymy and polysemy problems. In this paper, the new information retrieval method - LSI to introduce the system of agricultural knowledge quiz, question answering system for the retrieval of agricultural knowledge presents a new way of thinking and processes. Experiments show that this technique shows significant performance advantages, effective solution to the noise data on the classification of the negative impact brought about to raise a question and answer questions the accuracy of the system.

Creating a new combined influence measure: an analysis of the citation network

Rui Deng

School of North China Electric Power University, Baoding, 07100, China

rui-yo@163.com

Keyword: Influence measure, network science, citation network

Abstract. This paper utilizes social network analysis to create a comprehensive evolution system to determine the significance of research papers. Citation network was analyzed from H-index, Impact factor and relative citation rate, which indicates the influence of the author, published journal and the paper on the field respectively. Influence citation network was built visually though transforming the 16 science network paper's citation multi-value matrix into two-value matrix in UCINET and by analyzing those influence measures, the scores of each paper were calculated and results maps through visualization. The results concern: the paper of Collective dynamics of `small-world' networks laid a foundation on network science. Besides, a general methodology is provided to determine the role or influence measure of academic journals.

Introduction

One of the techniques to determine influence of academic research is to build and measure properties of citation networks. Citation a manuscript usually connotes a strong influential connection between researchers. In order to measure such influence, there are network-based evaluation tools that use data to determine impact factor of researchers, publications, and journals. Some of these are Science Citation Index, H-index, Impact factor.

We want to further discuss the relation structure of research papers on network science, and take the citation relations of core paper on network science as a social network, to see which paper lay in the center, which lie in the margin of this network. This paper attempts to utilize social network analysis to disclose the relation of core papers. We will provide a general methodology to determine the role or influence measure of an individual network researcher.

Data and method

Data. Network science is a new, emerging, diverse, interdisciplinary field so there is no large, concentrated set of journals that are easy to use to find network papers even though several new journals were recently established and new academic programs in network science are beginning to be offered in universities throughout the world. I collected related paper data for those publications from the Science Citation Index (SCI) and the Social Sciences Citation Index (SSCI) compiled by the Institute for Scientific Information (ISI), because SCI and SSCI are two of the best sources of citation data. I used Web of Science, which is a Web-based user interface for ISI's citation databases, as well as Google Scholar Search. The table below is a listing of possible papers that could be included in a foundational set of influential publications in network science. I use these papers to analyze and develop a model to determine their relative influence.

Table 1 Set of research papers on Science Network

At first, I develop the citation network matrix which indicate the relationship among those papers and visualize the network by applying the UCINET, network analysis software. To make the network clear, we define:

paper node *v* cites node *i* paper node *i* cites node *v*

Figure 1 The Direction of Citation Relationship

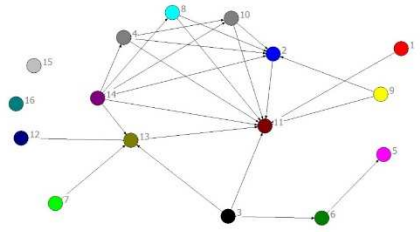

Figure 2 Citation Network

Method. In order to compare the significance of each research paper, firstly, three influence factors explored related to the research paper were and the data was collected respectively; then I develop an influence measure model of research paper and illustrate the analyzing procedure schematically in figure 3. At last, a general algorithm to determine the role or influence measure of academic journals is provided.

Influence factors

H-index (HI)

The H-index is an index that attempts to measure both the productivity and impact of the published work of a scholar. The index is based on the set of the scientist's most cited papers and the number of citations that they have received in other publications. From *Web of Science*

Impact Factor (IF)

The impact factor of an academic journal is a measure reflecting the average number of citations to recent articles published in the journal. It is frequently used as a proxy for the relative importance of a journal within its field, with journals with higher impact factors deemed to be more important than those with lower ones. From *http://www.medsci.cn/*

Citation Rate(CR)

The Citation Rate is the times of a paper being cite which reflect its influence directly in the field of academic. By exploring the references of each paper, we can list the citation rate in the set of paper. Specifically, after analysis the dataset, we determined the degree of network nodes to measure level of concern outside. From *http://scholar.google.com*

Model. Based on the previous analysis, the citation influence model is developed which illustrate the influential research paper form different parts. The method is below.

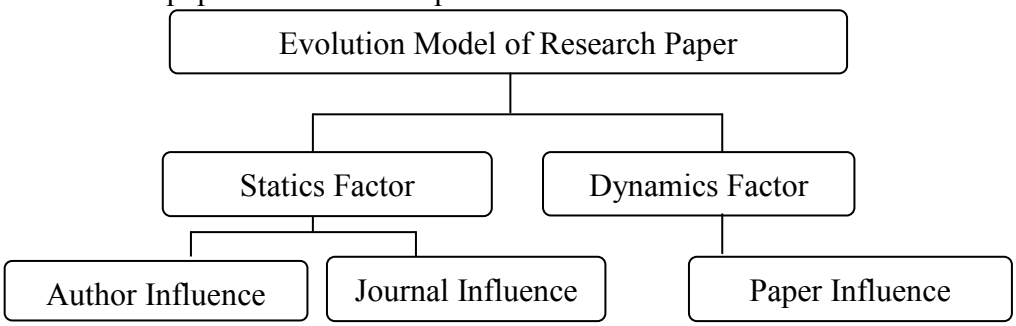

Figure 3 The evaluation influence model

Computation of Static Influence(SI). Considering that the size of the network might change, to compare the centrality
of different graph, normalized measure can be derived:

$$SF(i) = IF(j) + HI(i) \tag{1}$$

$$IF(i) = \frac{IF(i) - \min[IF(j)]}{\max[IF(j)] - \min[IF(j)]} \tag{2}$$

$$HI(i) = \frac{h(i) - \min[h(j)]}{\max[h(j)] - \min[h(j)]} \tag{3}$$

Where SF represents the inherent influence in the citation network, $IF(i)$ represents the impact factor which the paper i published in, $HI(i)$ represents the H-Index of the author.

Computation Dynamic Influence (DI). We choose the type of influence measure to compare the significance of a research paper by analyzing the important works that follow from its publication. In the citation network, we use the papers cited rate to weigh the relative importance of the paper. The measure can be written:

$$DF(i) = \sum_{i=1}^{16} d_{ij} \times f_i \tag{1}$$

$$f_i = \frac{\sum_{i=1}^{16} d_{ij}}{\sum_{i=1}^{16}\sum_{j=1}^{16} d_{ij}} \tag{2}$$

$$DF(j)=\frac{c(j)-\min[c(i)]}{\max[c(i)]-\min[c(i)]} \quad (6)$$

Computation Overall Influence (OI). Taking all kind of measures to be considered, we define the overall influence as the OI to compare the significance of a research paper. The measure can be written:

$$OI(i)=SF(i)+DF(i) \quad (3)$$

Results and discussion

Results. After the analysis of the citation network, we listed the inherence influence and dynamic influence score. Finally, we give the overall influence score of the 16 paper.

Table 2 Four Measure Scores

Paper Title	HI	IF	CF	**OI**
Collective dynamics of `small-world' networks.	0.33	0.74	1	**2.08**
Identity and search in social networks.	1	0.61	0	**1.61**
Statistical mechanics of complex networks.	0.37	1	0	**1.37**
Emergence of scaling in random networks.	0.37	0.61	0.3	**1.28**
Navigation in a small world.	0.19	0.74	0.1	**1.03**
The structure of scientific collaboration networks.	0.6	0.18	0.1	**0.88**
Scientific collaboration networks: II.Shortest paths, weighted networks, and centrality.	0.6	0.04	0.1	**0.74**
The structure and function of complex networks.	0.6	0.11	0	**0.71**
Power and Centrality: A family of measures,	0.19	0.11	0.3	**0.59**
On properties of a well-known graph, or,What is your Ramseynumber?	0.19	0.1	0.2	**0.48**
Networks, influence, and public opinion formation.	0.4	0.06	0	**0.46**
Models of core/periphery structures.	0.37	0.06	0	**0.43**
Identifying sets of key players in a network.	0.3	0	0	**0.3**
Statistical models for social networks.	0.19	0.09	0	**0.27**
On Random Graphs,	0.19	0.08	0	**0.26**
Social network thresholds in the diffusion of innovations,	0.19	0.06	0	**0.24**

Discussion. We compare our results in the table, we can easily find the paper named *Collective dynamics of `small-world' networks* is the most significant work. Besides, the author of this paper is the pioneer in the field of Science Network Analysis.

Conclusion

The influence of academic journals is based on the academic background and the creativity, the influence in society as well as the influence of the reflected recognition readers a comprehensive effect. To investigate the academic journals influence in the same field, we can also use the Evolution model. The calculation procedure is as follows:

Step1:Dataset Collection and Extraction

First, choose a set of journals and collect the number of literatures included in the journal respectively Then, search for the each journal retrieval system or database income data; At last, count the recitation rate inside and outside of the each journal.

Step2:Build the analysis network

Take the self-cited rate as the value of the correlation matrix diagonal from the journals and the links value as the rest of the matrix. Then, we will obtain the incidence matrices. At last, by the software UCINET6, draw the network of the journals citation network.

Step3：Comprehensive Assessment

Compute the inherent influence and dynamic influence by applying the network centrality. Then, calculate the overall influence sore and ranking journals. At last, we can obtain the most influential journal.

This paper represents a comparative study to investigate the performance of research paper for detecting emerging research fronts among citation networks. A case studies in a science network research domains with 16 important papers. After citation networks were constructed, papers were explored in three different aspects using those measures of Science Citation Index, H-index, and Impact factor. By using the weight based on the frequency of citations, the influence of the paper is detected. By using the weight based on the H-index, we can see the impact of the published work of a scholar. By using the weight based on impact factor shows the relative importance of a journal within its field. We develop the comprehensive evolution system and evaluated the visibility, defined as overall scores, determining the significance of the research paper or academic journals. This general methodology can applied into other academic field to compare their relative influence.

Keywords: OpenFlow; Load balancing; Fat-tree; Mininet; POX

Abstract. Cloud services have been explosively popular over the last decade. And data centers play an essential role in providing cloud services. Inside a data center, any server instance has the chance to inject traffic of various applications into the network. Yet how to balance the enormous internal load to make the best of data center network is a highly prioritized problem to be solved. To provide balanced traffic in data centers, this paper proposes an OpenFlow-based GLB load balancing algorithm in data center fat-tree networks. GLB uses a path-related weight to select path. This weight indicates how balanced of a path. We implement GLB algorithm as a module in an openflow controller platform, POX. On the self-defined modified mininet emulation platform, we conduct experiments in a fat-tree topology environment running random traffic to generate performance data. Experiment results demonstrate that our proposed GLB algorithm outperforms DLB algorithm in terms of load balancing.

Introduction

With the spring of Cloud service, data centers have become the vital infrastructures that Cloud service providers focus on. Inside a data center, any server instance has the chance to inject traffic of various applications into the network. Therefore, how to balance the enormous internal load to make the best of data center network is a highly prioritized problem to be solved.

Fat-tree [2], a special instance of Clos topology is adopted in data center networks to lower the cost of building such a network and provide multiple paths between any two hosts. A k-ary fat-tree is consisted of k pods and each pod have two layers of k/2 switches. The k-port switches in the edge layer are directly connected to k/2 hosts and the other k/2 ports are connected to k/2 ports of the aggregation layer switch. The hierarchy has $(k/2)^2$ k-port core switches and each of them has one port connected to each of k pods.

Load balancing is to adjust the load of system dynamically, so as to make the load of each node closer. Load balancing in networks usually use dynamic algorithm to distribute traffic load between different links. Traditional load balance solution can be divided into two types:

Software-based solution is simple and cost lower and the configuration of software solution is flexible, but it needs more time to deal with the load. And the software may be the bottleneck of the system. Hardware-based approach is faster but it also cost more. And it also needs proprietary hardware without much flexibility, and may be the single point of failure in the network.

OpenFlow [6] derives from a research project in Stanford. It decouples control plane from legacy switches into a centralized controller, which instructs switches what to do with received packets by installing flow table entries. OpenFlow takes advantage of both software and hardware load balancing. With commodity OpenFlow switches, OpenFlow provides line-speed forwarding performance, improved security with SSL, flexibility and reusability with programmable hardware.

In this paper, we propose GLB (Global Load Balancing) algorithm. GLB generates a weight based on current available bandwidth of each link along the path. This weight represents how balanced of this path. When selecting path, simply pick up the path with highest weight. We implement GLB as a module in the POX [7] controller platform. On the self-defined modified mininet [8] emulation platform, we conduct experiments in a fat-tree topology environment running random traffic to generate performance data. We evaluate our algorithm by average bandwidth ratio, average packet delay and link load jitter. Experiment results demonstrate that our proposed GLB algorithm outperforms DLB algorithm in terms of load balancing.

Related Work

In this section, we introduce a typical data center network topology, that is, fat-tree topology. We also present other openflow-based load balancing research. Since the characteristics of openflow such as decoupled control plane and flexible network configuration are very suited for providing load balancing service, there already exists some research work that combines openflow technology with load balancing.

Plug-n-Serve system, presented in [3], tries to minimize response time by controlling the load on the network and the servers using customized flow routing. The system utilizes up-to-date status of the network and adapting to current load conditions to dynamically reschedule network requests. But this system is for campus network. It doesn't consider data center networks. [4] proposes an innovative openflow-based load balancing mechanism that supports multi-service. For each different service traffic in the network, there is a separate controller respectively.

For example, one controller handles the standard network trafffic between the server nodes, while another controller handles the load-balancing of the web-servers and another one the load-balancing of video streaming servers. Yet it's not specifically aimed at data center networks, which have different traffic distribution needed to be well handled. [1] introduces a DLB (Dynamic Load Balancing) algorithm aiming at data center networks. DLB is an openflow-based load balancing algorithm that fits into data center network topology . This algorithm exploits depth-first method, picking up the best link on every hop, trying to end up an overall best path. In [1], DLB is compared with other two load balancing algorithms: hash-based randomized path selection NLB (None Load Balancing) and location-based SLB (Static Load Balancing). The results show that in fat-tree topology networks DLB provides higher average bandwidth ratio and shorter average packet delay than the others. Still, this greedy path selecting policy doesn't count for overall link load distribution in the network and may leads to a local best path.

Algorithm Design and Implementation

In this section, we illustrate our GLB algorithm design and implementation.

Algorithm Design

In this paper, we propose an openflow-based load balancing algorithm, that is, GLB. GLB pre-stores all possible paths between every two hosts in the network into a path set $\{Paths\}$:

$$\{(Host_{src}, Host_{dst}): \{Path_1, Path_2, \cdots, Path_i\}\}$$

For each complete path in the Paths set, GLB calculates a path weight W_{path}:

$$W_{path} = \overline{linksBw}/\sigma_{linksBw} \quad \text{(Eq. 1)}$$

$\overline{linksBw}$ is the average current available bandwidth Bw_i of each $link_i (1 \le i \le n)$ in $Path_i = \{link_1, link_2, \cdots, link_n\}$:

$$\overline{linksBw} = \frac{\sum_{i=1}^{n} Bw_i}{n} \quad \text{(Eq. 2)}$$

The value of W_{path} is growing along with the increment of $\overline{linksBw}$, indicating that average available link bandwidth is higher than any other paths.

$\sigma_{linksBw}$ is the standard deviation of available bandwidth of every link along the path:

$$\sigma_{linksBw} = \sqrt{\frac{\sum_{i=1}^{n} (Bw_i - \overline{linksBw})^2}{n}} \quad \text{(Eq. 3)}$$

The decreased value of $\sigma_{linksBw}$ leads to the elevated value of W_{path}, meaning that difference between available bandwidth of every link is lower and that odds of certain link bottleneck caused congestion are smaller.

W_{path} will be updated as link statistics gets updated. So the real-time link quality could be reflected.

Instead of single-hop best link path selection policy, GLB chooses a complete path based on the path weight, which reflects load of every link along the corresponding path.

Given $Host_{src}$ and $Host_{dst}$, GLB algorithm process is presented in Fig.1:

Algorithm GLB Path Decision Algorithm

Require: Flow(srcHost, dstHost), paths

```
1: PathDecision(){
2: srcEdge = FindEdgeByHost(srcHost)
3: dstEdge = FindEdgeByHost(dstHost)
4: topLayer = GetTopLayer(srcEdge, srcEdge)
5: if topLayer == edgeLayer then
6:     return srcEdge
7: end if
8: candidatePaths = paths.Get(srcHost, dstHost)
9: return BestPath(candidatePaths)
10: }
```

Figure 1. Algorithm Process of GLB

GLB first calculates the highest level switch need to access, according to the source host and the destination host. If source and destination host connect to the same edge switch, algorithm directly return this edge switch as selected path. If the highest level reaches aggregation or core switch, GLB will look up all candidate paths by tuple key ($Host_{src}$ and $Host_{dst}$ in the path set {Paths}. Then GLB choose the path with highest W_{path} as the output of the algorithm.

Algorithm Implementation

Our proposed GLB algorithm is implemented as a module named LoadBalancer in POX [7] controller. This module contains two self-defined components, which are PortStatsMonitor and FlowDispatcher. A built-in topology discovery component is also loaded to provide nodes adjacency information.as reference.

As a module of POX, LoadBalancer is responsible for two main functions: monitor port traffic statistics and schedule flows with no matching flow entries.

1) PortStatsMonitor
   Our algorithm require latest available bandwidth of each link. Yet this information cannot be directly retrieved from both switches and controller. In our implementation, PortStatsMonitor component periodically inquires all the switches about ports statistics, calculates transmitted bytes on every port during this interval and consider incremented bytes as the measurement of link available bandwidth. We define a monitoring cycle T. Every start of T, component sends OFPT_STATS_REQUEST openflow message with type OFPST_PORT to all switches, demanding an OFPT_STATS_REPLY message. When receiving port statistics reply message, component calculates incremented bytes in the cycle T as the link load info. Then, component finds all links that this port participates and update link load info. After updating link load info, component should refresh W_{path} of each path in $\{Paths\}$.
2) FlowDispatcher
   An OpenFlow switch maintains a flow table. On receiving a packet, switch matches packet header and incoming port number with flow entries in the flow table. If match succeeds, packet will be handled according to the action field of the matched flow entry. Otherwise, switch buffers the packet with a buffer ID and send a Packet-In message with this ID to POX. As a component, FlowDispatcher would process this Packet-In message and then select the best appropriate path. It's a list of switches needed to traverse from source host to destination host. FlowDispatcher then converts determined path into a series of FlowMod message targeting on switches along the path. At last, component installs flow entry along the path by sending these FlowMod messages to build up the path.

Evaluation

In this section we define our measurement methods, specify our environment setup and reports our performance study for the proposed GLB load balancing algorithm and DLB load balancing algorithm.

Measurement Method

1) Average Bandwidth Ratio
A flow's designed bandwidth is the bandwidth at which Iperf client sends UDP flow. A flow's actual bandwidth is the bandwidth that Iperf server actually receives at. Due to network congestion caused packet loss or possible transmission error, a flow's actual bandwidth is less or equal to its designed bandwidth. Average bandwidth ratio φ is the average ratio of every flow's actual bandwidth and designed bandwidth, as in Eq. 4.

$$\varphi = \sum_{i=1}^{n} \frac{actual\ bandwidth\ of\ flow_i}{designed\ bandwidth\ of\ flow_i} \Big/ n \quad \text{(Eq. 4)}$$

Average bandwidth ratio relates to the extent of load balancing in the network, the higher Average bandwidth ratio, and the more balanced network gets.

2) Average Packet Delay
Packet delay μ is defined as the duration from the time packet sent out in the client to the time received by the server, as in Eq.5.

$$\mu = \frac{\sum_{i=1}^{n} t_{i-server} - t_{i-client}}{n} \quad \text{(Eq. 5)}$$

3) Link Load Jitter
Link load jitter Δ is defined as follows: in unit interval T, the standard deviation of load of all links in the network, as in Eq.6.

$$\Delta = \sigma(linkload) = \sqrt{\frac{\sum_{i=1}^{n} (load_{linki} - \overline{load_{links}})^2}{n}} \quad \text{(Eq. 6)}$$

$\overline{load_{links}}$ is the average load of all links.
For all the links in a network, higher link load jitter indicates that link load distribution deviates more from the average link load and that traffic loads are more unbalanced, vice versa.

Traffic load, serving as the variable in the experiment, is defined as the ratio of occupied bandwidth and total bandwidth on links between hosts and edge switches. We tested 9 groups with traffic load ranging from 0.1 to 0.9.

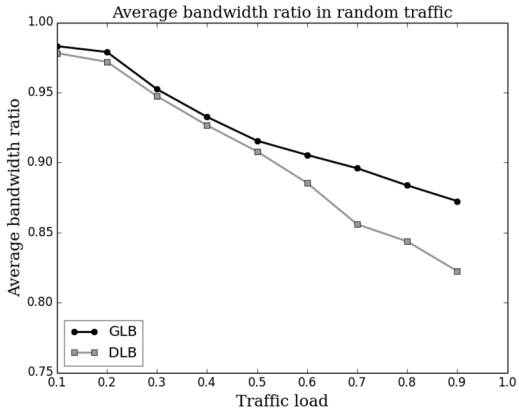

Figure 2. Average bandwidth ratio in random traffic

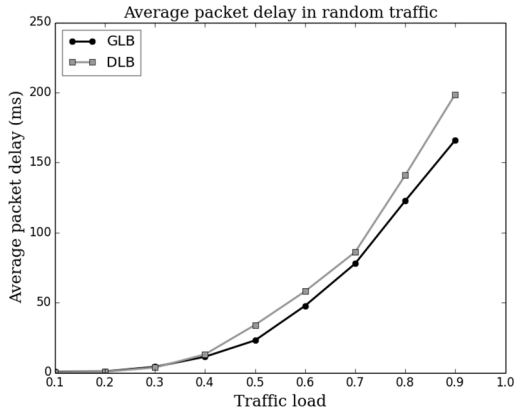

Figure 3. Average packet delay in random traffic

Environment Setup

We build a self-defined 8-ary fat-tree topology environment on Mininet emulation platform. POX controller runs with our implemented LoadBalancer module. Mininet and POX get running on different PCs so as to reduce the CPU usage. We use Iperf tool to generate random traffic pattern [5] between any two hosts in the fat-tree topology.

Results

After running experiment, we analyze reports generated by Iperf servers. Results are as follows:

From fig.2, we can see that average bandwidth ratio of both algorithms decrease as the traffic load rises. GLB has a better performance in terms of average bandwidth ratio than DLB, especially after traffic load reaches 0.6. This is probably because under heavy load circumstances DLB is more likely to cause network congestion by choosing local best link, raise packet loss rate and lower average bandwidth ratio. While GLB bases global load information to select path, making it less possible to cause congestion.

Fig.3, shows average packet delay in random traffic. Generally average delay changes more radically than average bandwidth ratio. GLB outperforms DLB on packet delay attributed to global path choice, which lower the probability of congestion. When the load reaches 0.9, packet delay of both algorithms exceeds 150ms. This fact implies that when hosts send flows at nearly its maximum bandwidth, most links in the network are busy, packets have to wait longer in the queue of switches.

Conclusion

This paper focuses on the load balance issues in data center fat-tree topology networks. It analyzes the existing studies of OpenFlow-based load balance, and points out the defects of single hop greedy routing policy that is from the DLB algorithm proposed [1]. Based on the aforementioned analyses, this paper present the GLB algorithm that overall considers the current available bandwidth of each link in the whole path and selects the links with respect to their weights. Then, the proposed GLB algorithm and its load balancing module are both realized on the POX controller platform. In addition, the user-defined fat-tree topology environment is established on the Mininet simulator and the random traffic scenario is adopted in the experiments. The experimental results have shown that the proposed GLB algorithm achieves better performance in load balancing of data centers using fat-tree topology as compared to the benchmarking DLB algorithm.

In future work, we plan to re-evaluate the effectiveness of the proposed algorithms by using more precise data center traffic patterns generated by [9].

Keywords: cloud computing; digital library; cloud services platform

Abstract: The Digital Library has begun to enter the cloud computing era after experienced the Internet era, This paper constructed a cloud services plat form of digital library based on cloud computing technology, then described the service processes and the operating mechanism of the digital library cloud services plat form.

With the development and progress of various computer, network, and information technology, the concept of networks, digital and virtual libraries have appeared, and their substance have no difference, just the perspective of observing and understanding is different. For digital libraries, there is no uniform definition, but it can be described as that digital library is a service system through combining computer and communication technology under the network environment, that organize, integrate and manage effectively for the user. Essentially, digital library is still an information resource system, but it is different with the traditional library, for example, digital libraries are used to save some of the country's rare and precious books and other valuable data in digital form; Facilitating saving and difficult to wear the information resources; Facilitating information resources sharing; Facilitating information retrieval for the information users. But digital library also facing difficulties, first is that digital libraries are faced with the dilemma of technology, which makes information resources stored issues become the biggest problem. So the technology of image retrieval, multi-language retrieval, data exchange between different data standards, human-computer interaction technology, then software and tools which needed by digital libraries, all of these have to be improved and further developed. Besides that massive resources lead to the limited data management, backup, and storage capacity also presents a challenge to the digital library. Secondly, the digital library is facing a dilemma with the growing information needs of information users. Although Digital Library makes Library Services breaking the original space constraints, and the traditional library services can be extended, the information users' increasing demand for continuity, personalization, diversity and timeliness of the information service require digital library to provide with better information services[1].

2. Construction of the Digital Library Service Model

The framework of the design of libraries cloud service centers, presented by this paper, is based on the support of infrastructure layer , which providing an open platform(developmental environment) as well as software services.

2.1 IaaS Layer (Infrastructure Layer)

Infrastructure layer is the foundation of the entire cloud service center to support the operation, it consists of a cluster of servers, storage devices,network communications facilities. There are two major sources of these resources: First is the local library resources , the second is the resources bought from the cloud computing service providers. The physical location of these resources are scattered, we only need to use virtualization technology to change physical resources into logical resource which can be managed, that kind of technology can virtual these sources into a pool of resources, and then make the resources in the resource pool for unified deployment.. Virtualization

technology enables the deployment environment and the physical platform independent, which makes the local library's resources can be well integrated with the newly purchased resources of cloud computing service providers , then managed through the virtual platform and continue to expand, migrate and copy based on changes in demand. Resource pool will form multiple isolated virtual private servers , where each virtual server can run independently with separate root access , IP addresses , memory, files, system libraries function and configuration files. With this technology, cloud service center provide users with more and more competitive services, and safe, stable environment. The function of resource pool is to provide computing and storage resources needed for the various applications. Managing the computer processor and memory virtually by the way of resource pool can greatly improve the resource utilization. The aim of infrastructure layer, which use a virtual storage to formed a unified management of a variety of storage devices in a storage pool, is to provide users with the storage system of high data transmission capacity [2]. Further, the virtual storage can also reduce the cost and complexity, and to achieve unprecedented flexibility and choice, so that the efficient flow of information can be extended to the outer boundary of cloud services, improving horizontal collaboration and communication in order to promote efficient growth of computing services.

2.2 PAAS Layer (Platform as a Service)

Through solving the problem of storage capacity and computing efficiency virtually of cloud service centers, infrastructure layer become a support for the center of cloud services, just like a giant supercomputer floating in the clouds. PAAS layer is a system built on the infrastructure layer, managing, monitoring, applying to infrastructure, which called as “huge super computer”. PAAS layer provides management and services through serving for middleware to communicate with the infrastructure layer. The basic function of the PAAS layer is to standardize and operate the identify, authentication, authorization, directories, security and other services by hiding the underlying hardware, operating systems and network heterogeneity, which provides a unified standardization program interface and protocol for application, in order to achieve a unified management of the network resources. Its user management covers user authentication, user license, and user customization. And resource management covers load balancing, resource monitoring, failure detection, etc. Security management covers authentication, access authorization, security audit, comprehensive protection, etc. Image management covers image creation, deployment and management [3]. In addition, the PAAS layer will build a open platform for application. The realization of this platform is to open the application programming interface or function through the software system of the PAAS layer, which in order to increase the function of the software system of the PAAS layer and use the resources of the system. Open application platform will not only provide open interfaces for the providers of third-party computing software services, but also for the native libraries and end-users. Through this open interface, first for a authentication, only the local libraries of the alliance and their users, as well as the third-party cloud computing software service provider can be tested and verified. After verification, third-party service provider can add their own application software systems embedded in the platform, and these software systems will be rent by users’ payment. After authenticated, users are able to query the required services in the service catalog, and have the access to these services, that is to say, it is a way by using a variety of software systems to meet their service needs, which users have to pay or share the platform layer. What’s worth mentioning is that open with sharing is the features of the open application. As long as the role is authenticated (users, third-party service providers, local libraries), can embed software developed by their own., this will allow an open platform for better sharing, and cloud service center will be based on the quality and the condition of using to filter out the reliable and popular software, which will become the basis for the collection of services software layer.

2.3 SAS (Software Air Serves)

Software Air Serves are based on PAAS Layer, which contains all of the applications needed by library users. These applications come from two major sources. First is the application open

platform. Cloud software service provider rent the right of software use, and users are able to rent software as required, not the way of payment. Secondly, the application software developed by cloud service center. The software engineer of cloud service center will independently develop a part of core application software based on the system of PAAS layer, which including the series software of personal digital library service, online office system software and database service software, etc. Cloud service center preserve ownership and use right on the software developed independently and only participate in profit-sharing through rental software, but it does not have the ownership for the third-party developed software, which take responsibility for software management and maintenance. The application software of service layer is not exclusive, but has a super sharing [4].Those software are arranged in a "cloud" side, and different users can use these software service online. The reason is that the virtual resource pool of IAAS layer have a good flexibility, it can support the computing of application software and changes of storage capabilities to ensure the service. When the needs of users surge on the same software, the underlying elasticity can provide reliable communication, computing capability and storage space. While the user log off or reduce the use of resources, the occupied resource of this software will decreases with it, and the space computing capability will be used to support other software systems running. Users will be able to use the high-performance software services through the cloud and pay the appropriate fee based on time, without concern for software maintenance and management. As for cloud service center and the third-party software providers, the paid sharing of any piece of software can bring service value and profit sharing. Since the operation of open platform of the PAAS layer, SAS layer will inherit its openness. Cloud computing concept is supplied on demand, but the change needs of users is infinite. So the professional third-party software service providers offer thousands of software services and ensure the software updates and maintenance, but this is not able to fully keep up with the changing needs of users.Web2.0 era let each network user of us become a "weaving man", it is opening of Web2.0. Similarly, the opening of SAS layer is that the user can also add independent and opening software [5].

Conclusions

In addition, cloud computing provides a convenient and coordinating information sharing for information users. Wherever the users are, as long as they access to the "cloud" side, they can not only take advantage of a unified virtual platform, provided by cloud computing, and continue their work, but can also share their data on multiple devices.

Data Integration in B2B E-Commerce

Yan Zhang

School of economics and management ,Xinxiang university, Henan, China

zshazhu@163.com

Keywords: E-commerce;B2B market; communicate

Abstract: the dramatically increased flexibility afforded by the Internet in business-to-business transactions also presents steep challenges in merging information coming from so many sources. B2B marketplaces, which function as an intermediate communications layer, reduce the number of mappings needed .

1 Introduction

A successful marketplace must integrate various hardware and software platforms and provide a common protocol for information exchange. However, the real problem is the exchanged content's heterogeneity and openness. This heterogeneity arises in at least three levels: the content, product catalog structure, and document structure[1].

The content of the exchanged information must be modeled. Historically, many different ways to categorize and describe products have evolved. Often, vendors have their own private way to describe their products. Structuring and standardizing the product descriptions is a significant task in B2B e-commerce, ensuring that the different actors can communicate with each other so that their customers can find the products they want. Here, content management solution providers can offer added value by helping their vendors build and instantiate an ontology for certain product domains.

E-commerce is about electronically exchanging business information—of which product descriptions are just one element. The product descriptions are an electronic catalog's building blocks, together with information about the vendor, the manufacturer, the lead time required, and numerous other business-related considerations. Furthermore, a catalog provider should include quality control information, such as catalog version, date, and identification number. The total composition of these building blocks is called the *catalog structure*. Where there are two electronic catalogs involved—for example, when two vendors in one marketplace have different catalog providers, or when two different marketplaces want to communicate—the structure of these catalogs must be aligned as well.

Going one step further into the content-management process, we come upon the catalog's actual use. In a marketplace, a buyer will want to send a purchase order after picking up the necessary information from the catalog. The vendor must reply with a confirmation, which starts the buying process. For the buyer and the vendor to read and process each other's business documents again requires a common language. Marketplace software developers such as Commerce One, which developed its structures based on the xCBL language, provide a large collection of document structures that reflect different aspects of a trading process. Aligning these document structures with other document definitions such as those from Ariba (cXML) is far from a trivial task[2].

Consequently, three types of mismatches can arise. The first type, in content, mainly concerns the real-world semantics of the exchanged information: people describe the same products in different ways. The second and third types, in product catalogs and business documents, more generally concern the exchanged information's syntactical structure.

The overall information integration process must tackle a number of serious problems. In particular, product descriptions must be structured; classified; (re)classified and (re)described in various dimensions because no standard product classification exists; and personalized to let customers find the products they seek. Figure 1 provides a snapshot of the overall process.

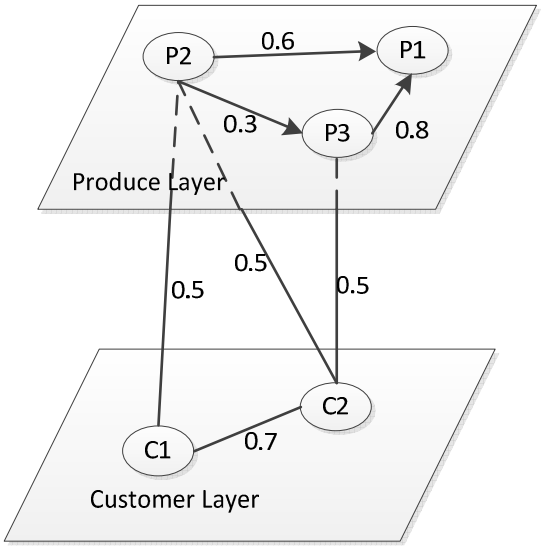

Fig1 Overall process.

2 Information integration in B2B e-commerce

With the progress of human science and technology, the renewal speed of knowledge is increasing, if the person just rely on the traditional teaching mode and teaching method to learn the knowledge of books, that when the learning process is ended，knowledge what learners are learning may already outdate, it is undoubtedly a great irony, also unnecessary waste of education resources in short supply conditions，knowledge is processed by using the digital information technology, and transfer and share in various learning equipment[3]. Learners can use the internet to visit education resources of universities, libraries, education institutions, without restriction by the lectures and books. Thus education of knowledge application value is in the maximum. The application of digital information technology, not only improve the education resource sharing rate and utilization rate, but also cause the transfer of teaching ideas. It is well-known that "the science and technology are the first productivity", Productivity means that the social demand for high-quality talents are also ascending simultaneously, the simple of talent training mode in the past is out of date in fierce competitive society already, only full of knowledge, skilled, strong learning ability, creative thinking people can be available and become the most outstanding person in the society. In recent years, educational experts point out that the new way of education in which the traditional way of learning activities the teacher is the center transfer to the learners as the center, and the digital information education resources provide enough solid technical support to the new mode of education practice.

Suppliers have product catalogs that describe their products to potential clients. They want to make this information available online through a B2B marketplace. Because so many product catalogs already exist electronically, you might think this would be a simple task. However, these product catalogs are designed for the human reader. Thus, extracting the actual product information, classifying it, normalizing it, and storing it in a structured format is primarily a series of manual tasks. Content management solution providers often have several hundred employees working in content factories to manually perform this information processing, often starting with only printed catalogs.

3 The characteristics of electronic commerce

（1）Trading virtualization Through represented by the internet computer internet network in the trade, trade both sides from trade negotiations to pay was done through the Internet, such as the transaction virtualization.

（2）Low transaction cost No intermediary participation, reduce the intermediate links to deal, paperless trade reduces file handling charges, the seller can undertake product propaganda through the Internet, reduce the advertising expenses. No store, save the rent.

（3）High efficiency Companies use the internet to transfer information, improve the information transmission rate. Computers can store large amounts of information, query generation consumers,

can transmit information quantity and accuracy, far more than other media, and can meet the market demand, update the product or adjust the price, so can effectively understand and meet the needs of customers in a timely manner.

（4）Hyalinization Buyers and sellers trade negotiation, signing and pay to the delivery notice of payment, the entire transaction process in a network to ensure the all kinds of information query and check it.

（5）Worldwide The characteristics of the Internet is under the condition of the network popularization, the information can be radiation to the world, and Shared by people, under the condition of the electronic commerce globalization, globalization shopping.

（6）Harmony In the e-commerce environment, it requires more various merchants, payment, logistics and distribution center, communications department, technical services, and other departments ability of cooperation.

Taobao, founded in 2003 on May 10th, founded by alibaba group investment at present, taobao is Asia's largest network retail business circle, the goal is committed to create a global network retail business circle. By combining community, river's lake, gang to increase the viscosity online population, and using the latest online mode, make online shopping the crowd very happy. The emergence of taobao for the entire network shopping market to create a transparent, the good faith, fair and open trading platform, whitch will affect people's shopping habits. Promote offline market transparent, integrity, as well as the production and circulation. Thus derived a "open and transparent, sharing, and responsibility" of the new commercial civilization[4]

Profit model

（1）Direct sales Make purchase price and sale price difference between the online sales, more than 30000 kinds of product varieties, product 10% cheaper than offline stores - 20%.Inventory turnover rate for 12 days, the spot with suppliers now, had a 7% lower rate than gome, sunning, gross margins around 5%, the industry chain of suppliers and end customers to provide more value. Implementation of jingdong "low stress scale" of the business model.

（2）Virtual store rents Store rent, products of landing fees, transaction fees.

（3）Precipitation money income Using the received customer payment for goods and pay the supplier time lag of money precipitation reinvested in order to gain profit. Jingdong mall on the third-party payment platform have Tenpay, Bill and Alipay.

（4）Advertising expense At present, the network advertisement gradually accepted by people, for some large media websites, online advertising has become one of the important source of business income.

4 Classified product descriptions

At this stage of the content-management process, we can assume that our product information is structured in a tabular way. Each supplier might use different structures and vocabularies to describe its products, but that might not cause a problem for a one-toone relationship where the buyer could well get used to the supplier’s private terminology. B2B marketplaces that enable *n–m* commerce cannot rely on such an assumption. They must classify all products according to a standard classification schema that helps buyers and suppliers communicate their product information. The Universal Standard Products and Services Classification is a widely used classification schema in the US [5].

UNSPSC was created when the United Nations Development Program and Dun & Bradstreet merged their separate commodity classification codes into a single open system. Currently maintained by the Electronic Commerce Code Management Association (http:// eccma.org), a not-for-profit membership organization, the UNSPSC is a hierarchical classification with four levels: segment, family, class, and commodity. Each level contains a two-character numerical value and a textual description.

Again, classifying the products according to a classification schema like UNSPSC is a difficult and largely manual task. It requires domain expertise and knowledge about the product domain,

which makes the process costly. High quality is important for ensuring maintainability and visibility of product information [6].

Election System Based on Prior Knowledge

Wu Guodong[a], Liu Zhengyi[b]

College of Computer Science and Technology, Anhui University, Hefei, 230601, China

[a]email:wookwoktung@gmail.com, [b]email: liuzywen@ahu.edu.cn

Keywords: Election system; prior knowledge; Ballot input direction; Efficiency; Multiple election options

Abstract. In order to optimize the election system, we present a vote counting system based on prior knowledge, which makes the ballot style more flexible. The system processes votes by using prior knowledge presetted after obtaining images from the scanner. And it can effectively determine ballots' side to solve the problem of direction uncertainty. The speed of processing each ballot is improved so the problem of limited efficiency can be solved. In addition, the system identifies the position of each option on the ballot to solve the multiple options problems. Experimental results show that the method of the system development is reasonable, effective, and it has high practical value.

Introduction

With the rapid social development, electoral system becomes the main democratic system of our country. People select suitable candidates for specific positions in accordance with certain procedures. Currently, several methods have been widely used. The method of processing ballots manually is very primitive and time consuming. Using Optical Mark Reader (OMR) to process ballots [1-3] needs special ballots. Electronic voting [4-7] is easy to operate but can hardly be accepted by voters because there are no ticket stubs. The method based on layout understanding and Optical Character Recognition (OCR) [8-12] is proposed to compensate for disadvantages of previous methods. This method uses the technology of OCR to recognize the election results after acquiring scanning images of ballots. We compare these four kinds of election methods and the results are shown in Table 1. Apparently, we can see the election system based on layout understanding has superior advantages. However, it still has some disadvantages. The speed of processing ballots is limited because we need to correct some skewed ballots. Meanwhile, it cannot effectively deal with the multiple options problems. In order to improve the election efficiency, Chan et al. [10] proposed a recognition algorithm based on the run-length of table line, which omits the step of tilt correction. The idea of the algorithm is to put all the election information in a table at first, then find out all of the horizontal and vertical lines in the scanned images, finally define each cell based on the intersection. In order to solve the multiple options problem, Zhang et al. [12] proposed a recognition algorithm based on hierarchical division. The main idea is to put the entire election in a table, each subtable represents an electoral item, then search for cells step by step according to the four sides of border. In this paper, we propose a prior knowledge based election system on the foundation of the two approaches. We first scan the ballots, then use the preset information to identify the votes and the voters' intention and eventually count the election results.

Table 1. Comparisons of several election methods

Election Method	Manual	OMR	Electronic Voting	OCR
Accuracy Rate	General	High	High	Relatively high
Speed	Slow	Relatively Fast	Fast	Relatively Fast
Flexibility	High	Poor	High	High
Paper Ballot	Yes	Yes	No	Yes
Security	General	High	Poor	High
Cost	Low	Relatively High	High	Relatively Low
Acceptance	High	General	Low	High

Election Settings

Ballots setup. When more than one position needs to be elected in an election, each position will form an election option. But the election may contains more than one election option and too many candidates that can't be displayed on one ballot, normally, we solve this problem by putting one election option in one ballot and use different colored ballots to represent different election options. But then voters are required to fill in multiple ballots, so sometimes, some ballots are omitted to be filled. In this paper, we design an election system based on prior knowledge, which can process both sides of the ballot to solve such problem, at the same time, the number of ballots is reduced.

The ballots we use in the system contain several election options which can be arranged in both sides. Every election option is composed of several parts: name of election, the electoral requirements, names of candidates and other candidates. We can set the bar code to identify different ballots, election options, and the side of the ballot. Fig 1 shows a simple election ballot. Voters need to fill in the symbol like "√,O,×,\,—, / " under the columns of candidates to express their intention. The system uses the technology of OCR, which is a good method to identify various ballots and symbols. One simplest way is to fill "√" to express yes, use "×" to express no, and use "—" to express abstention. At present, the technology of OMR is widely used in electoral system, but the ballots have two columns that represent support and abstention respectively. As shown in Fig 1. So the system we proposed also needs to process such kind of ballots.

List of Candidates

(elect one from the following two)

Candidate	Opposition	Abstention
Tom		
Jim		

Choose Another

Figure 1. One simple election option

Prior knowledge of the election. The prior knowledge required in the system includes the following three categories:

(1) Ballots layout information

The information includes: (a) whether the ballot has two sides. (b) the maximum number of candidates, the maximum number of other candidates, the number of bar code and the location of its horizontal lines. (c) the way to distinguish the ballot's directions.

(2) Election options information

The information of one selection option include: the storage location of election options information, the name of the election options, and the side of the ballot. As well as the information about ballot's layout, the meaning of each symbol, the list of candidates, the information about voters.

(3) Election information

The information of one election may contain multiple election options which include the name of each election option, the storage location of election options information, the serial number of the ballot, election rules, the devices used.

The method of ballots processing

To be able to recognize the information of the ballots, we process images according to the flow shown in Fig 2 after getting the scanned image of ballots.

(1) Find all horizontal lines

Traverse both side of the image we scanned, to capture all the horizontal lines of an image. However, images may be skewed and the lines may be intermittent. We solve this problem as follows: Firstly, find out black pixels around a black pixel we found in advance. Secondly, use the

"two points determine a line" axiom to determine the direction of the line. Then along this direction looking for other black pixels nearby. Finally, referring to the proximity relation of their ordinate values, we link two pixels where they have nearest abscissa values. If we find that the length of a line is different with the lines we preset in the layout, then we will ignore it. After finding out all horizontal lines, examine if the number is consistent with the number of lines presetted. If so, continue the following steps, otherwise this ballot is invalid.

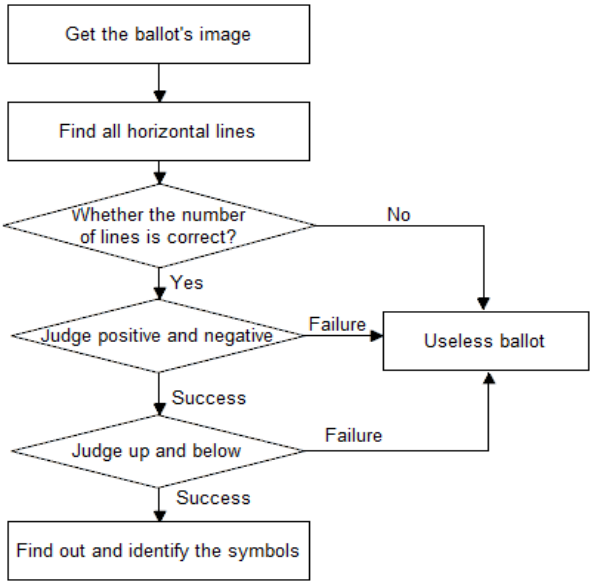

Figure 2.The flow of ballot's processing

(2) Judge the side of ballots

If the election information is only displayed on one side of the ballot, then we can judge the positive side of the ballot by examining whether there are lines or not. If both sides of the ballot have election information, then we use the presetted prior information to identify the ballot's positive and negative side in three ways: (a) horizontal lines: If the number of lines is different in two sides, then the number can be used to judge the side of the ballot. (b) the margin of the ballot: If the sum of top margin and bottom margin is different in two sides, then this feature can be used to represent different sides. (c) Bar code[13]: we can judge the side of the ballot by checking whether there is a bar code. If we successfully judge the side of the ballot in this step, then continue the following steps, otherwise the ballot is invalid.

(3) Determine whether the ballot is upside-down

We use three kinds of methods to judge whether the ballot is upside-down: (a) the margin of the ballot: if the top margin is different with the bottom margin, we can determine the direction by comparing the margin. (b) special regions: if there are two centrosymmetric regions, they have different pattern, for example, one region has black lines or word marks and another region is empty, then this feature can be used to determine the direction. (c)bar code: If two regions are centrosymmetric with each other, and one of them have a bar code, then the feature can also be used. If we find a ballot is upside down, we rotate the image 180 degrees.

(4) Find out and identify the symbols

According to the correspondence between lines in the ballot image we scanned and lines presetted, along with the information about the location of fill-in columns, we predict the location of rectangle boxes in the ballot's image. Though the image may be skewed and the location of rectangle boxes we predicted may not be right, the center of the rectangle box is in the practical fill-in column. So we can use this center point to find out the rectangle box's four vertexes, then use these four points to get the rectangle's real location. At last, according to the symbols in the fill-in columns that we scanned, we count voters' intention about the election. The judge criteria towards symbols "√,O,×,\,—,/" are shown as follows[14]: (a)"√": scan the image pixels from top to down, in the upper part, each row is filled by a single point, in the lower part, each row is filled by two

non-adjacent points. (b) “O”: each row has two non-adjacent points. The distance between the two non-adjacent points becomes bigger at first and becomes shorter later. (c)“×”: each row has two non-adjacent points, and the distance between the two points becomes shorter at first and becomes bigger at later. (d)“\ ,—, /”: each row has a single point.

(5)Statistics

When we get the symbols written by voters in previous steps, then we can count the final results by calculate symbols’ location and meanings.

Experiments

The election system based on prior knowledge is developed by using C# language in VS2010 environment. The operating environment is Intel (R) Celeron (R) CPU E3400@2.60GHz, 2GB of memory. We evaluate the system by testing ballots in different direction. In each direction we detect 100 ballots. Detection results are demonstrated in Table 2.

Table 2. Experimental results

Direction	Upward Positive	Downward Positive	Upward negative	Downward negative
Average processing time	265.6 Ms	312.5 Ms	353.1 Ms	412.1 Ms

Experimental results show that the average processing time is shortest when the ballot is right side up, if we change the ballot from up to down and front to back, the average processing time is longest. That’s because the system needs time to correct the ballot’s direction.

Conclusions

In this paper, we proposed a method to solve the problem of multiple election options and it had a high efficiency. Once voters fill the ballots with standardized symbols, the system can process the ballots faster and better. But in the case of processing non-standard symbol, the result was not ideal. Therefore, we need to focus on how to improve the technology of character recognition in future studies.

Keywords: Media resource, cloud storage, massive data

Abstract. Cloud storage has become increasingly widespread application and deep into various fields of radio and television industry. In this paper, we researched the approach to store media resources of video on demand based on the network and of televisions, in the context of tri-play network convergence. We presented media resource management in conjunction with cloud storage to manage massive data, and build a resource sharing platform types of content without limits, instance participation. Thus information providers and information recipients become an integral relying on the Internet.

Introduction

Cloud storage is based on the development of cloud computing, which results from Distributed Computing, Parallel Computing and Grid Computing. The massive data in the cloud is divided into many small parts to be computed in large system consisting of multiple servers. And the system returns the calculated data to the users. Network service providers can deal with tens of millions of information in a few seconds with cloud computing. Cloud storage provides data storage and service access by a large number of various types of storage devices with the application of cluster application, network technology and distributed file system.

To put it simply, users connected to the cloud through the Internet and transmit storage resources to the cloud. The system provide guarantee to protect the data safe at the same time to save the storage space.

Cloud Storage Architecture

Users enjoy a variety of services such as upload or download files, read files, classified files, backups and so on with cloud storage system.

The system model is shown in Fig.1.

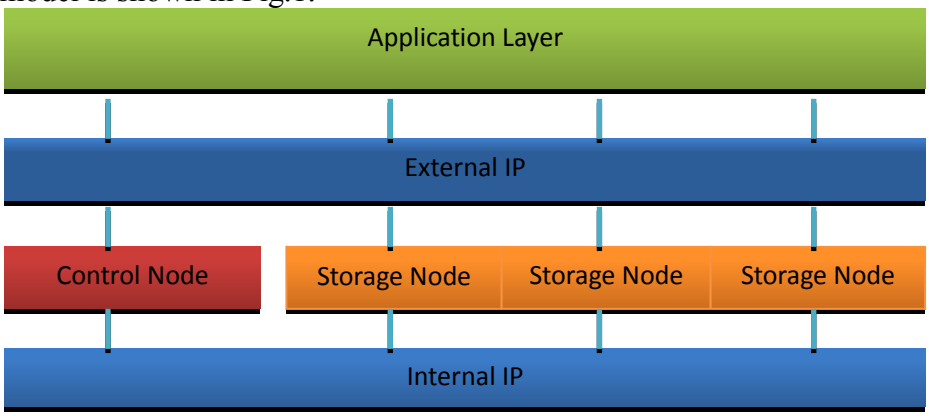

Fig.1. Cloud storage architecture

The storage nodes are marked as orange, they are used to file all documents which uploaded by users. And in red is called Control Node and used to monitor the orange parts' storage capacity, at the same time control loads balancing. The red part and orange parts constitute a cloud storage. Control node and storage nodes are all servers, and more hard disk in a storage node server than control node server. This is determined by the characteristics of a storage nodes server. Each storage node and control node needs at least two network cards, one piece is used for communicating with storage node or control node and transmitting data; the other piece is used for interacting with external application terminal data.

Application terminal needs a PC is used for the storage nodes management in cloud storage. Cloud storage is a file management system for the application side, supporting many network protocols such as NFS, HTTP, FTP, WebDav and so on. This characteristic makes the old system is easy to combine with the new system.

An Overview of Media Assets Management

Media asset contains two parts: media content includes digital media audio and video files and other information beyond media content which are called as metadata. The two parts are respectively stored in different database. The metadata does not have a separate existence value, it is the description of the media file information, including basic information file name, category, edit information etc. Storage management and metadata management of media content is combined with a set of digital media assets for the user, data storage, management, retrieval catalog browsing in a complete solution.

The Media Asset Management System Based On Cloud Storage

In this paper, cloud storage and existing media resources management system are combined, established special cloud storage for audio and video programs. Some equipment and cloud system are connected, these devices are storage devices, the streaming media server, communication server. These devices are arranged in cloud, integrated upload, cataloging, storage, query audit of media resources. A simple architecture is shown in figure 2.

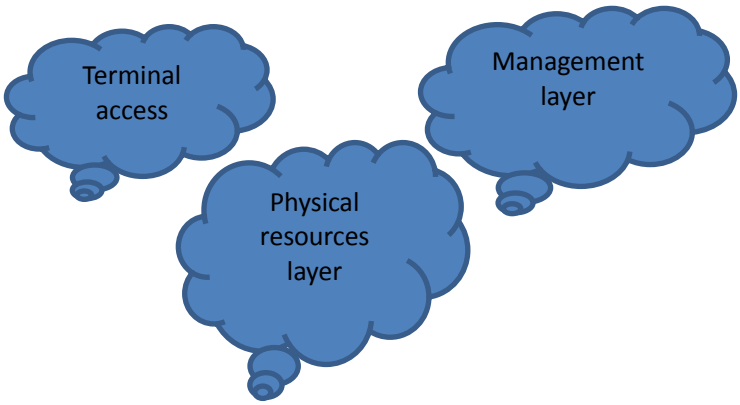

Fig .2 Architecture of media assert management

Storage devices, transport servers, transcoding servers, import and export workstations and other physical equipment are stored in the material resources layer. Terminal access layer upload, cataloging, searching, audit and management operating by using several of internet terminals. Management layer is used to management the operation of configuration, storage and content processing. Processing these operations in the clouds, reduce the pressure of local server. Resources are storage in the type of tape or disk is converted to digital resources.

DESIGN OF AUDIO AND VIDEO ASSET MANAGEMENT SYSTEM BASED ON CLOUD STORAGE

The platform adopts the streaming media server as a storage of audio and video media asset hardware platform, This system includes injection module, content editing module, content audit module, content packaging and classification module and the content query module, to complete the injection and edit the content information, playback and review the video, packaging and content of the classification, the content query function. The structural diagram of the structure has shown in Fig3.

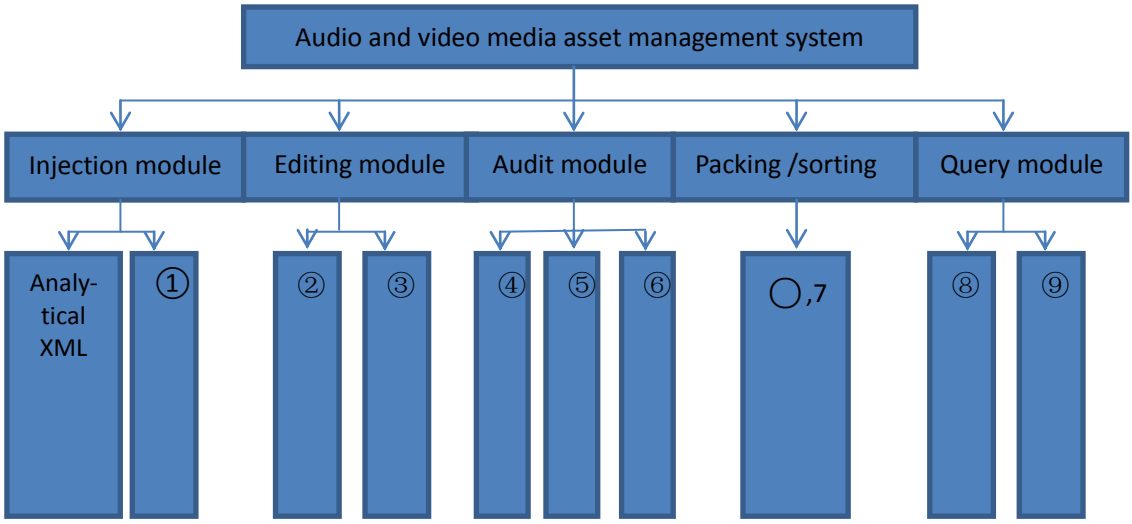

Fig .3 Audio and video media asset management system structure diagram

No.1 representatives content injection module which mainly supported formats for on-demand content metadata information like MP3, MOV, flv, RMVB, mpg.

No.2 representatives modify the content information. No.3 representatives delete the content information. Content editing module can edit information which has been injected into the content .

No.4 representatives video playback. No.5 representatives add audit reasons. No.6 representatives video injection. The content of audit module mainly realizes the video information successfully injected into the content playback and review, by calling the streaming media server interface, the content which has passed audit injected into the streaming media server.

No.7 representatives add the content packaging and classification. Content packaging and classification module realize content business packing and sorting function.

No.8 representatives the query input. No.9 representatives contents of fuzzy retrieval. The content query module can provide function which according to the query condition, return the content list in accordance with the terms of the query.

The system can be deployed separately, independent processing complete content injection, editing, audit, packaging and classification and query functions. System information processing process is shown in figure 4.

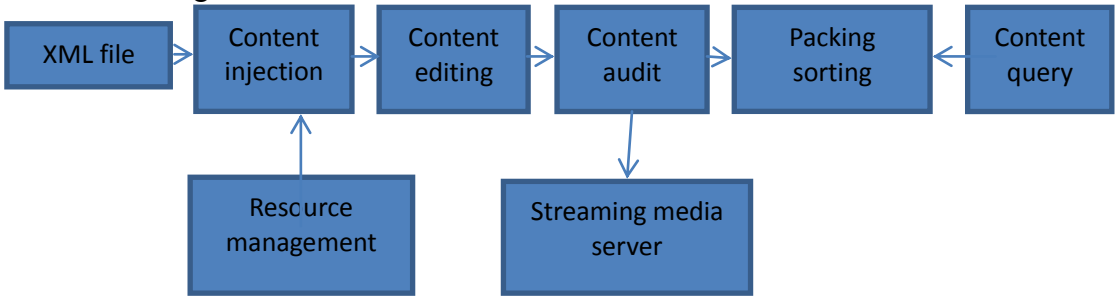

Fig. 4 Information processing system

The code shown in the following which used to inject the content information of the source data into the database management after treatment:

```
<?php foreach($result as $key => $item): ?>
<tr><td align="center"><img src="<?php echo $config['root']; ?>admin/mms/poster/<?php echo $item->logo; ?>" width="60" height="60"/></td><td align="center"><?php echo $item->guid; ?></td>
<td align="center"><?php echo $item->name; ?></td><td align="center"><?php echo $item->streamtype; ?></td> <td align="center"><?php echo $item->resolution; ?></td>
<td align="center"><?php echo $item->type; ?></td> <td align="center"><?php echo $item->live_url; ?></td> <td align="center"><?php if($item->insert_complete == '0')
```

SUMMARY

Cloud technology has the characteristics of flexible, efficient, real-time etc. Various industries put these characteristics to good use not only promote the rapid development of the cloud but also contribute a lot to its development. The combinations of radio and television system and cloud technology improve the efficiency of resources storage and offer convenient services for audio and video resources play and transmission. These combinations enrich the form of the radio and television industry, improves efficiency, reduce cost, provide greater development space for the radio and television industry.

Keywords: Interest community; P2P; Chord; piecewise hash

Abstract. Through utilizing node interest community in P2P network, put forward a new method on how to combine node interest community and traditional Chord algorithm. By using piecewise hash, making nodes in the same interest community adjacent to each other in the Chord algorithm, forming a virtual double Chord ring structure. Simulation tests show that this method is superior to the original Chord algorithm at path length and routing latency, improving the scalability of system.

Introduction

With the rapid popularization of P2P network, resource search performance of P2P network has attract the user's attention. Studies has shown that in P2P networks ,there has been the existence of interest community between nodes as in the social network .Because the network community can bring a good user experience , such as Shared resources.When the nodes want to look up resources, first of all ,it will look up the resource in the community that it owns to, due to the nodes with similar interests are more likely to find the resources each other. if the query can be met in the community , then it can narrow the search scope, shorten the query path length,the community has become Repeated communication object.

In unstructured P2P networks, existing methods are mainly concentrated in the use of the formation standards of the community for the choice of routing nodes [1-4], in unstructured P2P networks ,it is relatively simple to use the ideas of community , because the standard of nodes forwarding the query message is based on community relations between nodes thus reducing the number of invalid forward, to a certain extent, improve the efficiency of resource search.In structured P2P (refer to as DHT (Distributed hash table) network) network, each node has a unique identifier, every resource also has a unique resource identifier.According to some kind of mapping rules, the resource identifier is mapped to a node identifier.Resources are mapped to the corresponding node, thus formed a lot of (Key, Value) pairs, all of the (Key, Value) pairs constitute a large hash table, each node is responsible for part of the hash table.If we want to apply the idea of community to the unstructured P2P network to improve the efficiency of resource search ,that will be a challenge.In [5] ,considering the interest of nodes, when forwarding query message ,first select nodes with similar interest with itself for forwarding.The basic idea is that if a node is able to meet query request of another node , that means the two nodes are likely to have the same interest , the next query will forward to the nodes in the first place.However, the measurement criteria of node interest is not accurate.Therefore,in[6],the author put forward a classification method of node interest ,and in turn,the nodes can be classified. This method can measure the interest of nodes more accurately,but it need to traverse all the text in nodes,thus limit the size of the system.In [5],the query request is forward to only one node,in order to using community relations between nodes,the method of establishing a interest community is put forward[7] .

All these above methods are based on to save the interest nodes list for each node,With the expanding of network size,the size of interest nodes list will become larger ,the system has poor scalability.This article is based on the former method ,proposing a new method on how to combining node interest community and DHT(for example: Chord[8])network.

1 .The discovery method of network interest community

Community structure is an important feature of peer-to-peer networks. The current community discovery methods mainly include the method based on edge betweenness [9], the method based on spectral clustering and the method based on random walk [10,11].

In this paper, the creation of the interest community algorithm derives from the past research of network community, mapping the interest community to the network maximum flow problems. Node interest community reflects the range of node interest, including the nodes that have similar interests. In order to build node interest community,we should make sure which nodes made of the community. One of the methods is based on the historical data, namely, whether node X can satisfy the request from the node Y in the past period of time. The method of this article is utilizing the current sharing content of two nodes to determine the similarity between nodes .

Node interest communities can be seen as a undirected graph, with the vertex as node.when two nodes share a common interest such as the same document,then establish an arc between the two vertex.Each arc can set an weight according to the different measurement criteria , this article uses the number of same keywords between two nodes as the weight of the arc.The node that create community called seed node , at first place, seed node try to find the nodes that have shared the same document with it in the network.The specific method can be seen as follows :Seed nodes randomly selects a subset of keywords and send the request to some nodes in the network, check to see if these nodes stores these documents; the nodes that processing the request is selected from node set known by the node which send the request . The nodes that share at least one keyword with the seed node are added to the graph , the depth of this nodes is 1, that is, they attached directly to the seed node.when it comes to the second step, for the nodes (named p)that added to the graph in the first step repeat the action of seed nodes ,some new nodes (can be named as q) will be added to the graph with the depth of 2.Then a arc can be produced between p and q with the shared number of keywords as the weight .Third step,add a point as the collect point and make connections with all the nodes in the graph.Deciding the friend nodes of seed node by determining maximum flow between the seed node and collect point and then build the interest community of seed node.The select standard of seed nodes is in the light of the number of the documents stored in the nodes.When a node belong to multiple interest community ,then it joins the community with the biggest similarity .

2.Resource query mechanism based on the interest community of nodes

Chord uses consistent hash function to compute nodes and keyword identifiers.By hashing the IP address and the keywords of document can obtain the identifier of node and keywords. Then the identifier of keywords is mapped to the identifier of nodes.In Chord , all nodes are organized into a single ring with the size of 2^m.The keyword identifiers is stored in its successive nodes.In traditional Chord ring, the query request is based on the hash value of query keywords.The key problem of query is looking up the successive nodes of keyword.

When taking the node interest community into consideration ,by adopting the idea of piecewise hash,allocate a community identifier for each interest community .In Chord,nodes is represented by the correspond node identifier with m bits,in order to making the nodes in the same interest community can be adjacent in the logical space,we adopt piecewise hash and divide the m into two parts:m1 and m2,with m=m1+m2. Assuming X and Y is correspond to the community identifier and IP address of node,so node identifier can be divided into two parts ,Xid andYid,expressed as N(Xid,Yid).N.Xid=Hash（X）mod 2^{m1} and N.Yid=Hash（Y）mod 2^{m2} ,N=Xid* 2^{m2} +Yid.Xid is made of the former m1 bits of node identifier and determined by the community identifier,Yid is made of the m2 bits of node identifier determined by the IP address of node. Because all nodes in the same community have the same community identifier,bringing about that nodes in a community is adjacent in the logical space ,resulting in the virtual double layer structure(as shown in figure 1).Selecting a node with good processing ability as the leader node to be responsible for the query request between communities.When the search request of the nodes have not been met in the community that it own to ,then the leader node will forward the request to the other communities in

accordance with the traditional resources localization algorithm of Chord.This method have superiority not only in the lookup time delay but also in the scalability.

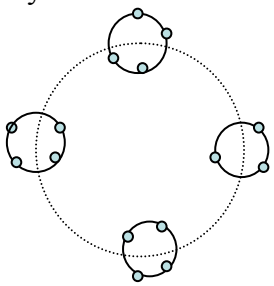

Figure 1 Virtual double layer structure

3. Performance Evaluation

We have conducted simulation experiments to evaluate routing performance of our model .In this paper, the testing standard is the average search path length and the average routing latency.we use Test1 as the test result of our model and Test2 as the test result of the traditional Chord search algorithm .

Experimental parameters is mainly include the number of nodes , the number of documents and the number of resource requests with the proportion 1:1:10.In our simulation ,we vary the number of system nodes from 200 to 3200.

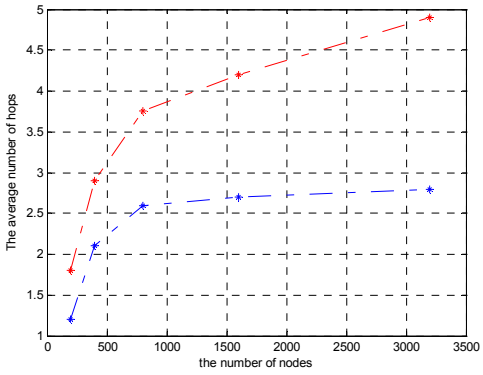

Figure 2

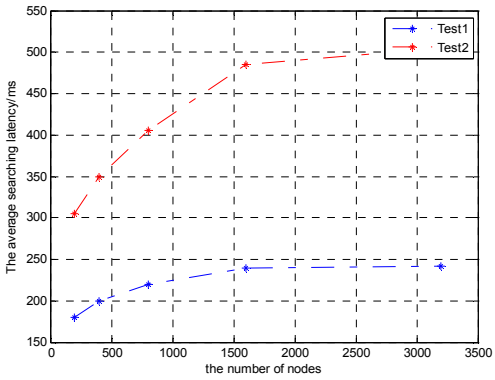

Figure 3

(1)The average search path length

Path length refers to the logical network hops the node that issues a query request has passed until find the resource. Figures 2 shows the comparison results measured by metric of “Search path length .Assuming that each community contains m nodes and there are N nodes in the network .The complexity of looking up is 0（log N）in the traditional Chord. When it comes to the model in this article ,then the complexity of looking up will only be 0（log m）if the query request can be met in the local community.

(2)the average routing latency

When users want to find resource ,it will first look up in the community that it own to and also the success rate is relatively high .Therefore ,the average routing latency becomes shorter on account of the shorter in the Search path length ,as is shown in the figure 3.

4. Summary

In this paper ,we propose a new model for the resource query in the structured P2P network and make explanation in detail for the resource search mechanism.By analysising the simulation result we conclude that the model that we proposed is superior compared to the traditional Chord algorithm.However ,this paper does not take the forward among interest communities into consideration .The interest correlation among communities also affect the efficiency of resource

search to a certain extent .In the next step ,we will study the message forwarding mechanism among communities.

[a]348237548@sina.com

Keywords: Data Mining, Accounting Decision Support System, Data Warehouse

Abstract. With the intensification of market competition and the demand of information society development, extracted from large amounts of data (retrieval and query, etc.) used for decision making and analysis of information becomes more and more important. Through the accounting data warehouse design, data extraction, data maintenance, accounting decision-making needs design, mining algorithm is designed, and the mining operation, the expression and interpretation, etc, can discover useful from vast amounts of financial data, important information, etc. Provide scientific decision-making for the enterprise development, leading technical support.

Introduction

DSS (Decision Support System), Decision Support System, is in the process of semi-structured and unstructured decision-making activities, through the man-machine dialogue, provide information to Decision makers, to help Decision makers find and analyze problems, to explore the decision-making plan, evaluation, prediction and options, in order to improve the decision-making efficiency of a by means of computer information systems. The accounting Decision Support System (ADSS) is the application of Decision Support System in the field of accounting, is on the basis of accounting management information System.

At present, the market of all kinds of financial management software, and decision support system to a large extent is the manifestation of quantitative technical decisions. Mathematical model is set up is their common characteristics significantly. However, not all influence business decisions in the practical work of information can be completely quantified. Especially in the complicated environment enterprise facing many decision problems, tend to be goal vague and multiple targets conflict each other, scheme comparison and selection of no fixed rules or procedures, required information is not complete or vague, this kind of decision problem, based on the relational database of ADSS couldn't solve. Based on data warehouse and data mining technology to construct the accounting decision support system solutions can effectively solve the unstructured accounting decision problem.

1 Data warehouse and Data Mining

With the intensification of market competition and the demand of information society development, extracted from large amounts of data (retrieval and query, etc.) used for decision making and analysis of information becomes more and more important. This demand requires both online services, also involves a large amount of data for decision making, and the traditional database system has been unable to meet this need. It embodies in three aspects: history data volume is very big; Auxiliary decision-making information data involves many departments, and different system data integration; Due to lack of the ability to access data on a large amount of data access performance decreases obviously.

With the maturity of C/S technology and the development of the parallel database, the development trend of information processing technology to extract Data from a large number of transactional database, and clean up into a new storage format, it is the decision goal the Data aggregation in a special format. With the development of the process and improvement of the support decision making, special Data storage that is referred to as a Data Warehouse (Data Warehouse).

Data warehouse technology was applied to build the accounting decision support system, can realize centralized storage and management of accounting data, which can reduce the time of I/O and computing time, reduces the data redundancy, and solved the DSS system is inconsistent with the data in the database.

The key technology of data warehouse including data extraction, cleaning, conversion, load, and maintenance. The basic framework of data warehouse is shown in figure 1.

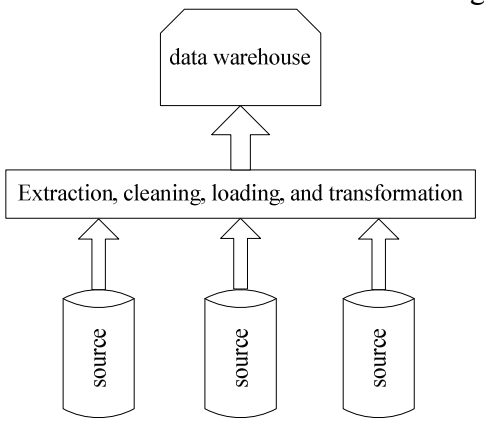

Fig1 Data warehouse framework

Accounting information system running after years of accumulated mass, in various forms of storage data. But when faced with more and more rapid expansion of the database, but people don't begin to understand the information contained in the data, more difficult to gain valuable knowledge, the original decision support system (DSS) can not meet needs. Concept of data mining is to make people have the ability to overcome the difficulties, to discover the contained in the data information and knowledge. Data mining is the international one of forefront research direction in the field of database and information decision, caused the wide attention of academia and industry.

Using the data mining technology to the accounting decision support system, will benefit from a large amount of data found potential, valuable, and unknown relationships, patterns and trends, and represented in the form of easy to be understood. Through data mining in ADDS to found the complex relation between data and the effect of the contact of decisions.

Data warehouse is a to better support the enterprise or the organization's decision analysis process of data collection, data warehouse technology to complete the enterprise internal work, all kinds of business data integration for enterprises laid a solid foundation for subsequent business application; Data mining from huge amounts of data, extract implicit in it, people don't know in advance, but potentially useful information and knowledge. The process of data mining analysis on the data warehouse, can find many cannot find information manually, can want to come to the conclusion that. So can say: data mining is a data warehouse on value-added technology.

The data mining based on data warehouse, on the one hand, can improve the ability of the decision support of data warehouse system; On the other hand, due to the completed data cleaning, data warehouse ETL (extract, transform, load), data mining is facing through preliminary processing of data, more conducive to data mining function.

2 Data warehouse and data mining based accounting decision support system

In order to effectively accounting decision, solve the traditional ADSS can't solve the problem of unstructured decision making, based on the data warehouse and data mining technology to build the accounting decision support system is feasible, the basic framework is shown in figure 3. The system, remote data mainly comes from internal and external accounting and management system and its related systems; Data model USES the set up time, business dimensions, such as user geographical and multidimensional data model; The function of the system structure can be used C/S architecture, by the client, application server and data warehouse server.

Accounting should be clear at the beginning of building the data warehouse theme, according to the analysis of the theme target integrated all the relevant data and information, integration, the

greater the amount of data, the more comprehensive, the more accurate decision analysis conclusion more objective. The construction of data warehouse is a spiral development process, with the passage of time, can adapt to different needs. The theme of the major accounting data warehouse contains are: the theme of the economic forecasting, pricing decisions, investment decisions, corporate sustainable development forecast, product marginal profit forecasts, etc.

Build a data warehouse of accounting requires the following process:

1, accounting data warehouse design. According to the accounting decision subject design data warehouse structure, general star model and snowflake model was adopted to design the data model (model), in the design process shall ensure that the accounting data warehouse system of standardization and necessary contact. Each element has the following three steps: first, define the subject needed for details of each data source, including the computer platform, the owner, data structure, using the data processing, warehouse updated plan, etc. Second, define the data extraction principle, in order to extract the required data from each source. Define how the data transformation, loaded into the theme of which data table. In the end, will be a theme refining for multiple business theme, form the subject table, choose multiple data subset from the data warehouse accordingly.

These data definition direct input in the system, as metadata (metadata) storage, used for data management module and analysis. The metadata stored in the metadata repository, it is not only the documentation of the data warehouse, used for management, maintenance staff, and also for the user query, make it a better understanding of the data warehouse structure, raise the level of their use.

2, the accounting data extraction. Topics within the accounting data extraction is based on the metadata database table definition, data definition, data extraction rules defined for different heterogeneous data sources (including the database of different platforms, text files, HTML files, knowledge base, etc.) for cleaning, conversion, and the data again organization and processing, loaded into the data warehouse target in the library. In the process of organizing data from different sources, to transform data into an intermediate model first, and then move it to a temporary workspace. Processing data is to ensure that the target data in the database for completeness and consistency.

3, the accounting data maintenance. Accounting data maintenance is divided into two aspects of the target data maintenance and metadata maintenance. Target data maintenance is defined according to the metadata database update frequency and update data item update project task to refresh the accounting data warehouse, to reflect the change of the data sources, and to deal with time correlation. There are two kinds of update operation situation, the original data in the table is in the warehouse for some of the data update and create a new time interval data, because many of summary data and the data warehouse information elements, must complete summary, so as to ensure the consistency of all information.

Accounting data warehouse size is compared commonly big, from the beginning of the established shall ensure that its manageability, an enterprise may establish several data warehouse, but they can share a meta database on it management. First of all, from the yuan required metadata database query, then update the data warehouse operations, after the update, RMB will update records in the database. When running environment, structure of data source and the target data maintenance plan changes, need to modify the metadata. Metadata is an important part of data warehouse, metadata quality determines the quality of the data warehouse.

Data mining in the ADSS system including accounting decision-making needs, a large amount of data mining algorithm and 3 parts. Accounting decision demand is the early stage of the real data mining of work to clear, the clear goal of decision-making; A large amount of data is the accounting information system and related system operation after years of accumulated mass, in various forms of storage of data; Mining algorithm is one of the hot spot of current research, mainly around the new mining algorithms to solve specific problems and the improvement of mining algorithm. By the mining algorithm can form mining tools.

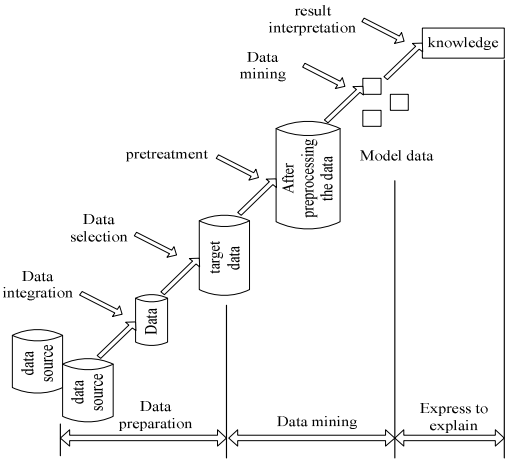

Fig2 Data mining

Knowledge discovery process may consist of three main stages: data preparation, mining operation, the expression and explanation, knowledge discovery is the three stages of repeated. As shown in figure 2.

Data preparation, data integration will be more data in a file or database runtime environment merge processing, solve the omission of semantic fuzziness, processing data and clean the dirty data. Data selection to determine the need analysis of the data collection, improve the quality of data mining. Pretreatment is in order to overcome the limitations of the current data mining tools.

Data mining:

1) to determine how to produce first assumptions. Is that the data mining system for users to produce hypothesis, or the users themselves may contain knowledge hypothesized reference database. The former is called found type (discovery-driven), data mining, the latter is called authentication type (verification-driven) of data mining.
2) select the appropriate tool.
3) data mining operations.
4) confirmed that find knowledge.

Results expression and explanation: the extraction of information analysis, through decision support tools presented to decision makers. This stage is not only give expression to the result, and knowledge discovery system will adopt interpretation and reasoning mechanism, the knowledge directly provided to decision makers, can also be provided to the domain experts, revision had been Shared knowledge base for the system. If not satisfied, need to repeat the process of knowledge discovery.

Summary

Data warehouse and data mining technology to provide decision support for the development of a set of systematic effective feasible solutions, it is a process of problem solving, rather than a software product can be obtained. Through the accounting data warehouse design, data extraction, data maintenance, accounting decision-making needs design, mining algorithm is designed, and the mining operation, the expression and interpretation, etc., can discover useful from vast amounts of financial data, important information, will push the further development of accounting decision support system, and continuously improve the decision quality and efficiency of the enterprise, for enterprise development, and leadership decision-making, etc. To provide scientific support.

Keywords: mobile police terminal, application warehouse system,application background, application front, information security

Abstract. In order to enrich the mobile police application and enhancing mobile police application security,analysis of current situation and requirement of the mobile police application,to put forward a kind of police mobile application store system based on information safety technology.Specific depicts system overall design,background design,front design,the use of information security technology,and the test results of the system are described.The design and development of the police mobile application warehouse system,have certain reference siginficance.

0 Introduction

With the development of science and technology,mobile police terminal function is becoming more and more powerful,mobile application more bearing,and due to the convenient and practical,mobile police terminal will be popularized in the police on duty.But how to make the application software of various new and useful rapid push to the arranged around the police,and realization application populated use the minimum cost and the fastest speed,and achieve rapid construction of information system,all of these have become subject to the information construction of police security system.Therefore the development of a system of policing in various kinds of application software for the authorization,unified management,flexible configuration,block push,makes the mobile police terminal can be convenient,safe to install application sofeware is urgently needed.Application warehouse system is designed in this background.

1 The design of the whole system

Application warehouse system is to provide secure signature authorization application software management and service platform based on ANDROID operating system of a mobile police terminal.From the application to create ,apply,examine,test run,release and off the shelf and other procedures to ensure application of the normal release.Application can be applied through users and user groups.The client can conveniently realize view application software introduction,application download,search application,evaluation application,application management,application unloading etc. function.The specific product diagram as Fig1 :

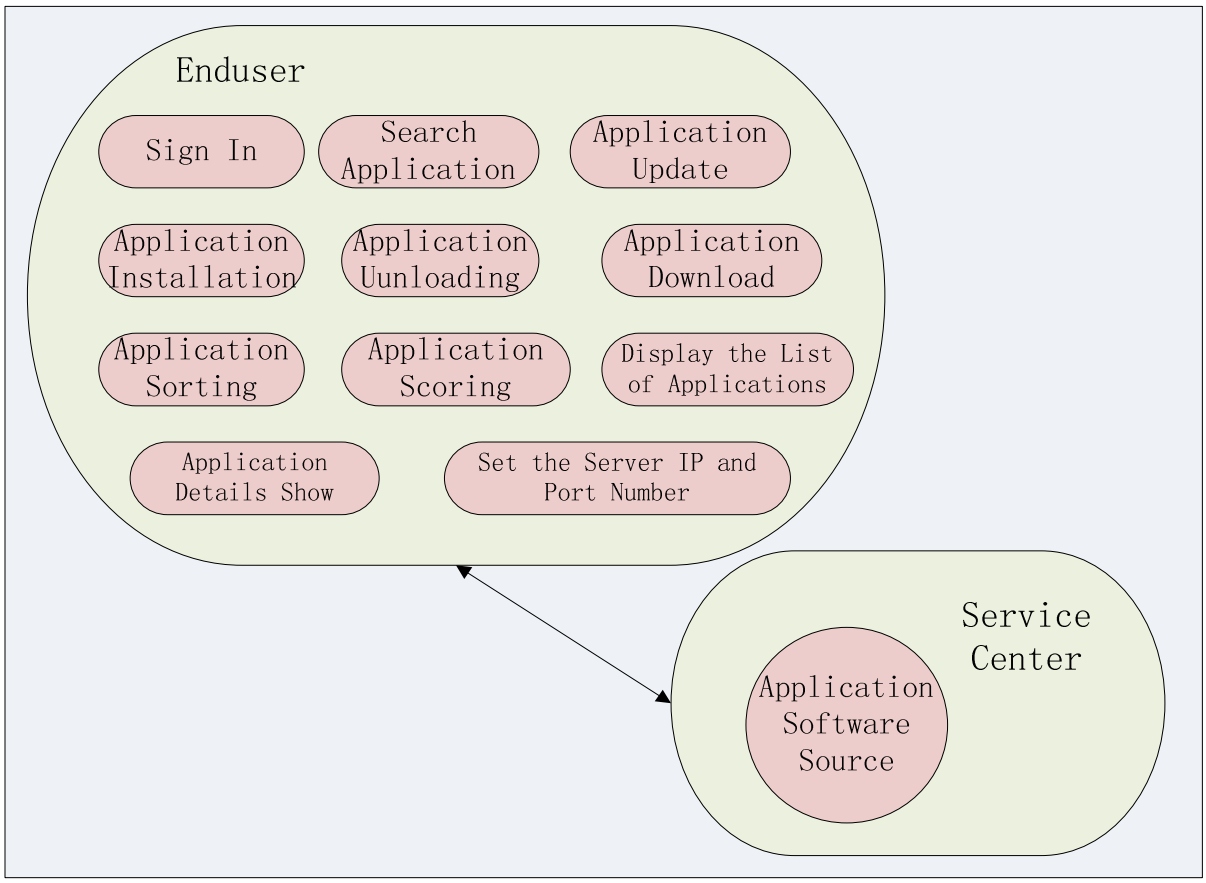

Fig-1

Application warehouse is designed with client/server structure,it's background is designed with SSH architecture,use JAVA programming language.The front-end client for any ANDROID operating system terminal,the APK file form.Now,client software can only support different versions of ANDROID operating system terminal.It's background software is composed of WEB interfacr,database and terminal event handing etc. function components,commom deployment on a single server,can also own distribution deployment,provide the performance of the system.The request of the system is initiated by the terminal application repository client software launched by HTTP,access the data of background,can be well compatible with the mobile access platform,system architecture specific as shown in Fig-2:

2 The design of the system background

The background is the core of application warehouse system,The design contains the following seven modules:

Processing the service request from the mobile terminal:the acceptance of mobile terminal upload application by request,accept the mobile terminal uploads the terminal application status request,acceptance of mobile terminal upload update application strategy of terminal request,accept the mobile terminal uploads the emergency service processing request application function.

Treatment of mobile terminal sends service request:to achieve remote control of mobile terminal equipment directive,the server of high security level message notifications.

User management:including the administrator application and business supplier business.

Develop application strategy:including the development of mobile terminal application offline strategy,strategy for mobile terminal application online.

DB:the use of ORACLE database,can not cluster.

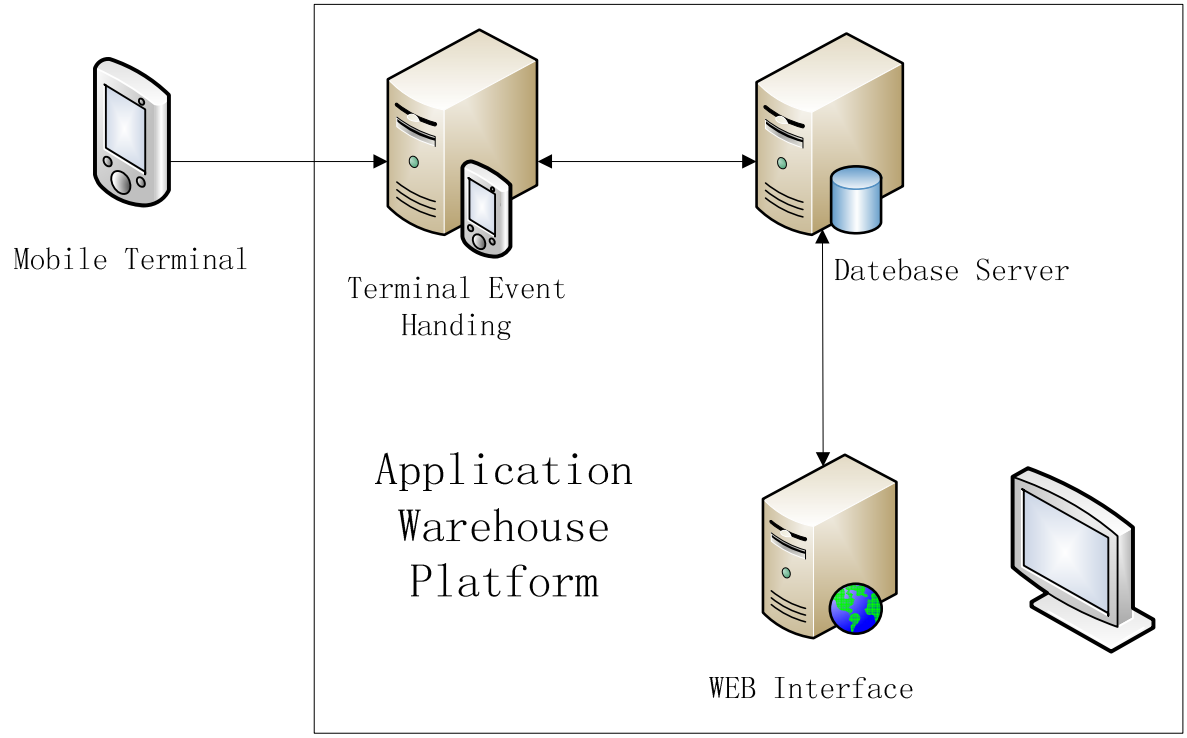

Fig-2

Analysis of application security access mobile and display:according to the input to the application of the warehouse information,analysis and applicaiton of safety state,according to the security filter condition display,display application security status,according to the application of security analysis,provides the application strategies or methods.

surveilance audit client:application log and data acquisition application warehouse,report and use data to the supervision and examination of cascade system,log and data warehouse application.

3 The design of the front-end of system

Application of the client in the ANDROID terminal in the form of APK,designed to contain such as several modules:view application recommendation,search application,charts,classfication,trial operation,management,application management,application setting,dowload details,scoring and evaluation version of history.

4 Information security technology used in system

1). Terminal Security Reinforcement

Through the terminal operating system and terminal OS reinforcement work along both lines,set up by the business layer until the kernel Stereo omni-directional integration layer of reinforcement.

2)Authentication of Application Signature

System uses proprietary tool needed to install the application for signature verification,to ensure that the appliction can be trusted,the validation does not pass refused to install the application.

3)Hierarchical Control of Application

Application of the warehouse system for unified management of the application of all operation,according to the operation needs and system safety.Requirements will be applied into mutiple levels,set up different security control measures according to different level.

5 Test Results

In this police application warehouse system,2 servers were used as the database server and application server,use the general ANDROID mobile phone,through the security reinforcement as

mobile police terminal and tested using remote security assessment system of green alliance.The test result is as follows:
1)Function test:The background and the front end of the functions is to basic achieve simple version of APPSTORE requirements.
2)Performance test:Through structure optimization and hardware performance improvement,number of concurrent users,online user number,terminal response time can meet the demand of actual combat.
3)Safety evaluation index test:The products have no high vulnerability through remote security assessment system of green alliance scanning mainly port.

6 Summary

This article from the current situation and demand of police mobile application,in-depth analysis of the overall design and application of warehouse system and the security technology.According to the design,application warehouse system of public security work put forward a set of terminal user management,application release,distribution,statistics,application system security audit in one,can solve the application fatigue and application security risk at present mobile police terminal face,has the importment practical significance.

A Study on Security Mechanism for Resource Identifiers in Ubiquitous Network

Minglang Jiang, Fang Cheng, Peng Zhang

Key Laboratory on Communication Networks and Testing Technology, Chongqing University of Posts and Telecommunications, Chongqing 400065, P. R. China

jiangminglang@qq.com

Keywords: UNRI; Resource Identifier; Security Mechanism; Ubiquitous Network

Abstract. Due to the openness of Ubiquitous Network, there is high risk for sensitive information leaked by users if any misuse of the resource identifier exists, regarding quantity, usage, storage, and content, which leads to a variety of security concerns. This article puts forward a means of protection against URI attacks in UNRI which is based on authentication, MD5 encryption and redirected URI. Through these methods, latent security threats can be guarded against effectively. Compared with other methods, the mechanism proposed by the author features shorter encryption time, yet more encryption parameters, which guarantees its wider application in ubiquitous business environment.

Introduction

As Ubiquitous Network implements information interaction through networks, resource identification becomes the author's first concern. For simplicity, "ubiquitous network resource identifier" is shortened to "UNRI" in this article. UNRI is mainly in the use of identifying logical and physical resources like data and services etc. in a unique way, and then managing ubiquitous network resources.

Related researches show that physical and virtual resources in trillion level interconnect to have formed a huge pool of resources, but scattered in a relatively independent state from each other. The independence of each system is caused by the lack of clear and interoperable standards for the classification and identification of key resources, coupled with a variety of heterogeneous networks, heterogeneous terminals and heterogeneous access. As a result, the situation brings significant barriers to UNRI, hindering interoperability between different networks and systems.

Web technology is an excellent example [1], anyway, Ubiquitous Network can take advantage of this for the basic interaction between systems, and data and power are taken as abstract resources, then identify resources in way of RESTful URI. Users can access to and manage resources with the proper permissions over the Web.

Related Work

As Ubiquitous Network is a huge network with variant degrees of openness, attacks against UNRI are endless.

In recent years, E. Du mentioned semantic URL attacks in the access links [2]. When users verify permissions, attackers can illegally obtain login password as well as other information by tampering request parameters. In 2011, G. Liu proposed that it is likely that other similar resources to be found and carried out illegal operations by attackers if the end of the identifiers allotted by resource management center cohere with the naming rules of resources themselves [3]. Meanwhile, G. Qin noted that URL attacks aiming at Web are mainly SQL injection and cross-site scripting (XSS) attacks [4]. SQL injection describes the problem that attackers can avoid oversight of systems and thus illegally access and manipulate resources in ubiquitous network by entering pre-designed SQL statements in identifier validation phase. While XSS could catch hold of the inaccuracy of program code, and embed illegal scripts into users' browser with maliciously structure resources URI included.

Moreover, R. Moskowitz. noted that ID and secret key are bound in Host Identity Protocol (HIP) scheme [6]. Thus it inevitably causes key expiration as well as other problems. Since the security of UNRI depends on the key and ID, expiration would bring great security risks, it is necessary to introduce effective mechanisms to manage its lifetime.

Considering the security issues pointed out in the previous studies, we shall introduce a new security mechanism based on lightweight considerations for UNRI. The author of this article presents a kind of security mechanism in UNRI which is based on authentication and MD5 encryption. By the protection of URI redirection, this method prevents attacks from many aspects, leading to a greatly enhancement upon the security of UNRI.

Security Mechanism for UNRI

REST defines the application standards of Web. Design based on RESTful for UNRI would make full use of the merits of Web-based architecture, and meet demands of integration and mashup of various identifiers. It also provides standardized and formative UNRI for different applications.

User Authentication and UNRI Redirection. Usually, UNRI applicants may choose whether to open to all or partially. If a user does not get access to the appropriate resources or UNRI is considered not credible by management center, resources can't be accessed or operated. Authorized users could use redirected URI which is distributed by Front Server (hereinafter referred to as FS) to access real resources, which to some extent, enhances the security of UNRI.

As for the security mechanism designed in this article, firstly the identification system servers are divided into FS that users can directly access to Resource Server (hereinafter referred to as RS) where resources are located. As shown in Figure 1, to access real resources, users need to visit one of the Front Servers for user authentication.

All user information is saved by FS. And users would obtain the redirected URI after passing certification. Then they could get real resource information from RS in accordance with the redirected URI.

In the process of generating each URI, FS would take advantage of account (FSId), assigned key (FSKey) and timestamp (FSTime) which records the generating time of redirected URI.

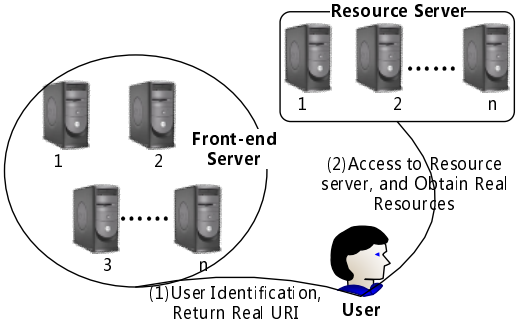

Fig. 1 UNRI System Access Diagram

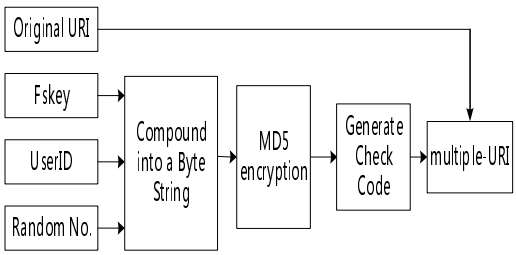

Fig. 2 Identity-based Redirected Resource URI

To ensure that ubiquitous network resource server receives a credible redirected URI, 3 ways are recommended here. Prevention of fake URI by public network users. Redirected URIs must be credible and returned by a FS. Prevention of accessing of expired URI. To prevent hotlinking, redirected URIs should have timeliness. It can be achieved by adding timestamp on URI request.

Prevention of fake URI by untrusted FS. Sometimes when a redirected URI or a certain FS is considered untrusted, system need to make a timely response to prevent accessing.

Since RS allows all authorized users to access and generally does not communicate with FS directly, thus authentication could be recommended. According to our proposed mechanism, we should first use MD5 algorithm to encrypt the URI request. Then we need take the synthetized URI with cryptography information to FS for verification.

If verified, FS will provide real resource URI to user and ensure that no same URI is available. The following part will elaborate the security mechanism in detail.

Generation of Redirected URI through Customized Encryption Function. We intend FSKey, FSId and some random number as parameters, and synthetize them in accordance with certain rules. Then we need to encrypt the compound string using a customized encryption function (MD5) and generate check code. Finally, as shown in Figure 2, we obtain real identity-based redirected resource URI after combining the check code with original resource URI.

Each user will get a unique ID in UNRI system, and different ID have different permissions. In practical applications, some of the resources must be accessed by authorized users.

To ensure the safety of UNRI, we add permission-auditing process in the mechanism and periodically change the FSKey.

In view of this, the redirected URI generated by customized encryption function is as follows:

…/FSId=***&uri=***&signmsg=md5(encode(uri,FSId,FSKey))

Upon receipt of the URI request, RS would determine whether the certain FS is credible or not on the basis of FSId. If FS is credible, then RS gains the FSKey from FS in line with FSId. Afterwards, RS will generate signature string in the same way as cryptographic signature process of parameters. Finally, compare the signature of redirected URI (signmsg) with a locally generated signature. If they are the same, the URI could be considered to be credible, otherwise illegal.

Implementation of Security Mechanism. As clearly illustrated in Figure 3, the implementing process of the security mechanism is elaborated as follows:

Step 1 Identify user in FS after the user login.

Step 2 Type in URI request to check existing permissions set to resources.

Step 3 Move to step 5 if there is no permission settings; examine the user's authority if there is any.

Step 4 Move to next procedure if user is permitted to access the resources, otherwise empty links will be achieved.

Step 5 Combine FSKey, random numbers, URI requests and user ID into redirected URI through a customized encryption function (here MD5 is in application).

The design and implementation of the mechanism, to some extent, have ensured the safety of UNRI. In fact, users can only access to real resources from the redirected URI. And furthermore, we shall make evaluations respectively after comparing this method with several other commonly used ones in the next section.

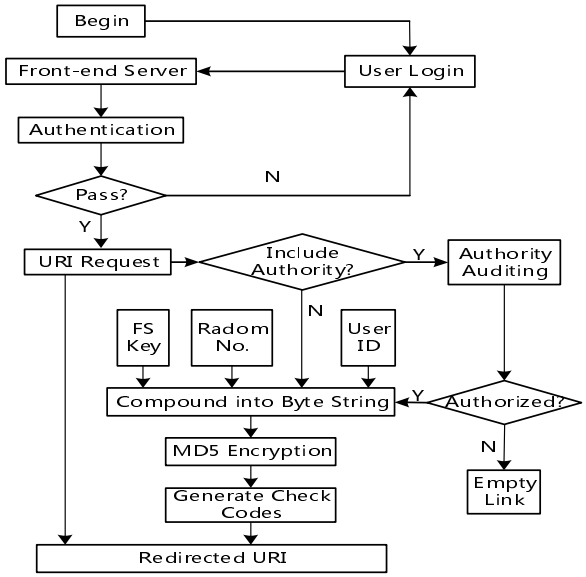

Fig. 3 Implementing Procedure of Security Mechanism

Evaluation of Security Mechanism for UNRI

As mentioned above, the security of UNRI has been heightened with a new security mechanism achieved by identity verification, customized encryption function and redirected URI. The other two

available methods for secure encryption are introduced below. A comparison between them and the previous one will be conducted in terms of encrypting time, parameters, etc.

Acquisition by Symmetric Encryption. In this method, RS firstly distributes different DES keys (FSKey) for different FS. Then des(params) will be acquired after FS encrypting the combined transmission parameters (including user URI request) in way of DES (a kind of symmetric encryption algorithm).

The redirected URI acquired by symmetric encryption is as follows:

…/FSId=***&desmsg= des(params)

Upon receipt of the URI request, RS would check whether the certain FS is credible or not on the basis of FSId. If FS is credible, then the DES key from FS (FSKey) would be achieved in line with FSId. Afterwards we need to decrypt the information of desmsg by means of FSKey. And we can't access to real resources if it ends in failure.

Acquisition by Asymmetric and Symmetric Composite Encryption. A key (des(params|FSKey)) is generated randomly by FS as the public key of the symmetric encryption algorithm. And rsa(key) would be achieved after RSA asymmetric encryption using the public key provided by RS.

The redirected URI acquired by asymmetric and symmetric encryption is as follows:

…/FSId=***&rsamsg=rsa(key)&desmsg=des(params|FSKey)

Upon receipt of the URI request, RS will check whether the certain FS is credible or not on the basis of FSId. If FS is credible, then rsa(key) will be decrypted in accordance with the private key from RS. Afterwards, according to the key gained above, des(params|FSKey) will be decrypted. Finally, RS will get FSKey from FS in line with FSId. Comparing the FSKey with encrypted FSKey, if they are not the same, the URI request would be considered to be a fake one.

Comparison and Evaluation. The public key of DES (a kind of symmetric encryption algorithms) is allocated in advance and may keep invariant for a long time. Thus the encrypted data may be cracked and fake request URI will arise once FSKey is available.

Comparing with single symmetric encryption, the use of asymmetric and symmetric composite encryption prevented key from being intercepted because public key should have been open to the public. Problem lies that receivers of public keys are not able to make sure whether the keys have been imitated or not.

Genuine and secret information has been concealed by the mechanism proposed in this article, which requires corresponding authority from users if they intend to access to the resources. Furthermore, MD5 has been very mature in encrypting which cannot be cracked so far.

Table 1 presents the comparison between MD5, DES and RSA in their encrypting process after which URI is redirected for UNRI. It draws the conclusion that redirected URI with MD5 is better than the other two methods in terms of performance. In addition, changing FSKey periodically will ensure the credibility of user's requests to a larger extent and guard against latent threats in a further step.

Table 1 Evaluation of Security Mechanism for UNRI

Method / Merit	Redirect URI with Symmetric Encryption	Redirect URI with Asymmetric and Symmetric Composite Encryption	Redirect URI with Customized Encryption
Features	Shorter key/lifecycle/ packet; Slower arithmetic speed	Secure; yet inefficient	Low-cost; Efficient
Encryption Times/s	30,000	17,000	62,000
Encryption Params	Less	General	More
Overall Merit	1. Long-term unchanged public key: possible to be cracked. 2. No guarantee against pass key not being intercepted.	1. Compound Encryption:avoid a single encryption intercepted. 2. RSA:no guarantee of the accuracy of the public key's sources.	1. MD5:most widely used Hash functions, uncrackable. 2. Redirected URI: Hide real information of resources, only authorize users can access to resources.

Conclusion

Being ubiquitous, capable, and inclusive consists of the 3 key features of Ubiquitous Network, with the intent of barrier-free communication by anyone, any objects at anytime, anywhere.
The security of UNRI is under threat as other heterogeneous networks join in. To solve this problem, a security mechanism is put forward by the author to prevent latent threats and illegal acquisition of UNRI. The author also conducted a comparison among the three means of encryption, after which URI is redirected, and proved the validity and practicability of the Security Mechanism.

Keywords: wireless sensor networks, intrusion detection, Ant-Miner algorithm, network simulation

Abstract. In this paper, we propose an intrusion detection program based on improved Ant-Miner (AM). The proposal needs to collecting out the node data, using intrusion detection module to test, compared with other wireless sensor network intrusion detection scheme, this scheme saves energy consumption of the sensor node effectively. Through the network simulation, this scheme proposed has a lower false positive rate and a higher true positive rate comparing with the current typical wireless sensor network testing program.

Introduction

With the rapid development and increasing sophistication of microelectronics technology, computing technology, wireless communication and sensor technology, Miniature Sensor, having the ability of perception, computing and communication, appears in the world. Wireless sensor network (WSN) [1,2] is a network which is formed by MANET manner by laying large numbers of low-cost sensor nodes to monitor and then through a wireless to connect. Perceive the cooperation between nodes, and monitor the status information of the target region, then transmit them to the users via the network. Wireless sensor networks are developed based on the basic technically of wireless communications technology, embedded technology and sensor technology, with the characteristics of low power consumption, low cost, distributed and self-organization, etc.[3,4].

Wireless sensor network has the characteristics of large-scale, self-organizing, multi-hop routing, dynamic, resource-constrained, data-centric and application-related, so it has been widely used in the fields of military, environmental monitoring, medical, industrial control, etc. [5], is the focus and the high ground in current international technological competition, has become a hot research at home and abroad. For the wireless sensor networks is more widely used in many fields in recent years, especially in some very sensitive areas, such as in military field, where the security issue becomes a very critical issue restricting its development [6], so the study of its security issues becomes more important.

Currently, the technologies solving wireless sensor security problem include encryption, authentication, secure routing, and secure data transmission, intrusion detection and trust mechanisms etc.. This paper studies an intrusion detection scheme based on improved Ant-Miner algorithm. Experimental results show that this algorithm has a lower false positive rate and higher true positive rate compared with the original testing program.

Ant-Miner Algorithm and its Improvement

Ant-Miner Algorithm Introduction. Parpimelli and his colleagues proposed Ant-Miner algorithm in 2002, the first time to solve classification problems using ant colony algorithm. The classification rules can be broadly described as: IF <conditions> THEN <class>. The Ant-Miner algorithm pseudo code is as follows:

```
Initialize: Training Set=all training samples;
    While (NO.of uncovered cases in the Training Set>Max_Uncovered_Cases)
  i=0;
Repeat
    i=i+1;
```

Ant_i constructs a classification rule incrementally;
Prune the just_constructed rule;
Update the pheromone of the trail followed by Ant_i;
Until (i≥No_of_Ants) OR (Ant_i constructed the same rule as the previous NO_Rules_Converge-1 Ants)
Select the best rule among all constructed rules;
Remove the cases correctly covered by the selected rule from the Training Set;
End while
End

In Ant-Miner algorithm, the information of all nodes is initialized to the same value:

$$\tau_{ij}(t=0)=\frac{1}{\sum_{i=1}^{a} b_i} \tag{1}$$

Where a is the number of attributes, i is the property label, b_i is the number of attribute value belongs to i-th attribute.

Each ant start with a blank rule, and then to construct rules, the probability of being selected for these attributes which have not been selected can be calculated by the following formula:

$$P_{ij}(t)=\frac{\tau_{ij}(t)\times\eta_{ij}}{\sum_{i}^{a}\sum_{j}^{b_i}\tau_{ij}(t)\times\eta_{ij}},\forall i\in I \tag{2}$$

Where η_{ij} is heuristic function of $term_{ij}$; I is the attribute set which have not been selected by the ants.

In Ant-Miner algorithm, the heuristic function is calculated based on information entropy, as following formula:

$$\eta_{ij}=\frac{\log_2 k-\inf oT_{ij}}{\sum_{i}^{a}\sum_{j}^{b_i}(\log_2 k-\inf oT_{ij})} \tag{3}$$

Where $\inf oT_{ij}=-\sum_{w=1}^{k}(\frac{freqT_{ij}^{w}}{|T_{ij}|})\times\log_2(\frac{freqT_{ij}^{w}}{|T_{ij}|})$, k is the number of classes, $\inf oT_{ij}$ is $term_{ij}$'s information entropy, $|T_{ij}|$ is the number of samples satisfying $term_{ij}$, $freqT_{ij}^{w}$ is the number of samples meeting $term_{ij}$ and its type is w.

In order to avoid over-fitting of the sample, we need to prune them after the rules generates. The idea for pruning rule: Repeat judge whether it increases the quality of the rule after delete a $term_{ij}$, if YES remove the condition, otherwise retain the condition until only one attribute node is left or it can not increase the quality after delete any attribute node, then the pruning rule ends. The quality of the rule is given by the following formula:

$$Q=(\frac{TP}{TP+FN})\times(\frac{TN}{FP+TN}) \tag{4}$$

Where Q is the quality of the rule; TP is the number of samples satisfying the rule antecedent and consistent with the type of prediction rule; TN is the number of samples dissatisfying the rule antecedent and inconsistent with the type of prediction rule; FP is the number of samples satisfying the rule antecedent, but inconsistent with the type of prediction rule; FN is the number of samples dissatisfying the rule antecedent, but consistent with the type of prediction rule.

After an ant completes the construction of a rule, the information of the attribute node appearing in the rule is updated as follows:

$$\tau_{ij}(t)=\tau_{ij}(t-1)+\tau_{ij}(t-1)*Q,\forall term_{ij}\in rule \tag{5}$$

In Ant-Miner algorithm, the volatilization of the information is achieved by dividing the pheromone worth of all conditions with the pheromone of the condition.

Improved Ant-Miner Algorithm. While Ant-Miner algorithm tests have proven to achieve better classification results, there are also some undesirable places in the pheromone update and the path selection. Aiming at these problems, we proposed optimized solutions about the pheromone update strategy and its deadlock problems.

This Ant-miner algorithm achieves a positive feedback mechanism and accelerate the convergence speed using pheromones, but it make the algorithm easy to appear premature stagnation. From the pheromone update formula, we can see that the increasing of pheromone τ_{ij}'s which are in the elected attribute node $term_{ij}$ is over-reliance on the feedback information of rules quality Q, while the pheromones, which are not in the elected attribute node, volatilize too fast. This mechanism is easy to make the algorithm converges to a rule prematurely, resulting in reduced prediction accuracy of the rules. In order to make a closer behavior between the update pheromone and ant foraging, In this article, we learn from predecessors who introduce pheromone evaporation rate ρ [7], volatilizing the pheromone in the selected attribute nodes, initializing the attribute node which are not selected.

$$\tau_{ij}(t) = (1-\rho) * \tau_{ij}(t-1) + \tau_{ij}(t-1) * Q, \forall term_{ij} \in rule \quad (6)$$

And after the completion of a rule construction, regardless of the pros and cons of it (quality), all the attribute node pheromone will increases included in the rule, then these attribute node is certainly more likely to be selected in the process of construction. But in fact, if the rules quality is poor, it should reduce all attribute node pheromone appearing in the rule to avoid these attribute nodes appear in the next one rule. Therefore, we modify the pheromone update method, after construct three rules continuously, compare the quality of these three rules, make pheromone feedback for the highest quality, give up the other two rules. The modified algorithm stress the rules of quality; and the quality of the build rules will determine whether the attribute nodes pheromone appearing in the rule increase, and whether the optimization is reasonable and effective.

Anther risk appearing in Ant-Miner algorithm is a deadlock. Through trial we can find that if there are a few records belong to the same class, and the value of their corresponding certain characteristics attributes values are more consistent, and different with other record eigenvalues, that is these records in this category have extremely strong correlation, so the heuristic function value calculated will surely bigger, they are more likely to be selected into the rules to be constructed in the next. But if the number of these few records cannot achieve Min_Class_Per_Rule, they cannot be elected to construct the rule, then it will appear the condition of only electing several properties, but not constructing, in the end the algorithm gets into an infinite loop.

In this paper, we use a method which deletes these attribute nodes, make the construction of rules skip these attribute nodes.

Simulation results

One of the key issues of intrusion detection systems is feature selection. It is not the fact that if we have more characteristic parameters, we may not get higher rate of intrusion detection, the number of extracting and processing characteristics parameters is not a linear relationship with the performance of classifier. To select the eigenvectors reflecting the state of the system is an effective method of improving intrusion detection efficiency. The most influential traditional data network intrusion detection system evaluation is DAPRA1998 which selected 41 properties. Because the sensor nodes have limited resources, we can only select a small number of features for intrusion detection. Literature [8] studied the relationship between the attacks and network traffic, selected the appropriate flow indicators representing various attacks. For DoS attacks, we select the number features to receive packets; for Hell flooding attack, we select energy features for packets sent; for selective forwarding attacks, we select two characteristics of the number of packets sent by routing error and the number of packets received by routing error. In this paper we select the WSN node

throughput, node packet loss rate, the energy consumption rate, the number of request packet, the packet average delay as the characteristic parameters of the intrusion detection system.

In this simulation, we use NS2, deploy 100 nodes in 1000m*1000m rectangular area. The MAC layer protocol applies IEEE802.15.4, which is designed for low-complexity, low power, low data rate short-range network; the network layer uses the LEACH protocol, the radio propagation model is two-ray ground model, the carrier frequency is 2.4GHz, the initial energy of each node is 2J, simulation time 300s. Considering the probability of node moving is small in wireless sensor networks, so the node movement is not considered in the simulation.

First, through the simulation of various attacks and normal conditions, we obtain the sample data, then train the intrusion detection module based on improved Ant-Miner algorithm.

There are mainly two performance indicators of WSN intrusion detection systems: detection rate, false detection rate. True positive rate (TPR) is defined as the number of sample attacks which are correctly detected divided by the total number of sample attacks; false positive rate (FPR) is defined as the number of sample attacks which are incorrectly detected divided by the total number of sample attacks. By analyzing the performance of WSN intrusion detection, we compare it with literature [8], in this literature the TPR is obtained by attack detection scheme based on traffic prediction (TPDD). Replay rate increases from 10% to 50%. Comparative results are shown below:

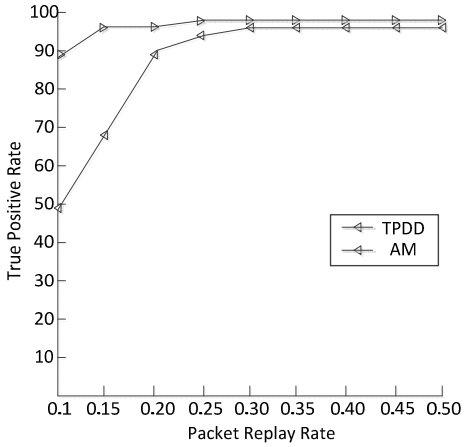

Fig. 1 Comparison of WSN true positive rate

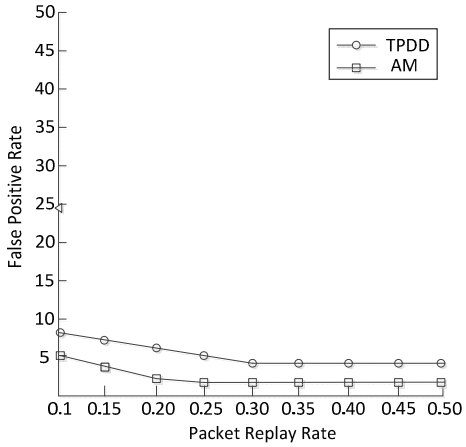

Fig. 2 Comparison of WSN false positive rate

From Fig.1 we can see that using the method in literature [8], when the attack strength is weak, the true positive rate is low. When we use the AM, we can obtain a high detection rate, thus this algorithm overcomes this disadvantage effectively. This is mainly due to our new intrusion detection scheme, in this scheme, we use five parameters which can effectively reflect the characteristics of the sensor network parameters, and establish the corresponding detection rules, rather than just detect the change of WSN-flow.

For another important evaluation criterion of false positive rate concern the performance of intrusion detection, we compare with literature [8], the result is shown above.

From Fig.2 we can see that our program has a low false positive rate than literature [8]. This is mainly because we have chosen more characteristic parameters, even if one characteristic parameter is mistaken for the attack characteristic parameter, the other four have not been mistaken for attack parameters, and you can still make the right judgments.

Conclusion

This paper analyzes the characteristics of wireless sensor networks, for attacks of the wireless sensor networks, we propose an intrusion detection scheme based on improved Ant-Miner algorithm. The program uses an improved Ant-Miner algorithm to detect algorithm, use NS2 simulation tool to model intrusion detection rules, and compare with the intrusion detection scheme based on typical traffic in WSN. The results show that the improved Ant-Miner algorithm based on for intrusion detection scheme has a lower false positive rate and higher true positive rate.

Keywords: Body area networks. Trust model. Key distribution.

Abstract. It is now possible to implant a network of sensors inside the human body for monitoring the human body functions and the surrounding environment. In a body area network (BAN), the confidentiality and integrity of the sensitive health information are particularly important. The key establishment is thus a fundamental security service in BANs. To guarantee validity of the key and avoid misbehavior of selfish nodes, we propose a fuzzy trust model for public key queries in BANs. Every user accesses the public keys of other nodes from those trusted neighbors rather than all of its neighbors. The proposed trust model uses fuzzy sets to calculate every node's trust value. Our trust model exploits multiple metrics rather than a single metric, and converts them into a single numerical ranking. We perform an extensive evaluation of the proposed approach. The results indicate that our trust model can not only identify abnormal nodes' behaviors, but can also reduce query traffic while improving the reliability of the returned public keys.

Introduction

The use of wireless sensors in health care makes it possible to monitor physiological vital signs, physical activities, as well as environmental parameters for human. They are used to cooperatively monitor physical or environmental conditions, which forms a body area network (BAN) [1]. What's more, a BAN has distinct features such as the mobility of sensors, and the sensitive nature of the data and the proximity to potential attackers [2]. These distinct features make it easily exposed to a variety of attacks such as eavesdropping, node compromising and physical disruption. In this paper, we design a light weight and flexible public key distribution scheme, which is based on a series of recent works in distributed key caching. For example, in [3], each node caches the public keys of a mix of local and remote nodes. If one node's public key is unknown, it is possible to obtain it from some chains of trusted nodes. Our scheme even takes into the consideration of selfish nodes in the network when they refuse to forward packets. In our trust model, every node can calculate the trust values of their neighbors. Selfish nodes will be given a small trust value. Key request messages are only transmitted to the trusted neighbors rather than to all of its neighbors. The benefits are two-fold: not only it reduces the number of control messages transmitted in the network, but also it improves the reliability of the returned public key.

A Fuzzy Trust Model for Public Key Distribution

In our fuzzy trust model, every node can calculate the trust values of its neighbors based on the neighbors' trust information. Some neighbors with higher trust values will be chosen to forward key queries. Our scheme can be divided into three stages: trust information observations, trust calculation and trust ranking.

Trust information observations. In this phase, nodes collect first and second hand information according to different trust metrics. We adopt four trust metrics: the probability of successful interactions, the success rate of exchanging, packet loss rate and battery energy.

The probability of successful interactions: The probability of successful interactions is chosen as the basic metric in many existing trust models and used to collect information about the packet forwarding behaviors of the neighbors. Every node, such as n_i, maintains two records for every

neighbor n_j, Ns_{ij} (the total number of packets sent to n_j by n_i) and Nf_{ji} (the total number of packets forwarded for ni by n_j). Then the probability of successful interactions between n_i and n_j, Psi_{ij}, evaluating whether n_j is honest enough to forward packets for n_i, can be calculated as follows:

$$Psi_{ij} = \frac{Nf_{ji}}{Nf_{ji} + \lambda(\mathrm{Ns}_{ij} - \mathrm{Nf}_{ji})}. \tag{1}$$

Success rate of exchanging: We use F_{ij} to denote the number of successful data exchange between n_i and n_j. If n_i receives a message from n_j, the value of F_{ij} will be added by one. Then F_{ij} is used as a metric to represent the trust attitude of n_i towards n_j.

Packet loss rate: A node is capable of overhearing its neighbors' transmissions in the promiscuous mode. It is assumed that n_j is overhearing a neighbor of n_i. Nin_i and Nou_i represent the total number of packets received and forwarded by n_i. Then the packet loss rate can be calculated.

Energy: In BANs, it is a very important issue to use energy efficiently, so the energy information of every neighbor can serve as a metric to determine the ranking order of the neighbors. In our scheme, we adopt the method proposed in [4] to detect a neighbor's energy.

Trust calculation. Based on the trust information from the first phase, we can adopt the method of fuzzy mathematics to calculate the trust values or trust levels.

To assign trust level to every node, four remark levels are defined, that is, $V = \{\mathrm{v}_1, \mathrm{v}_2, \mathrm{v}_3, \mathrm{v}_4\}$. v_1 means "full trust". v_2 means "relatively trust". v_3 means "general trust". v_4 means "not trust". Based on the trust degree of each metric, n_i can generate a matrix DT for every destination based on the first hand trust information, where DT_{ij} represents the membership degree of metrics i to comprehensive evaluation level j.

$$DT = \begin{pmatrix} DT_{11} & DT_{12} & DT_{13} & DT_{14} \\ DT_{21} & DT_{22} & DT_{23} & DT_{24} \\ DT_{31} & DT_{32} & DT_{33} & DT_{34} \end{pmatrix}. \tag{2}$$

Then, n_i can generate a matrix IT for every destination based on the second hand trust information. When nodes meet each other, they will exchange their DT matrixes. Then, n_i can combine other nodes' DT to generate a second hand matrix (IT) for every destination. Combining with DT and IT, n_i can get the fuzzy evaluation matrix R. Here, ω represents the weight of the direct information. Because the direct information is relatively important, we can increase the proportion of subjective judgment by increasing the value of ω.

$$T = \omega_{dt} \cdot DT + IT. \tag{3}$$

Finally, we can get the comprehensive evaluations as follows:

$$\begin{aligned} S &= W \times T = (\mathrm{s}_k)_{1*n} \\ &= (\omega_1, \omega_2, \omega_3) \times \begin{pmatrix} T_{11} & T_{12} & T_{13} & T_{14} \\ T_{21} & T_{22} & T_{23} & T_{24} \\ T_{31} & T_{32} & T_{33} & T_{34} \end{pmatrix}. \end{aligned} \tag{4}$$

In the formula, the weight matrix W represents weights of different metrics. Here we set W = {0.3,0.3,0.4}. T is fuzzy matrix and t_{ij} means the membership degree of metrics i to comprehensive evaluation level j. By calculating S, we can get a remark set of membership values for different nodes. Finally the trust level can be assigned to a node according to the following formula.

$$Vso_{ij} = \frac{\sum_{i=1}^{n} u(v_i) \cdot \mathrm{s}_i^k}{\sum_{i=1}^{n} s_i^k}, \quad U = \{4,3,2,1\}. \tag{5}$$

In the formula, $u(v_i)$ represents the remark of the four trust levels, meaning 4 represents v_1 and 1 represents the last trust level v_4. For example, if the final trust value is 3.1, then the trust level of the node is closing to v_2 which means it is relatively trusted.

Trust ranking. We use the trust levels calculated in Trust calculation and E_{ij} (the battery energy information) to determine the ranking order of all alternatives of neighbors. The trust ranking phase takes place when the node wants to forward a key request message.

$$F_{in} = \omega_1 * Vso_{ij} + \omega_2 * Energy\,. \tag{6}$$

Then according to the ranking order, the sender chooses the more trusted neighbors to forward the key request messages. The percentage of nodes may vary as the application changes.

Performance Evaluation

We use NS2 simulator in our simulations. We simulate a body wireless sensor network to evaluate our Fuzzy Trust Model for Public Key Query. We focus on the returned number of public key copies for the destination within a limited number of hops and the number of control messages for obtaining them. In our scheme, a balance between control messages overhead and public key copies is maintained by the control message forwarding rate.

We compare our designed scheme with two related schemes in overhead (in terms of number of control messages) and the number of key copies found. The two schemes include a caching scheme with no trust consideration [3] and a scheme with basic trust consideration [5]. In [3], all nodes are trusted. In [5], however, a basic trust model is used. Instead, our scheme considers all four metrics and uses a fuzzy model to combine them into numerical ranks.

Figure 1 shows the number of control messages transmitted in each key query. In the no-trust scheme, all nodes are trusted. Therefore, all neighbors are utilized to forward the queries, resulting in a large overhead. The basic trust scheme reduces the overhead significantly with the help of some trust relationship developed among neighbors. Our fuzzy trust model further reduces the overhead compared to the basic trust model as well as the no-trust model, demonstrating the benefits of its accurate trust relationship. When there are more and more selfish nodes in the network, the overhead increases because of the negative effect caused by the selfish nodes' dropped packets.

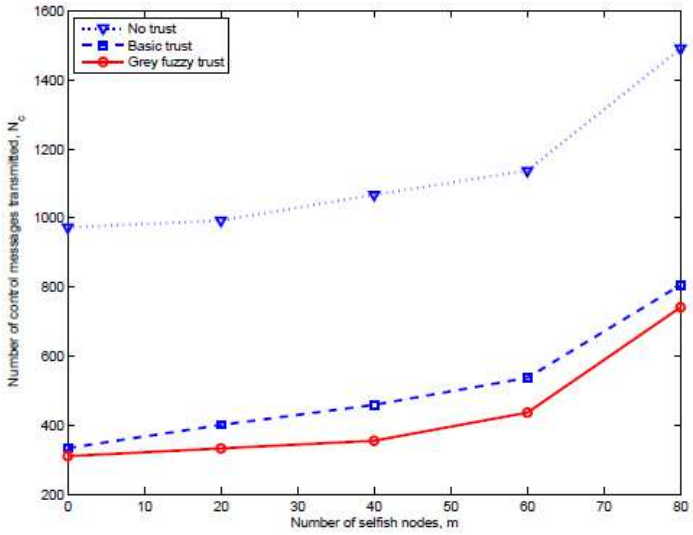

Fig. 1 Overhead in networks with different numbers of selfish nodes, m..

We show the copies of public keys found, K, in networks with different numbers of selfish nodes, m, in Figure 2. The trend of smaller number of copies found as m increases can be clearly seen from all three curves. As more and more nodes in the network become selfish, they refuse to forward key queries, reducing the chance of finding public keys. Another clear observation from Figure 2 is that the basic trust model returns fewer key copies than the other two, but the fuzzy trust model is able to

return roughly the same number of key copies as the no-trust model does. The sometimes slightly higher numbers might have been caused by the randomness of simulations.

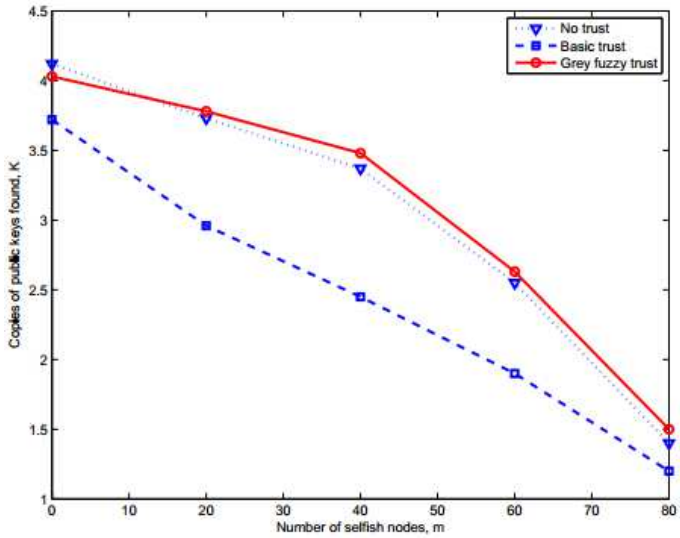

Fig.2 Copies of public keys found, K, under different selfish nodes, m

Summary

In this paper, we have investigated crucial trust issues in BANs, with the aim of guaranteeing validity of the key and avoiding misbehavior of selfish nodes. We have proposed a fuzzy trust model to allow nodes to rank their neighbors, based on the first-hand and second-hand information obtained from other nodes. Instead of using only one metric for trust evaluation, our technique takes advantage of four metrics: the probability of successful interactions, packet dropping rate, success rate of message exchange, and battery energy level. We have also exploited a novel approach of fuzzy to combine all four metrics into a numerical ranking for each node to choose a subset of neighbors to trust.

Keywords: The Browser/Server; Struts Framework. Fixed-line Lottery Ticket Sales System; Unified Payment

Abstract. The amount of fixed telephone service usage is becoming much bigger, and the using of the fixed-line to buy lottery tickets is more convenient. So exports have achieved a management platform of fixed-line ticket sale system branch in the Struts framework implements. The system based on B/S architecture and uses MVC (model-view-controller) design pattern. The system can realize the user for personal lottery ticket purchase information query and management. It's helpful for the administrator to unified payment platform of integrated information management. Under B/S architecture, the system uses the Struts framework design technology, which makes the system have good scalability, portability and maintainability. Users can use fixed-line ticket sale system in a more convenient and safe environment.

Introduction

Fixed line usage amount is decreasing, but the usage of the fixed line business is growing, so on this basis, we have added an electronic lottery sale business. That is using fixed line to buy lottery tickets[1]. A perfect function, it is easy to use and extensible fixed-line's Lottery sale system can greatly facilitate the users to use the system as well as Lottery betting station costs, but because of fixed-line has instability and poor visualization, so the sale management platform system is particularly important, for the information of the fixed-line's lottery system and payment platform management can improve the system availability.

The management platform of fixed-line's Lottery sale system can facilitates users to manage and query the lottery information, as well as provide a plan for each sale system's payment and management. System can be used in a number of marketing systems such as: ticket sale system, food sale system, and a variety of electronic ticket sale systems. Using b/s structure of the system so that users do not need to consider the client's hardware requirements, and using JSP+Struts+JavaBean framework make it easy to maintenance and upgrades of software in the future, to meet higher requirements may emerge in the future of the system's management. The system can provide perfect and humanized management services for managers .At the same time it offers for all types of sale systems with a user commonly used business services, so it makes the management platform system in all kinds of sale system which has a certain competitiveness. This paper introduces the management platform of fixed-line's Lottery sale system main techniques, design and realization methods.

MVC design pattern used in the development of the management platform

MVC's full name is the Model View Controller[2], a model - view - Controller acronym,and a software design paradigm for organizing code in a method of separating business logic and data, thereby so that the same program can use different forms of expression. The purpose is to ensure the existence of C M and V sync, once M change, V should be synchronized. This design pattern helps to enhance the program's scalability, reusability, maintainability, reducing development time.

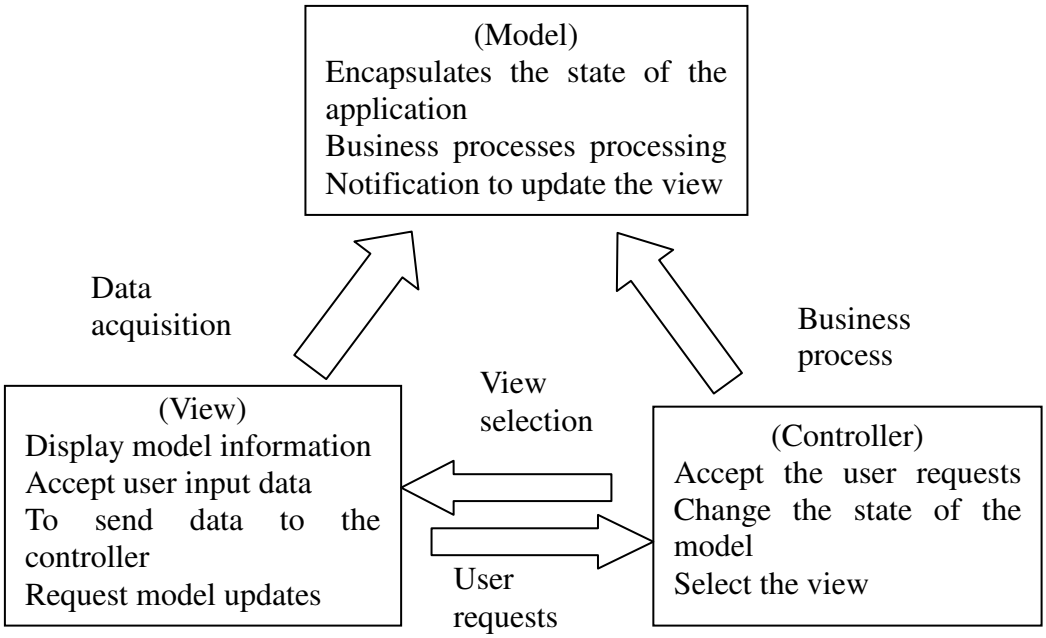

Fig.1. The flow chart of MVC pattern work

View: Display data (database records), the view is the user interface to interact with the terminal.

Model: representing the core applications (such as database records list), the model is the main part of the application, including business logic and data modules. Model objects are usually responsible for accessing data in the database.

Controller: process input (record into the database), typically read the data from the view controller is responsible to control user's input, and send the data model.

Specific process: the user enters data in the view screen, make a request, the controller receives user requests for processing and returns the data model, the controller calls the appropriate view output data, the user interface to view the output data through the view.

Design Management Platform of Landline lottery sales system

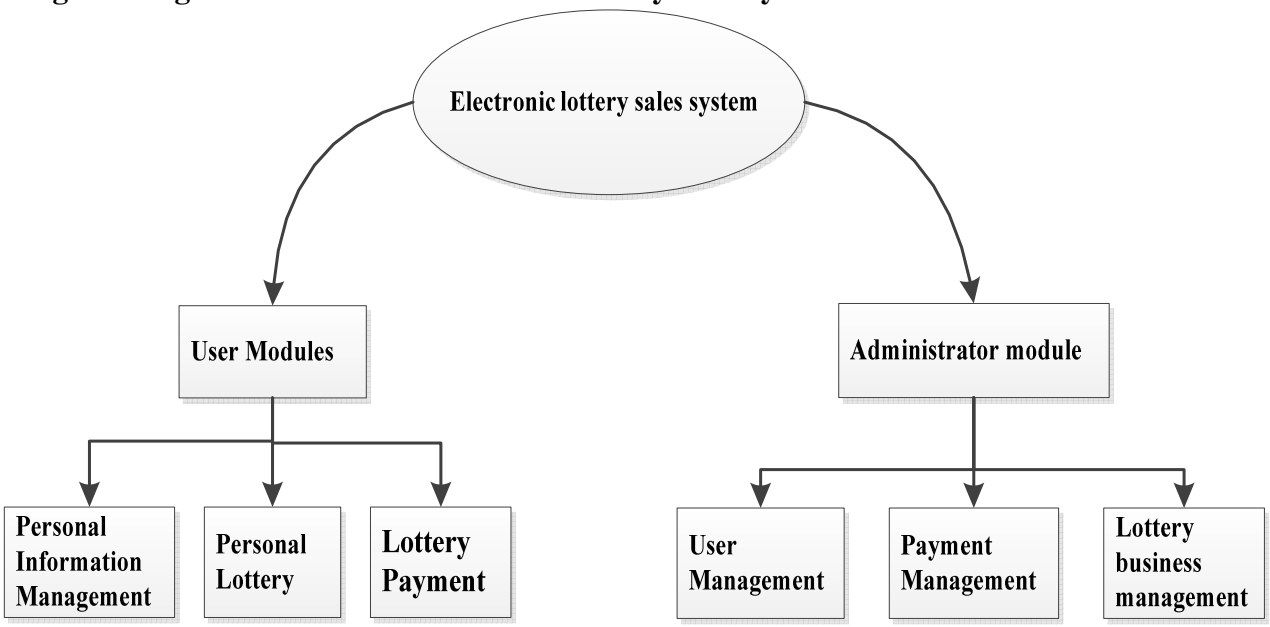

Fig.2. Pattern of the Electronic lottery Distribution System

The requirement and analysis of system. According to preliminary analysis of the situation of the lottery sale system,to meet the needs of users and managers,the system is mainly to achieve the following functions:

Login. For improving the comprehensive management ability, there are three types of people use the system, ordinary users, general administrator and super administrator, that will login the system according to the assigned user name and initial password.

The information management. Users can change their login password and other basic information.

Lottery ticket purchase information. Users can check to see the lottery whether they have purchased and drawn case of the day according to the their own lottery. And they can also check to see the payments and canceled unpaid lottery bet.

Business management of users lottery. Users can choose to subscribe to or apply for cancellation of the state of their business, the administrator or super administrator can handle the application that the users want to change the status of the business.

The management of unified fixed payment. Administrators can manage unified payment platform that is under the connection of the Fixed lottery sales system, to ensure proper payment.

Administrators to manage. Super administrators can perform account,cancel the account management to common administrators.

The management platform of fixed-line lottery slaes system allows this system can manage the purchase cases of fixed-line lottery better.Also provides users with accessing to personal information of lottery and to open new lottery business.

The design of user and administrator features modular

The super administrator has rights to manage common administrator, and to add or remove common administrator. The user modules added the individual fixed-line business management and ring tones' management, improving the utilization of the fixed telephone.

Database design. Demand for fixed lottery sale system through the contents of the fixed lottery sales management, data flow and analysis of basic information, as well as standardization of design requirements, The main database tables of this system include: user data table (cx_user), lottery business table (cx_phoneservice), lottery information table (cx_phonecalllog), lottery pay bills table (cx_addlog), fixed information table (cx_ring), the operation log table (cx_log), operating package table (cx_mealtype), Bureau of the user table (cx_device_cfg), fixed management table (cx_servicebill).

Each table in the database is connected to each other and provides valid data for the system, the final completion of the design of the database tables based on the relationship between each individual and the primary key of the table.

The implementation of fixed telephone cluster management system based on Struts framework

The workflow of Struts in system development. Struts is an open source project sponsored by the Apache Software Foundation.It is a classic MVC design pattern to achieve the application pattern of MVC design pattern,which uses the Java Servlet[3] and JSP technology.Struts is an object-oriented design, MVC design pattern "separate display logic and business logic" advantage to play the most.[4]Beacause of its powerful tag library,the efficiency of development has effectively improved.The adventages of its development framework is clear structure and stable performance,simplifying application development.In Struts, the controller achieved by the ActionServlet or Action; view constituted by the JSP page; model consists JavaBean or EJB components.Struts processing flow is as follows:

Users submit requests information and transmitted to the server by HTTP.ActionServlet,the central controller to the next step through the configuration file struts-config.xml,users fill out the form data to the corresponding ActionForm.According to the received request, the request is distributed to the appropriate processing Action.Action class called Model components to business logic processing.Finally, the controller forwards HTTP requests, call the appropriate view component to format the data returned by the model, the view component corresponding information presented to the user.

Build the platform environment. The system selected mysql[5] database as database applications, using tomcat6 as a Web application server,and using MyEclipse as a development tool, which integrates Struts components.

Deployment of the system. The role of system development model can handle data received form, based on business logic to process the request, and the output data to the view.The same model can be reused multiple views to improve the reusability of the application.In login module as an example, a user fixed cluster management system is divided into three categories: user, general manager, super administrator.In accordance with the user's login will be different privileges, enter a different window interface.Page displays using JSP technology, which is inserted into the Java program segment (Scriptlet) and JSP tag (tag) in a traditional web page HTML file.WEB application development with JSP can run cross-platform, regardless of the operating system restrictions.Since the MVC design pattern view layer and the business layer separation, thus allowing to change the view layer code without recompiling the model and controller code.The controller receives the user's request, and then decide which one model to process the request and configured jump page for displaying the output data.

After the project is completed, the next step for the deployment, use MyEclipse development tool or manually deploy the project on tomcat.On the server host, the appropriate configuration database data and the path is ready, users can access the system through a browser client in the end.

Conclusion

This system utilized popular Struts framework in the development of WEB applications, providi ng some design ideas and solutions for Fixed buy lottery tickets, and ultimately. Since the Struts has the advantages in web application development ,as the software upgrades and extensions are more convenient, it can be applied to different enterprises and institutions after slightly modified. Compre hensive traffic information management and business service are a great convenience to fixed-line u sers and managers to improve office efficiency. With the further development of fixed-line business and further tapping of the potential of fixed, fixed management system has a wider range of applica tions.

Keywords: Information retrieval, Crawler, topic

Abstract. With the rapid development of Internet, more and more information has been displayed to people. More and more researcher pay more attention to how to find useful information from this huge information ocean. We design the topic-oriented information retrieval system in order to overcome the drawback of generic crawler. The system retrieves topic information efficiently and helps user get useful information rapidly and exactly.

Introduction

Undoubtedly, it is the best way for people to get information from WWW. The current information retrieval (IR) systems, however, which aim at covering whole web pages has a challenge because web information growth rapidly and information environment is becoming more and more complicated. Firstly, magnitude of web pages expands too rapidly to index all of pages for IR systems, even Google which is the biggest search engine in the whole world presently, it only index 40% proportion of total web pages[1]. On the other hand, web information resource is change dynamically, so search engine, like Google, its average replacement cycle is extend as long as a month in order to maintain vast databases, this resulted in a certain web pages in pages retrieved by search engine are out of date or even cannot be displayed. Secondly, information services provided by traditional search engine cannot be satisfied with the increasing demand for personalization [2]. Therefore, research on topic-oriented crawler is becoming a hot spot in next generation of information retrieval.

Subject-oriented is only for a theme, a web page, such as literature, medicine, sports, music, MP3, software, etc., to collect. In other words is only collecting the subset of the network. It collects the web pages related to the theme of the pre-determined on the network selectively.

Topic, in other words is the type definition of user retrieval. It can be determined by a series of Webpage specified by the users, also can be confirmed by a series of feature words. Generally speaking, the user determines a series of samples collected Webpage firstly, determines the theme; then, analyzes samples Webpage, extracts feature information; Later in the process of collecting, according to the characteristics of information, for each collection of Webpage, a certain degree of correlation are given. The higher the correlation, means that the more similar to the topic.

Subject-oriented crawling technology is the core of the system to search the theme structure. Specific topics which study how to use crawlers have the option of access on the Internet, subject those and predefined related pages to download only in Web. These predefined topics are not only using some keywords, but also need to provide the sample document. Different from those who search for all Web pages, general search engine answers all the questions, crawler analyses of each link and determine which links to pages may be predetermined theme related to these links which will be crawled firstly and discard irrelevant links. Its goal is to collect as much as possible with a specific topic and Webpage, utmost ground avoids irrelevant Webpage download, to save hardware and cyber source are obvious meaning.

Focused crawling was proposed by De.Bra[3], the method of keyword matching to determine the relationship between simple Webpage through dual classification system. On this basis, M.Hersovici et al. [4] extended this method, considering the Webpage link anchor text relevance to Webpage in URLs according to the priority order, the relativity on the last page of the attenuation factor to succeed his father. Different methods of De.Bra, the method in the vector space model and can be arbitrary in 0 and 1 between the real values, and the anchor text and context to compute the similarity. J.Cho et al. [5] also improved the breadth first approach, improvement is not big, but the method by using the PageRank[6] method in the calculation of URLs priority weights. As the network information retrieval tools, topic crawling technology in recent years has been more and more attention of researchers [7-9].

SUBJECT-ORIENTED CRAWLER

Theme Confirm

The biggest difference is the qualified theme between network crawler subject oriented and general web crawler. How to define the theme is how a complete specification of the needs of users, if only the superficial told crawling to the Web page to find out about basketball, crawler may not know the one about Yao Ming whether the page should belong to this category; understand the crawler for the field of "Basketball" only the word "basketball" itself. When more complex, may the user need to find Web on the "Beijing" and "SARS", but does not include the "bird flu" page, this needs a good way to define the subject, to understand the user's interest.

The theme of the user input (a sentence or a paragraph text describing theme) input as a query to Baidu (http://www.baidu.com), then crawl down the first twenty Webpage given in Baidu, as a typical Webpage and related theme (training set). Then for the theme user input and training set grab obtained respectively, we do the participles, to stop words and word frequency statistics processing. After the extraction of high frequency words, delete of common words and meaningless words, use them as the relevant characteristics in this theme. This formed the two set, the corresponding subject content input by the user is the main key phrases, grab get training sector responding is the key phrase, which constitutes the foundation behind the judgment.

The Retrieval Algorithm of Topic Oriented

After the index has been established, preprocessing is complete. The inverted index and other related documents to the query node retrieval. For mass document retrieval, need a lot of server coordination calculation. At present the basic use of distributed computing to complete the calculation. When the user submits a Query to the server, the server will do some initialization work is transmitted to the computer to calculate the node, each node computer through calculation to find the most relevant K documents, back to the server, the server on all nodes of the returned documents ordered by Rank value, part of the ranking result is returned to the user.

The above is the basic approach of general search engine at present, so the back too many results, users find useful results into a dilemma. In fact, in general, from the understanding of Query point of view, if the Query is not strict enough ambiguity returns results may be closer to the needs of users, if Query is too loose may have many kinds of understanding, the understanding is returned will contain a variety of, then the user will take some time to find myself the desired results. If Query is "Andy Lau", the others in addition to the users are very difficult to judge what the user looking for information about Andy Lau, what about Andy Lau's film, or a song, or personal life. So if the retrieval system made the subject classification about Andy Lau information, then returns the results will show the Query related what theme, and the system will do the sort of theme in the relevant subject, recommended to the user which topics more relevant. So that the user can quickly find needed information by selecting the theme. Because after the users choose the theme, the returned results on the whole is the theme of the document. Of course, there may be a user looking for information relating to a theme, so that the user can respectively on the multiple themes do choose to find out useful information. So the topic information, can allow the user to find needed information quickly.

```
The algorithm of retrieval
Input: query
output: result of retrieval
procedures:
1. analyzing query;
2. segmenting for Chinese and stemming for English;
3. getting TermID after analyzing;
4.  allocating resource for every Term;
5. set int nResNum=0;
6. finding reverse list of every Term in reverse index
7. While (nResNum< the number of the retrieved result)
   {
        scanning reverse list;
        if (finding a relevant  document)
        {
          computing related values of the document;
          nResNum++=1;
        }
    }
8.  if  (nResNum< the number of the retrieved result)
    {
        finding reverse list of every Term in reverse indexing;
        While (nResNum< the number of the retrieved result)
        {
              scanning reverse list;
               if (finding a relevant  document)
              {
                    computing related values of the document;
                    nResNum++=1;
               }
         }
    }
9. if (the current is general retrieval)
   {
      finding the top N documents of the best weight in retrieved result;
      finding the DocID of  the N documents;
      return;
   }
   else
   {
       finding topic documents user demanded from retrieval results;
       finding the top M topic documents;
       return;
   }
```

Test Results and Analysis

In information retrieval evaluation on the retrieval effect standard accuracy, recall and average precision rate. But in the massive search engine by using approximate algorithm to search, so the evaluation standard is not the best estimate, questionable. And in information retrieval for standard text library evaluation, and for the search engines do not have standard Webpage database open for

evaluation. Therefore, for the evaluation of this system, we can make comparison with Baidu. Input Query and let Baidu do the search, the first 50 pages to download the Baidu results returned as a list of the system Webpage retrieval, then compare this system with Baidu's top10 or top20, see which one have a higher accuracy. Because here is the experimental analysis, the results showed that URL expressed in Webpage DocID.

In fact, the user using the search engines to look up information, in most cases, only view the content of the first two pages. So a search engine wants to retain customers, accuracy in front of him several items must be high. Therefore, in this sense, with the Top K index in the evaluation of search engine may be more meaningful.

Input "life career family" in Baidu, and extract the first 50 Webpage in the return results as the system data. The first 20 results of Baidu as shown in Figure 1, the retrieval time is June 4, 2007. The retrieval results of this system are shown in Figure 2 and Figure 3.

1. A new career, a new family, a new life Yang Yunqing shows a helmet
2. How to Balance Career and Family. If you are a working mom or dad
3. Use these simple tips to ensure a balance between the two most important things in your life
4. How to Balance Career and Family
5. Japanese work customs make it almost impossible for women to have both a family and a career
6. will not understand the value of the family. ? No career our life is blank
7. I used to be radical and thought one could not be a success in career
8. Career or Family: which is more important
9. career, family, and life satisfaction in three cohortsCatherine
10. Getting It Right: How Working Mothers Successfully Take Up the Challenge of Life, Family
11. family should be the number one in one's life
12. Have Breast Cancer!: Regain Control of Your Life
13. deem it more important to pursue their career
14. Life, Career, Family, Sexuality, and Faith
15. I am so grateful for the team and the opportunity to be there for my family
16. career can provide us with a means to live on. On the other hand
17. making their future retirement planning even more challenging than it already is
18. Career Advice for Life Scientists Women in Cell Biology
19. the family through marriage conferences
20. such as family and career Life

Figure 1 Baidu retrieval "life career family" top 20 results

For the retrieval results of Baidu, here to see more intuitive, listed only the title of the result documents. However the results of this system are shown as the retrieval result figure. From the lower left of Figure 6 shows that the retrieval time is 16 milliseconds. Here only to retrieve 48 documents because there are two documents not download, so only 48. The first 10 results in Baidu fourth and sixth little relevance. Because add the topic information in this system, so the foregoing documents in the search results are the high correlation.

The results show that the proposed algorithm compared with the general web crawler can be more significantly increase the number of the relevant Web pages, and improve the efficiency of the subject-oriented searching.

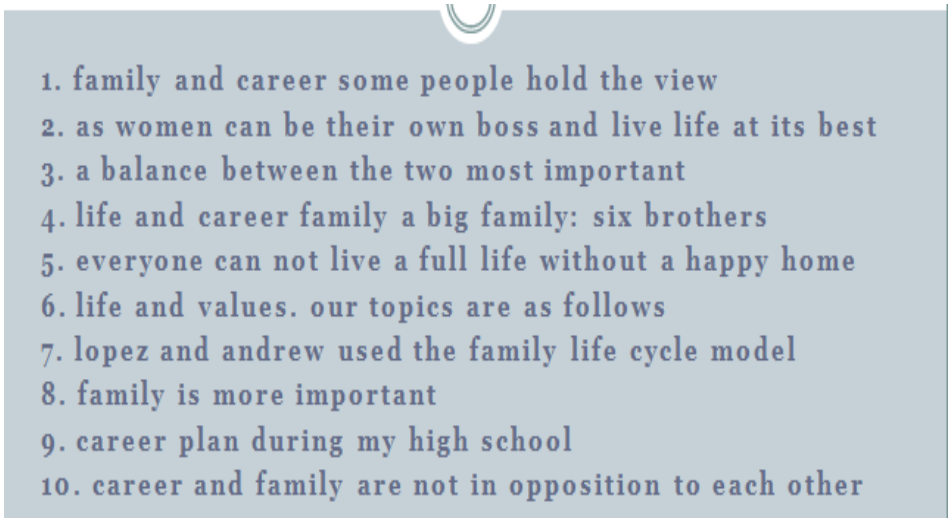

Figure 2 The retrieval system of "life and career family" top 10 results

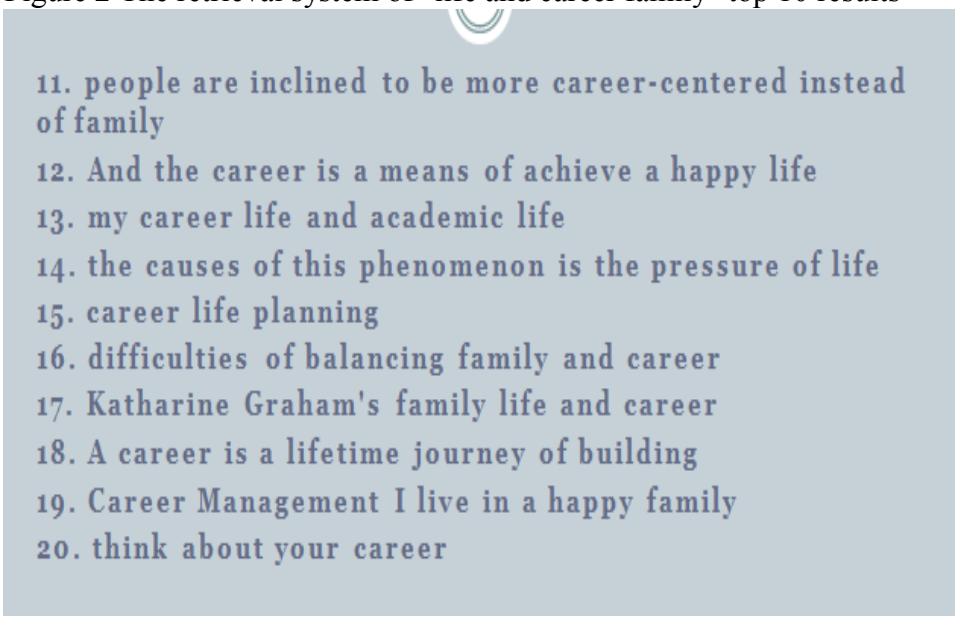

Figure 3 The system retrieval "life career family" eleventh to twentieth results

Keywords: Resource Representation, Resource structure, Software Evolution Process Model, Execution Model, Preparation for Resource, Knowledge Base.

Abstract. Software evolution process model (EPM) is a knowledge-intensive process which is described in EPDL(Software Evolution Process Description Language) and modelled by semi-formal approach based on EPMM(Software Evolution Process Meta-Model). In order to support process improvement and process automation, the execution model is represented by logic programming. Activity in EEM (EPM's execution model) is not implemented until its needing all kinds of resources are satisfied by system execution environment. The paper discussed the representations of all kinds of resources in EEM and their structures are proposed. The preparation resources method is presented in order to execute the EEM automatically. The converter program is realized and the correct results have presented to prove the correctness of the method.

Introduction

Resources are essential element in software evolution processes. Software evolution processes are very sensitive to the scarcity or abundance of resources. All data, cost, time, human resources, software, hardware, and other objects supporting software evolution can be regarded as resources [1]. Methods of resources' representations and managements are various with different application domain. Methodology of knowledge representation based on OWL is put forward to meet the requirement of integration management of enterprise resource [2]. Semantic converter which converts knowledge representation in Conceptual Graphs into representation in Resource Description Framework is designed to overcome the barriers in knowledge sharing and reuse due to lack of consensus of knowledge representation formats between these two knowledge representation models [3]. Instantiation policies as a compact formalism proposes are proposed and integrated to a process modeling language to allow user-defined reusable management strategies for resource instantiation [4]. Applying multiparadigm simulation modeling in the scope of two process areas with the aim of supporting decision making and determining the optimal values of cost and schedule according to the management needs [5]. Resources are encapsulated in components [6].Approaches above not mentioned the method of representing and preparing for the resources during executing software process.The paper proposes the method of representing and preparing for the resources in EEM. The preparation method of resources at process level, activity level and task level are respectively proposed. According, the paper is organized as follows. Section 2 review the relative research work about EPDL and modeling approach of EPM in [1]. Section 3 presents representation methods of all kinds of resources in any EPM. Section 4 presents the representation results of the resources in EPM's execution model using empirical data in case. Finally, Section 5 draws some conclusions.

Relative Research Work about Resources in EPDL and EPMM-based Modeling Approach

The structure of resources in EPM is represented with three levels in EPDL and EPMM-based Modeling approach.

(1) The first level resources are resources at process level which describe the partial order relations among activities. These resources are control information resources of activities in EPM. If an activity

has been provided with needing control information which is called precondition resources, the activity has the execution authority. The post-condition resources will be produced after the activity has been done.

(2) Activity can be a set of tasks. Any activity is defined as an abstract data structure which includes data structures and operations on these structures. The second level resources are input resources and output resources which respectively are described by imports data structure and exports data structure. Output resources of activity are generated by activity after its execution.

(3)The third level resources are local resources demanded by the tasks in activity of EPM at task level. Roles resources described local data structures are responsible for executing task(s).

The paper only considered the local resources such as roles resources. The activity can be executed only have three level resources been satisfied which are respectively the control information resources at process level, the input resources at activity level and local resources at task level.

Representation methods of all kinds of resources in EEM

Each type resource in three-tier resources in EPM can be described using a duality predicate "resource/2", which is resource(resourcetype, resourcetypevariable). The 'resourcetype' is used to denote type of resource, moreover the 'resourcetypevariable' is used to show variable of resource type, which is instantiated during running the execution model. Resource representation at three levels are respectively discussed below.

Resource representation at process level. There are two kinds of control resources that are precondition resources and post-condition resources. Each control resource has its name. These resources are expressed by the duality predicate 'resource(msg, resource's name)'. Using 'resource(msg, resource's name)' expresses the existence of this resource in execution system, while using 'not(resource(msg, resource's name))' shows this resource does not exist in execution system.

Resource representation at activity level. There are two kinds of resource which are respective system type and structure type used to express the import resources and export resources. System type are string type, enum type, et al. Structure type is defined by '*TYPE*' keyword in EPDL using system type and other defined structure type.

For import resources, each system type variable is expressed with 'resource(system type name, type variable(uppervariable))' and structure type variable is expressed with 'resource (strtype, littstruVar(X_1, … , X_m))', of which strtype and littstruVar are respectively used to express the structure type and structure variable with lowercase and X_j ($1 \le j \le m$) is name of the J-th domain of the structure variable with uppercase.

For export resources produced by activity, necessary information is provided by the role executing the activity. So Firstly, each string system type variable 'strVar' needs three sub-goals separated by comma in clause of Prolog. The first sub-goal is "write('Please input the value of lowstrVar')" prompting for the role information of input, where lowstrVar is variable name in lowercase. The second sub-goal is "read(uppstrVar)" receiving the input information by the role of executing the activity. The third sub-goal is "asserta(resource(string , lowstrVari(uppstrVar)))" adding the resource to the knowledge base. Secondly, each enum system type variable 'enumVar' also needs three sub-goals separated by comma in clause of Prolog. The first sub-goal is "write('Please input the value of enumVar，has $enumValue_1$,… , $enumValue_n$ for selecting')" prompting for the role selecting the value from set of enum. The second sub-goal is "read(uppeenumVar)" receiving the enum value selected by the role of executing the activity. The third sub-goal is "asserta(resource(enum , littenumVar(uppeenumVar)))" expressing adding the resource to the knowledge base. Lastly, each variable of structure type defined by user in EPDL need sub-goals which respective is hinting information, receiving the input information from the environment by the role executing the activity and adding the resource to the knowledge base.

Resource representation at task level. The important role resource indicating a person or software or hardware is described at this level in EPDL. For each role having a role name denoted by

RName, a sub-goal is needed which is "resource(role, lowRName (uppRName))" meaning to add the resource to the knowledge base.

The Method of Preparing for Resources in EEM

Resources Needing to Preparing for. There are two kinds of resources needing to preparing in execution model of EPM. The first are input resources which are not export resources of other activities. The second is each role needed by each activity for executing, but duplicate role only needs to be instantiated once.

Method of Preparing for resources. Those supported by the environment when resources are prepared are realized by informing the environment during running the execution model. In order to realize to prepare for the resources at activity level, the EPDL file is scanned twice based on the model transformation. The four kinds of information must be reserved during scanning first which are all STRUCTURE types and all domain names and types of those domain names defined in EPM and denoted by 'TypeSet', input resources of all activities denoted by 'IRSet', export resources of all activities denoted by 'ESet', role resources of all tasks denoted by 'RSet'. The resources of set denoted by 'InitIRS' which is determined by the formula (1) are prepared.

$$InitIRS = IRset - ESet. \quad (1)$$

Presenting the Resulting of representation and preparing for resources in EEM

ISO/IEC 12207 standard [7] describes the maintenance process model in software life cycle. Tong creates the EPM of this process in EPDL[1]. By method above, resources prepared for this EEM are described in prolog and listed in Table 1.

Table 1: Resources prepared for this EEM

```
resource(msg,start).
resource(requirements_type,requirements(proreports,modifireque)).
resource(string,problem(problema)).
resource(string,problem_report(probreportfile)).
resource(string,modification_request(modifreqfile)).
resource(string, original_requirements(origrequirmentfl)).
resource(string, contract(contractfile)).
resource(string,migration_request(migrrequfile)).
resource(string,iso_iec12207_standard(iso12207file)).
resource(system_type,old_system(docfiles,datafiles,progfiles)).
resource(string,retirement_request(retirereqfile)).
resource(system_type,new_system(docfiles,datafiles,progfiles)).
resource(role,pm(alice)).
resource(role,prm(michale)).
resource(role,dr(michy)).
resource(role,ma(alice)).
```

Conclusions

In this paper, representation methods of all kinds of resources in any EEM are proposed. The preparation method of resources at process level, activity level and task level are respectively

proposed. The converter program has been realized and the correct results have presented to prove the correctness of the method.

Abstract. This paper Based on the composition, types, functions and applications in the field of geographic information systems, analyzes the advantages of GIS technology in environmental impact assessment. From the project environmental impact assessment (EIA) of the limitations of departure, outlining the current status of the EIA study, while an overview of the geographic information system (GIS) functionality and applications, focusing on the status of the application of environmental impact assessment in the field of geographic information systems Necessity and Prospect. And use some of the existing management and analysis of environmental monitoring information system based on GIS examples further illustrate the application of GIS in Environmental Monitoring Data Management Analysis, give full play to the advantages of GIS spatial information processing and comprehensive analysis of expression, making the environmental monitoring data more effective.

Introduction

Environmental assessment is a commentary on the pros and cons of Environmental Quality is based on certain evaluation criteria and evaluation methods to determine the scope of a regional environmental quality, forecasting trends and evaluate the impact of changes in environmental quality of human actions on the environment. Environmental assessment is an important branch of the scientific basis for environmental science disciplines, new developments; environmental management is an important means to achieve a comprehensive environmental management.

With the wide application of environmental assessment EIA development and computers, computerized EIA standardization is to improve the overall level of environmental assessment requirements, but also the inevitable trend of development of the EIA. Computer Applications in EIA also from the simple to the complex process of continuous development. In the EIA computer technology can be used to store and process the basic data, EIA management, environmental monitoring and management. GIS data processing, analysis, powerful computing, recognized by our users. GIS analysis using powerful three-dimensional and three-dimensional display capabilities for environmental quality monitoring data obtained various evaluation methods to select a single element of a comprehensive evaluation of regional and automatically complete analysis and evaluation of factors to calculate the output results of evaluation and assessment, and application-specific analytical procedures, the spatial distribution of the contaminants in the image contours visually displayed, help to understand the spatial distribution of pollutants regularity; their data can generate pie charts, bar charts and other manifestations. Resources and Environmental Asessment as one of the major areas of GIS application, the application can greatly reduce the workload, speed up the evaluation process and to facilitate the evaluation of the results of dynamic management, updating and applications.

Research Status

Since the 1970s, the United States Tennessee Valley Authority using GIS technology to process and analyze a variety of watershed data, provide decision services for watershed management and planning, GIS had been used in hydrology and water resources management. Colorado's some agencies jointly developed the Colorado River Decision Support Systems, GIS is used to store basin space, retrieval, analysis and display. A research team of the University of Utah using GIS

technology to areas bordering Mexico and the United States carried out an environmental impact assessment, the establishment of surface water and groundwater pollution path model, and has resulted in the economic development of the region by GIS spatial analysis functions (such as buffer analysis) environmental impact analyzes; HECHANSHENG comprehensive evaluation of the impact of non-point source pollution of river water quality MICHIGAN CASS State GRASS software in support of the next; VENTURA, such as the use of GIS for urban non-point source pollution were analyzed and evaluated, combined with land use distribution type of control measures to provide basis for decision making. United States national, state environmental agencies and pollution control department developed the BASINS program. BASINS full advantage of recent developments in software, database technology and computer functions, and using Arc View GIS software as integrated watershed data to the entire United States, watershed analysis and water analysis software to unify, to provide users with an easy-to-understand , the point source and non-point source watershed management tool to unify. [1]

Institutions in some European countries to jointly develop a decision support system for watershed planning process simulation with hydrology, water pollution control, water resources planning and other functions / WATERWARE0, the system utilization of GIS, database, simulation, optimization procedures and expert systems function. GIS is mainly used for storage basin for all spatial information, providing data for the simulation system is also used to display the results of analysis and simulation.[2][3]

The Feasibility of the Application of GIS in EIA

GIS spatial database, spatial data and spatial expression analysis of three aspects of GIS may be widely used in environmental monitoring.

GIS Spatial Database to Achieve Effective Management of Environmental Monitoring Data

The main results of the environmental monitoring of environmental data , environmental monitoring continuity features make environmental monitoring data of tens of thousands each year , so the vast amounts of data is difficult to rely solely on manual management to ensure consistency and accuracy of the data . Establish an environmental monitoring database. The traditional structure of the database is not well expressed, storage information, can not be achieved and spatial information analysis and management of spatial data. Solving environmental problems must be combined with the reality of geospatial information. GIS database is a collection of some characteristics with certain geographic features are stored together in the area of organization of the relevant data. As the GIS database with large amount of data , spatial data and attribute data are inextricably linked , and has a significant spatial data between topology and other characteristics , so GIS database management features to environmental monitoring, in addition to the monitoring point attribute data related outside the DBMS functionality also includes management techniques for monitoring point spatial data. For example, the spatial location of monitoring sites and monitoring information retrieval environmental factors, such as retrieving and location monitoring points from the environmental quality control conditions.[4]

GIS Vivid Image Representation

GIS has very powerful graphical display and map making capabilities. But by no means just a mapping tool, it is geographic information about the environmental pollution monitoring, environmental management, and environmental factors such as geographical features combined analysis system. Data visualization of expression and maps, tables and graphs, and also the implementation of dynamic coupling between them, manage, and query, so a lot of abstract, boring data becomes vivid, intuitive and easy to understand. Electronic map visually interact with the user, the user can rely on the inherent human understanding and logic operations data for the natural world. Especially in recent years GIS application and development of virtual reality technology for the study of the spatial distribution of environmental pollution dispersion law provides an accurate, intuitive visual display, as well as real-time, dynamic display changes in environmental conditions.[5]

Integrated GIS Analysis Functions

This technology was developed by computer technology GIS and spatial data generated by the combination, which includes a variety of advanced spatial information processing capabilities, but its basic function is to collect data management processing, analysis and output. Rely on these basic GIS functionality through the use of spatial analysis, model analysis technology, network technology and database and data integration technologies, such as the interpretation of the secondary development of a variety of applications. It is precisely because GIS has such a powerful spatial data management capabilities and comprehensive analysis of spatial data, while 85% of the above-mentioned space-related environmental information, making it the management to analyze and solve environmental problems environmental monitoring data more superiority. Another combination of GIS and environmental models provide a more efficient and professional handling capabilities. Therefore, the analysis techniques to achieve comprehensive information processing environment is also necessary and reasonable use of powerful GIS space.[6]

The Main Application GIS in Environmental Monitoring Data Management Analysis

GIS biggest feature is the ability of the whole or part of the Earth's surface (including the atmosphere) the geographic distribution of the data space for the collection , storage, processing and management of information management, computation , analysis and visualization , spatial and attribute information has been able to for reprocessing , draw scientific conclusions. It is these features make it possible to combine with environmental monitoring, another angle GIS intervention makes a variety of environmental issues and environmental processes described in more realistic, interactive and friendly interface, easy spatial analysis, intuitive and vivid results display so undoubtedly promote the development of environmental monitoring technologies.

Environmental monitoring is accurate, timely and comprehensive picture of the status and trends of environmental quality, provide a scientific basis for environmental management, pollution control, environmental planning. Specific environmental monitoring purposes can be summarized as follows:

(1) According to the environmental quality standards, evaluation of environmental quality.

(2) According to the distribution of pollution, track looking for sources to provide the basis for the realization of supervision and management, pollution control.

(3) To collect background data, the accumulation of long-term monitoring data for the study of environmental capacity, the implementation of total control, goal management, forecasting environmental quality to provide data.

(4) to protect human health , environmental protection, rational use of natural resources , the development of environmental regulations, standards , planning and other services. Articles based on environmental monitoring purposes, divided into environmental quality monitoring, pollution supervision and monitoring, emergency monitoring three aspects to further illustrate the application of GIS in Environmental Monitoring Data Management Analysis. GIS spatial data storage and visualization of expression is a basic GIS functions , for any purpose in the form of environmental monitoring data will be used in all of the following three aspects will not bore you tired , mainly from the following GIS angle and comprehensive analysis of spatial analysis capabilities to illustrate the application of GIS.

Environmental Quality Monitoring

Environmental quality monitoring is the core monitoring. It is the pollution of the environmental elements of the situation and trend monitoring of pollutants, was evaluated to determine the effect of control measures and improvement of environmental standards implemented environmental progress achieved, the accumulation of quality monitoring data to determine the status of a certain area and the development of environmental pollution trend.

Environmental quality monitoring in general is for areas (such as basins, urban, etc.), and the region's air, water, noise, solid waste and other sentinel, long-term, long-term monitoring to determine the sources of the status quo in the region objectively comprehensive evaluation of the contaminated area to reflect the extent and spatial distribution. Environmental monitoring data are

usually obtained data on the number of discrete points in space, how to use these discrete monitoring data quality of responses to the real environment. Here you can use the interpolation method of GIS spatial data. Spatial interpolation of data can simply be described as follows: a set of spatial data set, they can be in the form of discrete points, the partition may also be in the form of data, these data are found from a function formula that changed the relationship The best approximation of these known spatial data, and can infer the value of any point within the region, or any other partition change function according to the relationship. [7]

Pollution Monitoring

Pollution monitoring is routinely monitored in order to grasp pollution monitoring, surveillance and monitoring of major sources of variation in space and time taken regularly sentinel. It is mainly the concentration of pollutants, the total emissions and pollution trends monitoring, pollution monitoring network to take advantage of trends and conditions of a region predict, forecast. Impact assessment of pollution on the environment, in addition to the concentration and amount of access to sources of emissions data, but also must rely on space background information sources where the geographical environment, the same pollutant emissions, because they are in a different location (including meteorological, terrain conditions, etc.), the degree of pollution and scope will vary. This is characteristic of geospatial sources. Geospatial characteristics determine the effect on pollution sources must be integrated geographic analysis of quantitative thinking and spatial analysis tools combine - Geographic Information System (GIS). Not only to conduct quantitative analysis of sources, such as the calculation of the size of emissions, but also to perform spatial analysis, such as calculating the relationship between emissions and ambient concentrations.

GIS spatial analysis of sources of pollution dispersion buffer impact analysis provides a powerful tool. Buffer space is analyzed based on analysis of the object point, line, and plane entity created automatically ribbon area around them at a distance, to identify these entities or subject scope or impact of the radiation on near objects. Here the application mainly in accordance with the position of sources (weather conditions, terrain conditions) model combined with the environment, such as calculating the degree of impact on near objects, draw a buffer zone to the performance impact of changes in scope and concentration of pollution sources, total control of pollutants, reduction program developed to provide decision support. For example, buffer analysis and path analysis can be used for a variety of elements that contains the figure and close analysis, analysis of pollution discharge destination, showing sources of influence, combined with pollution monitoring data, analysis and evaluation of emissions which contribute to the pollution of rivers rate (see Figure 1).

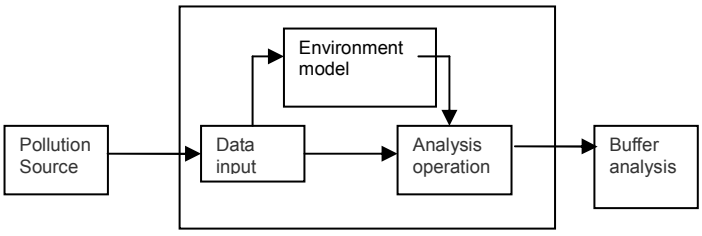

Fig.1, Buffer analysis of pollution sources

Emergency Monitoring

Emergency Monitoring is also known as monitoring a particular purpose, according to a specific purpose and can be divided into the following four categories: pollution incident monitoring, emergency monitoring carried out in the event of pollution incidents in order to determine the type and extent of contamination hazards, diffusion direction, the diffusion rate and endanger the range, provide the basis for the control of pollution; arbitration monitoring: mainly for pollution accidents disputes, conflicts in the implementation of environmental law arising monitoring; assessment verification monitoring, including environmental appraisal staff assessment, method validation and new projects and pollution Acceptance Monitoring governance projects when completed; consulting

services monitoring: government departments, research institutions and production units monitoring the services provided.

Pollutant monitoring and emergency pollution accidents are a variety of on-site monitoring to track, find out the degree of contamination and the scope of its accidents, damage caused by size. Environmental pollution dynamic continuous monitoring of major pollution incidents and respond quickly, Environmental monitoring is an important direction of development in order to implement effective pollution accidents have emergency requires the use of geographic information system technology to conduct a comprehensive analysis of relevant data and methods to first determine the location of the accident, and then use a combination of GIS and environmental models range forecast affected area to provide sensitive units within the contaminated area through GIS visualization, rescue units, population, and the best path from the accident site to the designated location and other information for emergency monitoring, carry out emergency rescue work to provide basis for decision making . , GIS spatial analysis used here as shown in Figure 2 the main buffer analysis, spatial data analysis and queries, and a collection of network analysis.

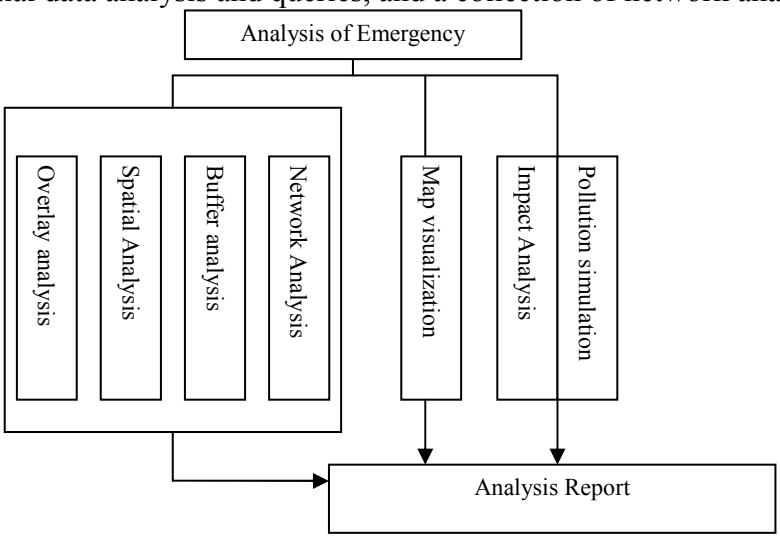

Fig. 2, Pollution Accident Analysis

Buffer Analysis

Buffer Analysis former already mentioned, the use of buffer diffusion and impact analysis and environmental pollution accident prediction models affected by a combination of regional and range, but can also affect the results of the analysis of the diffusion of rendering to visualize the concentration of contaminants or degree of impact.[8]

Query Spatial Data

Database query spatial data areas are generally defined as to identify all the properties to meet space constraints and the constraints from the database of geographic objects. Property constraints and traditional database query is similar. Space constraints with space for expression described by the predicate logic, spatial predicate by the spatial relationships between objects evolved geography , such as contain , intersect, separate , overlapping, distance and direction . Therefore, the role of spatial query function on the library body, returns the contents of the user's request, also belong consultative analysis.[9]

Conclusion

Temporal GIS, such as three-dimensional GIS and WebGIS from these new GIS technology and development not only extends the GIS own connotations, and no doubt it will also promote innovation in the field of environmental monitoring technology. Such as three-dimensional dynamic time series studies demonstrate GIS spatial data, which has the same area or a particular object change over time at different phases of geographic data to study the spatial variation, and in the form of three-dimensional animation on display. The results of environmental monitoring will bring a qualitative leap, not only that, if combined with a professional environment model in

environmental pollution forecasting, simulation, and emergency and other aspects will also improve the performance of the three-dimensional form of the model, improve operational efficiency model, making management analysis of environmental monitoring data more quickly, real and effective. With the development of GIS technology, GIS application in environmental monitoring data management analysis will also get an endless supply of the driving force.

Keywords: Remote maintenance; Equipment; Common platform; Browser \ Server; VIRTOOLS;

Abstract. In the analysis of the development and the functional requirement of the network-based maintenance training system, combining the long-distance maintenance service and virtual reality technology, the long-distance maintenance service based on Browser\Server has been founded, and the system architecture, key technologies and implementation methods have also been researched and discussed. The system will provide a powerful technical support platform for carrying out long-distance maintenance service.

Overview

With the development of science and technology, the contradiction between the increasing trend of high-tech equipment and the inadequate maintenance force which adapts has become more prominent. Interactive device remote maintenance system based on network being used to guide the remote user's equipment maintenance can maximize authoritative technical experts to share and off-site training of personnel. It will play a unique role in major equipment repairs, reducing maintenance costs and maintenance and technical personnel training. This is an urgent research topic in the actual maintenance of equipment.

Remote maintenance is the electronic transmission of data or information between the maintenance personnel and remote staff or sources of information. It can make the field service personnel prepair spare parts and tools timely before the return of equipment to perform tasks according to real-time transmission of equipment information, or get maintenance training and guidance in the field. And then ,when the equipment is returned ,it can be repaired immediately. Through the transmission system, the maintenance personnel in the field can get technical guidance and maintenance information from the rear base. Remote maintenance can not only ensure maintenance of high quality in the first time, but also within the effective time, improve the level of skilled maintenance personnel by sharing experiences. It can reduce training requirements, and there will be a significant reduction in the time of on-site repair and disable time .So it is very helpful to improve equipment readiness and reduce the costs of use and protection.

Build a remote diagnostic system based on Browser / Server Mode

B/S model includes three layers, the presentation layer, functional layers and data layers. The presentation layer is the user interface portion of the application which charged with the function of dialogue between the user and the applications. The functional layer is the body of the application which it compiles the specific business processing to one program logically. The data layer is a database management system, which it defines and manages the contact of the database and the application and it is responsible for the management of read and write data in the database. Accepting user requests through the network, executing corresponding processing, and then sending the response back to the browser, B/S mode further simplifies the client software. Because of the browser as a unified client, just modifying the server-side software, the system can be upgraded which it is helpful to system maintenance and management.

Remote fault diagnosis center should be built in research institutions, maintenance factories and office functions and connected with the troops through military communications network. The fault

diagnosis and maintenance of dynamic alliance which is composed of relevant experts who come from the institute, repair factories and manufacturing plants will provide remote troubleshooting and repair services for the system. All troops (client) establish a real-time fault detection system. When the local fault diagnosis system can not solved the problems, the troops can access the remote fault diagnosis center through military communications network. The remote system provides technical support, repairs the damaged equipment timely. So that technical resources can be effectively shared.

This remote fault diagnosis and maintenance system is divided into three layers. The first layer is the user diagnostic layer that it is “client” in the figure1. When equipment fails, fault is detected and diagnosed firstly by the fault diagnosis system resided in the user's own, and then the equipment is repaired. When they can not find out the reason, they apply for technical assistance to the center through military information network. That is the second layer-the center of the diagnostic layer. After the diagnostic center has received customers’ requests, it diagnoses and gives maintenance recommendations. The third layer is a group consultation.

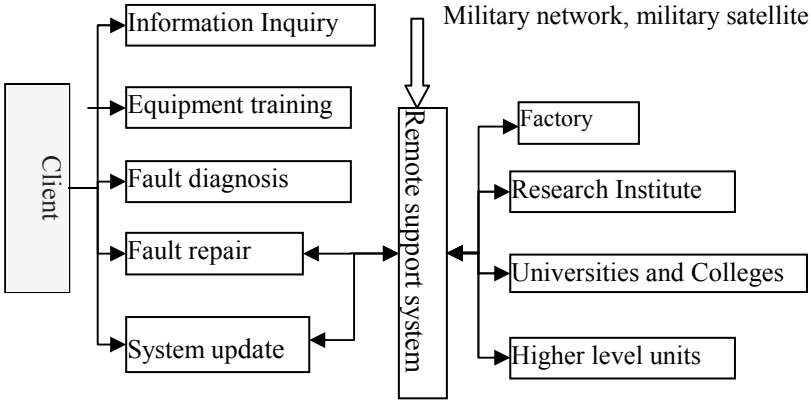

Fig1. The structure of the remote maintenance service

The remote fault diagnosis system has the following features: experts from all sides can achieve offsite "consultation" of many difficult problems through the network. The diagnostic knowledge and databases within the scope of the military will be shared and then it can provide reference and basis for solving similar problems of army. It also can achieve full life-cycle management of weaponry which is from the production, reserves to use and provide a reliable guarantee for improving equipment performance and combat effectiveness. With open system architecture, the new network’s forces can share all the resources online and it facilitates technology popularization and promotion.

Create Query System

VIRTOOLS production can get immersive virtual environment. It generates participants various sensory information such as vision, hearing, touch, taste, etc and gives participants an immersive feeling. So it is a new development, with the meaning of a new human-computer interaction system. The automata visual simulation of a certain type of equipment has achieved the maintenance of automatic systems in virtual conditions by the simulation of repair process of the systems. Visual simulation of the entire process with high fidelity can display the entire system all-round, and response real-time during operation with three-dimensional gesture.

Virtual Training

Users can take advantage of virtual operating platform and make equipment put into use as soon as possible with automatic machine virtual operating model which it is based on VC and VIRTOOLS using 3dmax modeling. At the same time, the model increases the virtual presentation capabilities by showing capabilities need to be operated by virtual reality or video mode. Among them, video presentation is strongly realistic so users can learn from the global. Virtual presentation has dual function of global and local and users can observe by cross-sectional and multi-angle.

Virtual Assembly

An important part of removable equipment maintenance is decomposition and combination of the equipment, but the complex structure always hampers the process of user operations. Virtual Assembly may well solve this problem. The key of virtual assembly is founding a reliable three-dimensional modeling of the new equipment. The specific technical route is: determining the serial number of the part by the order of assembly parts, curing the assembly sequence of equipment with the rules set by VC programming and judging that the parts of the assembly is qualified or not according the distance of separate parts and whole parts. In this process, whether the user's using dedicated tools is correct is judged by VC program, and the different perspective switch is completed by the use of the camera lens' conversion which it is convenient for locating the assembly quickly.

Virtual Maintenance

Virtual maintenance includes local and remote maintenance service. The local repair uses animation to reflect the failure phenomenon in VIRTOOLS and feedbacks to the user with the effect of auditory and visual. Animations mainly reproduce the fax machine's function of the original send and the copy, join judgment point in the phenomenon of simulation, and determine whether the object is faulty maintenance. If the object fails, the feature presentation will stop and present the symptom. Wave Player BB controls voice broadcast, Show BB and Hide BB real-time controls the display screen and warning lights texture, Cheek for Message BB is the failure to determine the point. Scripts of the symptom presentation can be written by the above combination of BB. The basis of fault diagnosis in virtual maintenance is judgment for collision. When users take virtual maintenance, there will be a collision, and the VC program will determine maintenance tasks and repair processes.

As new weapons being equipped, even if the troops have the virtual training system, they are still unable to combine virtual reality with actual equipment perfectly. Remote service just can complete this combination. This is reflected in the following two aspects: first, during the virtual maintenance training, users can interact with the remote expert through the system to seek remote support for solving difficult problems timely. Secondly, when users are maintaining new equipment, remote experts can guide the operation of the local virtual system to help local users directly by the platform.

Self-learning of the Fault Diagnosis System

Knowledge base Of new equipment maintenance system needs to update constantly by exchanges of manufacturers, research institutes and the users. Knowledge base of remote diagnosis expert system can be based on open architecture Web database. It consists of two systems: local knowledge and remote repository. Local knowledge is maintained by the users. With the operation and use of the system, the local knowledge will be enriched constantly. But, whether or not the samples of local repository are reliable lies on information exchange between users and remote experts. When remote repository receives the users' information, it is analyzed and summarized by full-time staff. And then it is updated and sent to all users knowledge base with the new version of the form. In this way, the user's response time of treatment failure is assured, but also the knowledge base has a wide coverage and a faster update rate. Diagnostic database established by the framework standard achieve a shared of diagnostic data formats and specifications. As long as the data comply with the standard, the system can identify. Thereby the open of the database is greatly enhanced. The management of system knowledge base is classified by failure characteristics of different devices. Each fault can be set or sets of solutions.

Information module based on fault diagnosis module. In fault diagnosis diagnostic database, history table has been created simultaneously. After the users inquiry fault diagnosis module, the "Symptom" of high frequency fault and maintenance difficulty coefficient, they can storage "Device Name", "Defective parts", "the best solution", etc. fields in history diagnostic library. In the next similar failure, having input "Access time", "Device Name", "Defective parts" selectively in Information module, users can get history record of the "best solution" directly which it is stored in maintenance program. Thus, it saves time that the client accesses to the server and improves the efficiency of the network.

Because access permissions of data maintenance module has high-level requirements for user roles, the system improves the encryption to this module in the application development process. The data maintenance module is used by a modular structure of B/S mode, and developed by the VC language. Only the client has installed data maintenance module subroutine and the users have been authenticated, they have permission to access the data maintenance module. It greatly improved the security of the system. In addition to managing the system users, data maintenance module mainly can extend the equipment of system remote technical support. As long as failure analysis of the device is made, fault tree model or troubleshooting hierarchical model is established, and equipment indicators such as introduction of equipment, technical parameters, methods of operation, maintenance guidance, are given, the model can expand the device to the remote diagnosis system maintenance database, and then it can expand maintenance equipment types of the system for remote diagnosis.

Summary

The remote maintenance system based on VIRTOOLS is mainly used in the field of equipment maintenance. It is a new maintenance program breaking the constraints of time and space. Network diagnosis and maintenance decision associate the design, manufacture, installation, use, maintenance and management organically by the data for the goal that the equipment runs safely and reliably. The system has accurate judgment in cause, nature, location of equipment failure and possible consequences, and it is significant for reducing the accident rate, shorting the maintenance time and improving the quality of maintenance. The network remote maintenance system based on VIRTOOLS will become the key technology during the army equipment management modernization.

Improved XFBT: A Low-power Topology of Network-on-Chip

Hongbing Chen[1, a], Chao Li[1,b]

[1]School of Computers, Guangdong University of Technology, 510006, China

[a]hongbchen@163.com, [b]771781910@qq.com

Keywords: NoC; topology; low-power; improved XFBT

Abstract. The article discusses the issues related to the on-chip network topology, analyzes the XBFT topology, improves its structure in power consumption. Authors designed a simulation program that by analyzing the topology routing hops to roughly determine the power consumption of routing topology and for the preparation of modified XBFT roughly determine the topology of the routing topology by analyzing the power consumption topology routing hops the simulation program, Finally, the results from the running of 6 simulation program that extracted and these results were analyzed. The result shows that the improved topology saved about 20% of the number of routing hops.

Introduction

According to Moore's Law , integrated circuit performance approximately doubled every 18 months . Before SoC, Integrated circuits primarily by increasing the number of transistors that Integrated circuits accommodated to achieve improved performance, but with the IC into the ultra-deep submicron technology and IP core reuse dominated era , doubling the number of transistors again in a certain area on the chip has become very difficult, doubling the number of transistors again in a certain area on the chip has become difficult, the limited address space bus architecture, time communication, global synchronization caused by poor scalability, low communication efficiency, high power consumption and other issues severely limits the MPSoC development.

To solve the problems facing the development of complex MPSoC , learn computer network communications-centric thinking, presents a number of research institutions MPSoC Solutions - From the architecture to solve the communication bottleneck of MPSoC, Use this method to Solve problems of bus architectures.Compared with the bus architecture MPSoC, on-chip network (NOC) has good scalability, reusability, flexibility and parallelism [1-3] and so on.

NoC mainly concern is the problem of communication between multiple processing units, in the chip design process, bisection width and other aspects select the appropriate topology is one of the important research focus NoC. MPSoC development , especially the wide application of mobile intelligent terminals , power endurance of systemsis one of the main measure of performance parameters , prompting chip design increasingly take into account the power factor , low power consumption -oriented topology designed to be hot chip design research questions .

NOC topology description

NOC topology can be described using graph theory . In the on-chip network ,topology can be expressed as a mathematical model linkages between the IP core collection and a collection of discrete IP cores in concrete , which is defined as described in Definition 2.1 .

Definition 2.1 A network topology (Topology) is an ordered pair <N,L>, denoted by T = <N,L>, where:

N = {n1, n2, ..., nn} is a finite non- empty set , ni called nodes (node), N is called the set of nodes (node set).

L is a finite set , called the link set (link set). Each element in the L N in the corresponding node , called a link .

Each nodes exchange information through links,such a figure is a communication network. NOC topology directly affect the routing of IP core network node and the network map and

determine the diameter of the network chip , Thus the chip average network latency, area, network throughput, power consumption and other performance parameters plays a critical influence the NOC topology features fully reflected in the topology itself parameters. From graph theory and computer network -related knowledge, the mainly parameters of the topology of the nodes , the network diameter , the width of the points of the sub- bandwidth connectivity and so on.

Common NOC topology

NoC topology divided into regular and irregular types. Topology rules with the rules of network parameters, has good reusability, scalability and versatility, and simple. Regular topology can be divided into direct network and indirect network according to whether each communicate node of network has computing nodes directly connected, Unlike regular topology as regularity, Irregular network topology parameters mostly are based upon the specific application customization or combination other characteristics,can be optimized in in power, latency, area, and throughput, etc.Currently, a common NoC topologies are mainly 2D Mesh[4], 2D Torus[5], Octagon[6], Spidergon, CLOS, SPIN and so on. Some common NoC topology is shown in Figure 1.

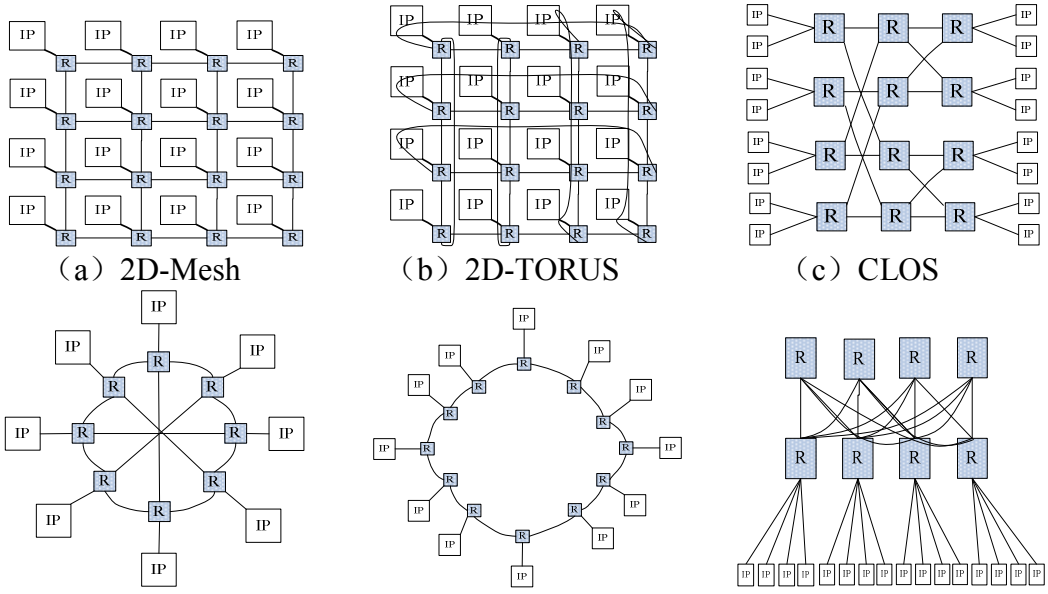

Figure 1 Some topology of NoC

Improved XBFT topology

XBFT topology is described by Zhou liberal arts degree thesis in his study of network topology and routing algorithm on an improved type of film BFT proposed [7] . Figure 2 is a schematic XBFT 64 when this topology calculating means to the IP core. Can be seen from the figure , routing hops required for its communication procedure up to 6. Each computing node 4 is connected to a routing node , and only connected to the routing node on the first layer. The first layer is connected to the routing node twenty-two form a link pair, then the routing node and the second layer connections . Each routing node of the second layer and the following pair of two adjacent links , respectively, to select and connect the two routing node , the network component 16 comprises a computing node , which is required for the communication process through the hops The maximum number is 3. In other words, XBFT tree almost from the beginning than the information routing hops torus structure is less that XBFT tree topology to be less than the power consumption torus structure. Each sub-network in the same layer as the second layer next to the routing node connected between the additional connection to a node is the less.

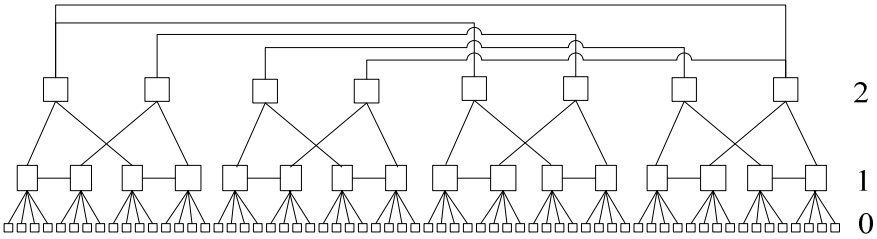

Figure 2 XFBT topology

XBFT structure of an improved structure shown in Figure 3, the base structure of high XBFT improved to some extent on the path router, the number of nodes such that each routing node can be connected to a relatively large saving on the cost of the mountain road the integrated circuit device. At the same time, Unlike regular topology as regularity, Irregular network topology parameters mostly are based upon the specific application customization or combination and modifications of topology rules, has specificity and efficiency and other characteristics,can be optimized in in power, latency, area, and throughput, etc. In connectivity, improved XBFT structure let the first layer routing node sequentially divided into four groups, each group has four routing nodes; The second layer routing node is according to their order of appearance in the second layer routing node to link position corresponding routing node of lower routing group A connector as in each group of the first router, B is connected in each group of the second router. Through this connection, you can reduce routing hops message in the communication process through which that reduce the distance between the two compute nodes, while increasing the connectivity of the network.

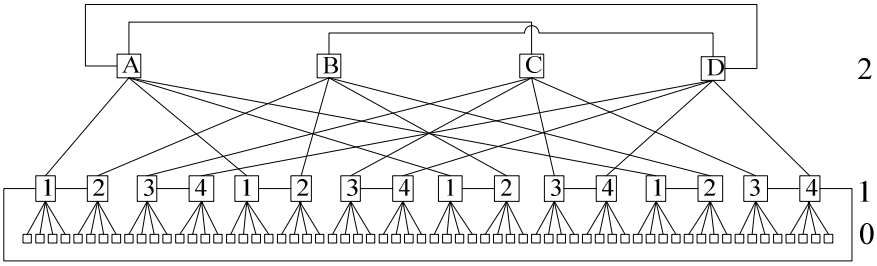

Figure 3 Improved XFBT topology

The simulation results and Summary

This article uses the C language simulation program on REHLL5. The simulation program to simulate the topology of the communication process to measure performance and power topology, you can configure the router and the power consumption of each link must be used to determine the shortest path routing communication process data transmission path, the simulation only consider routing hops, the main consideration by reducing the number of router hops to measure power performance. So by getting any two nodes in the route calculation the average number of hops, to compare the power consumption of the two topologies are feasible and more intuitive.

This made a total of six groups of six test data obtained, respectively, the input number of communications computing node 100 times, 500 times and 1000 times. As shown in Table 1, improved topology routing hops are significantly reduced.

Table 1 Router routing hop number

	XBFT topology routing hops	Improved XBFT topology routing hops
6400	26875	19984
32000	131604	103814
64000	263112	208915

As shown in Table 2, the average number hops of improved topology roughly about 25 percent to 80 percent for the improved topology.

Table 2 Router average routing hop number

	XBFT topology average routing hops	Improved XBFT topology average routing hops
6400	4.20	3.12
32000	4.13	3.24
64000	4.11	3.26

Combined with the above data analysis, improved power consumption without considering the topology of the crossbar and distribution circuits and connections, such as specific logic circuits and routing algorithms and topology-independent factor F. Improved power topology is not improved 80 percent of the mountain road topology XBFT.

Keywords: Grid; Mutation; Service; Optimization

Abstract. Database grid service provides users with a unified interface to access to distributed heterogeneous databases resources. To overcome the weakness of collaborative services ability in different grid portal, a new grid portal architecture based on CSGPA (Collaborative Services Grid Portal Architecture), is proposed. This paper aims to enhance the performance of PSO in complex optimization problems and proposes an improved PSO variant by incorporating a novel mutation operator. Experimental studies on some well-known benchmark problems show that our approach achieves promising results.

Introduction

PSO is a recently proposed intelligent search technique, which was inspired by the social and cognitive behavior of swarm. As mentioned before, PSO as well as EAs are population-based random search algorithms, which usually start from a set of initial members or particles (called initial population) and towards the global optimum by executing iterative operations. In PSO, each particle has two features: velocity and position. The velocity determines the step size of movement every generation, and the position represents a candidate solution in the search space. Every generation, PSO utilizes a velocity and a position updating equation to recalculate the new velocity and position of each particle. When a particle moves in the search space, it remembers its previous best position (called pbest) and the global best position (called gbest) found so far. PSO's social and cognitive behavior is based on these two particular particles. The grid is a giant supercomputer of high efficiency, which integrates the distribution system and heterogeneous computing resources, and it provide the full sharing of computing resources, storage resources, data resources, information resources, knowledge resources, expert resources, and equipment resources [1]. Grid Service is the use of grid services for users. In this paper, GDT is used to establish the database grid service for handling and processing the distributed, heterogeneous database.

In the grid environment of grid system architecture based on OGSA, each grid resource is seemed as a grid service. These grid services are provided to grid users to sharing use [2]. Grid portal is to provide a way of users accessing the grid resources, and each single grid portal can provide a subset that users can access these grid resources, therefore, grid users need to access different grid resources via independent and different grid portal, and the situation of the current existing grid portal is also like this. How can we make the single grid portal connect better, make the different grid portal collaborate services for users needs. The paper puts forward a new grid portal, which can make the single grid portal share the information, share the grid resources and a strong scalability system architecture to build new grid portal. We named Collaborative Services Grid Portal. Because of the formulation of the WSRP (Web Services for Remote Port lets) standard, making use of WSRP, users can standardize the single grid portal architecture of all the organization [3]. In the portal architecture, many small portal share the content, and needn't deploy the single portal any more, each IT service only deploy once, and then it can achieve to use all IT service consistently. Therefore, WSRP provides the strong support for collaborative services grid portal [4].

At present, data of each application fields is increasing at an amazing speed. In the real application environment, most of massive databases exist in the form of distribution. If the distributed data was concentrated into a data warehouse for mining deal, it will pose a threat to the distributed data's security and privacy, and further reduce the efficiency of mining, but also make a

higher requirement of network communication bandwidth. It becomes an urgent requirement to achieve sharing among the distributed and heterogeneous database resources.

Database grid service can support high-performance needs and data distribution well, and store, manage huge amounts of data more effectively, and analysis and handle a large number of heterogeneous distributed database resources more efficiently. Database grid service has many applications features, such as data-intensive, data resource diversity and heterogeneity, large-scale collaboration with the local control rather than global control, data security, load balancing of data resource access, etc. Clients interact through the appropriate database grid services and data service resources. The database grid encapsulates the function that need to use Web Service interface to open data services resources.

Database Grid Service Introduction

According to practical requirements on site, the online computer five-anti system based on multi-layer network architecture is designed with the help of current advanced communication technology and embedded technology. The system architecture is shown as Fig.1. The intelligent lock is the important components of online computer five-anti system. Different electrical equipments have their special requirements for lock method due to their different structures and operation principles. So different latch locks should be installed based on site conditions.

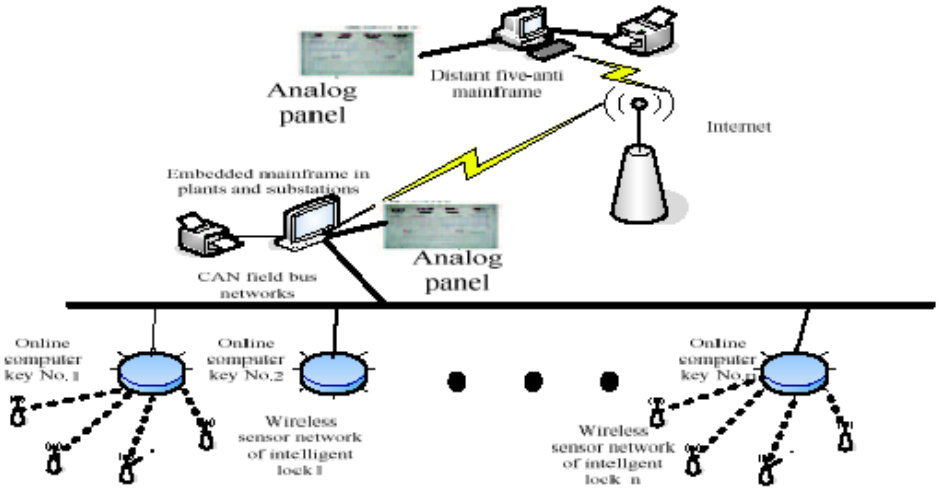

Fig.1 System framework based on multi-layer network architecture

Architecture and Operating Mechanism of Collaborative Services Grid Portal

The architecture of collaborative services grid portal is shown in Fig.2. Its operating mechanism is as follows.

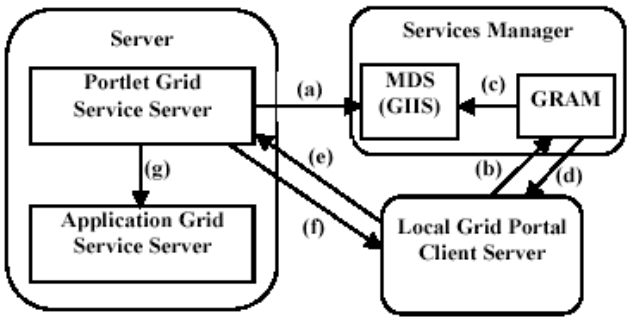

Fig.2 Architecture of CSGP

Hardware Circuit Design

The Central Processing Unit (CPU) applies the industrial chips of MC9S08 AC16, which are industrial eight-digit single-chip microprocessors with ultra-low power consumption. This type of chips internally integrate a 16K-byte FLASH and a1k-byte RAM memory with SPI interface, A/D conversion circuit.

CC2430 has small number of external components. It employs an unbalanced antenna to connect the unbalanced transformer so as to make the antenna have better function.

The parts of hardware in detail are designed as Fig.3.

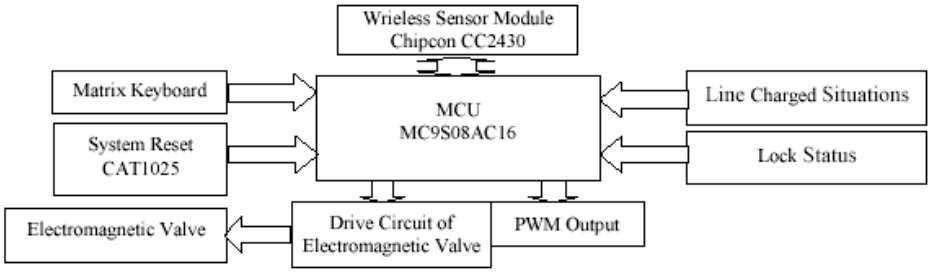

Fig.3 Hardware system framework

In the collaborative services grid portal architecture, a server can allow running many Port let grid services, and of course, the whole architecture also allow existing many Port let grid services which provide the same function, some Port let grid service can access the corresponding one or more application grid service. By this means, Port let grid service can mainly process the display logical. Port let grid service provide an interface service to the terminal users of the grid portal, while the gird resource that terminal users need to access and use, is provided by the application grid service running on the other server. In this way, we can separate the display logic from the application logic in grid portal better. In the whole grid portal system based on collaborative services grid portal architecture, the amount of the servers of running Port let grid service can be dynamic change, but they don't have the close connection between the each Port let grid service server, so any one server goes wrong, it will not influence the normal operation of the whole architecture. To the requestors, because of each Port let grid service is developed based on the standard, so the requestors are very convenient to plug Port let grid service in grid portal itself by configuration, and don't need to add other program code.

In allusion to the network topology and application distribution of grid system, combining with the collaborative services grid portal architecture above, we provide the application system architecture based on CSGPA, as shown in Fig.4.

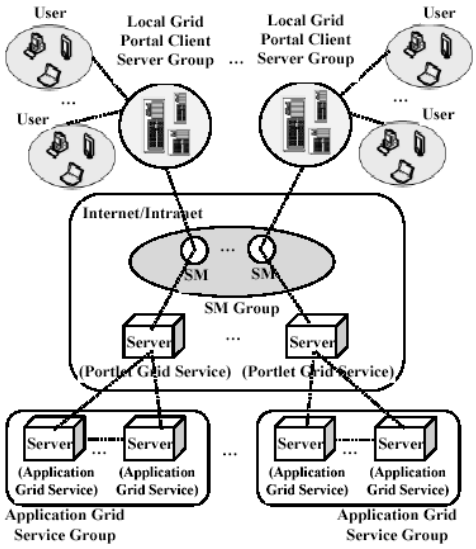

Fig.4 Application system architecture based on CSGPA

Conclusion

It is to hope this improvement can help trapped particles jump to better positions. Simulation results on ten problems show that CSGPA not only achieves more accurate solutions than PSO, but also converges faster. Collaborative services grid portal architecture is presented in this paper. Through our study, analyze and evaluation contrast to the architecture, we can find that the architecture is clearer than some current grid portal architectures, and it improves the scalability and reusability of the grid portal. The emphases of next step work are to solve the dispatching problem in the case of the large number of concurrent and the many-to-many relationships problem of grid service.

Keywords: Capacity Utilization; Improving; Failure Detection; Algorithm

Abstract. There are many factors that can affect network performance, such as delay, packet loss and capacity utilization. A Wireless-Optical Broadband Access Network (WOBAN) is gaining more attention because its good performance and merits such as reliability, robustness and high capacity as well as flexibility. In this paper, we proposed the Flow Limited and Risk Aware Routing Algorithm (FLRAR), which takes capacity utilization and link failure into account. And we also used Link Success Rate (LSR) to detect the link failure and redirect the related packets. The research results show that the process of information fusion has abilities of adapting and self-learning.

Introduction

A Wireless-Optical Broadband Access Network (WOBAN) is a hybrid of wireless networks and optical networks with passive optical networks (PON) in its backend and wireless mesh networks (WMN) to supply end users with the access[1]. The head terminal of PON resides at Central Office (CO) which is driven by Optical Line Terminal (OLT), while the tail end consists of Optical Network Units (ONU). ONUs connects to wireless Base Stations (BS) which form a multi-hop wireless mesh networks. Some BSs are called gateway routers, of which the location is critical. The end user sends packets or messages to one of neighborhood BS (or called routers). This BS then sends the packet into wireless mesh of WOBAN. The packet will reach the optical backbone through OLT/OC in the manner of multiple hops. The upstream of WOBAN in the wireless end is any cast while the downstream of WOBAN in the wireless end is uncast. This architecture can heal and organize itself with help of wireless mesh networks. The architecture is shown as Fig.1[2].

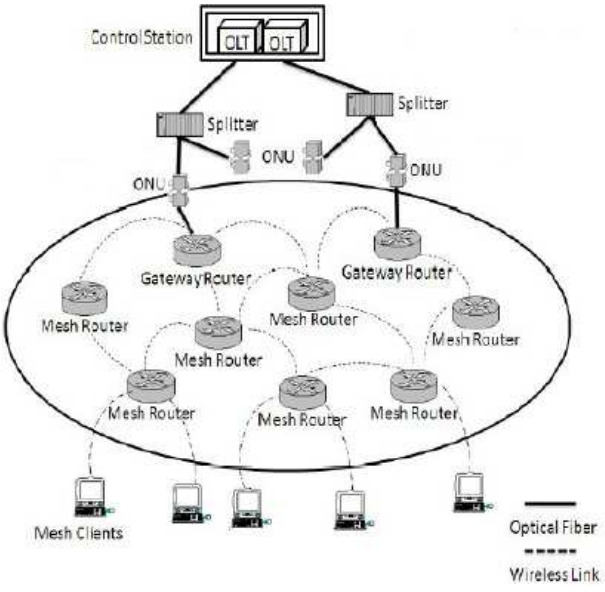

Fig.1 Architecture of WOBAN network

Performance Analysis

In this part, we will discuss the network performance based on FLRAR in four parts: load balance, number of hops, bandwidth utilization and self healing.

A. Load balance

If we only consider one aspect of the network constraints, other aspects of the network performance pay affect the whole performance. Take delay for example. If delay is the only factors for the algorithm, proposed in [3], congestion will occur if most packets select one single link whose link weight is minimum for transfer. We call this load congestion. In our algorithm, we set the link capacity and LSR for each link, which ensures that the load on one link cannot cause the load congestion and also ensures that the network can detect the link failure on time. So FLRAR helps to achieve the load balancing in the network[4]. We show this in Fig.2.

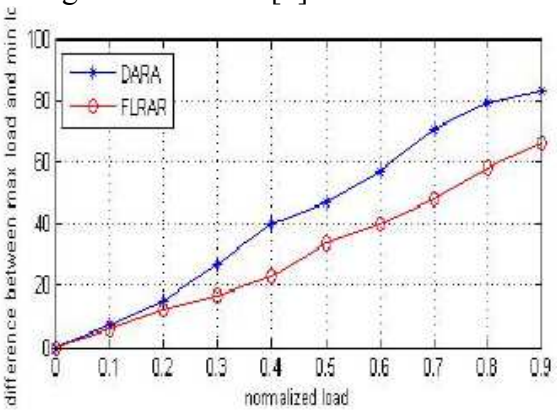

Fig.2 Comparison for load balance

B. Number of hops

Although the algorithms such as SPRA and DARA can effectively reduce the hops of the data link, lack of considering capacity and link failure cause the whole hop number increases as the load in the network increases. Our algorithm, FLRAR, effectively take capacity and link failure into account, which means that the hops will decline to an ideal level.

C. Bandwidth utilization

According to the previously proposed algorithms, such as DARA, the link with minimum weight will be assigned much more lead than other links. This will cause the bandwidth of this link is over utilized, which will cause congestion in the network. While other link bandwidths are underutilized. In FLRAR, the load is dynamically allocated according to the link condition. Thus FLRAR can increase the bandwidth utilization.

D. Self healing

In our algorithm, if one link gets failure, the LSR will decrease and the LWA will increase, which will cause tags added to the packet in this link. As a result, the network will redirect the packet to backup links. So FLRAR can achieve self healing effectively. To sum up, FLRAR can optimize the network performance in load balance, number of hops, bandwidth utilization and self healing.

Simulation Model

From the performance analysis, we can find that FLRAR can significantly improve the network performance in load balancing, number of hops, bandwidth utilization and self healing[5][6]. In this section, we choose bandwidth utilization and packet loss to simulate the model. The simulation model generates 1500 data packets and the repeating time is 10 times. For the bandwidth utilization, we compare the FLRAR and DARA; for packet loss, we compare FLRAR and CaDAR.

Fig.3 shows the capacity utilization of FLRAR and DARA. We can find that DARA maintain the capacity utilization at 50 percent as it select the data link only based on the LWA. On the other hand, with the increase of the load, FLRAR gain more and more advantage on capacity utilization. When the curve becomes flattened, the value can reach 70 percent. This shows that FLRAR have

advantage on capacity utilization. If we take one step further, we can get that FLRAR is suit for the extension of the network, as the load increases, the data link can be allocated dynamically, thus reduce the congestion.

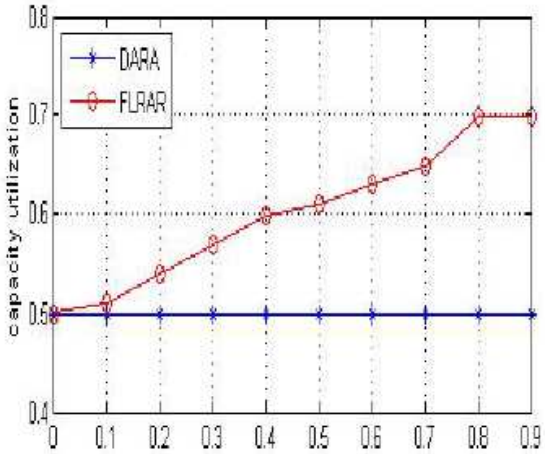

Fig.3 Capacity utilization of FLRAR and DARA

Fig.4 shows the comparison of packet loss number of FLRAR and CaDAR. The result shows that the tendency of two algorithms is the same. However, FLRAR can effectively reduce the packet loss number in order not to reach the threshold. On the other hand, CaDAR may cause too many packet loss, thus LSR is less than the threshold. The result is uniform with the performance analysis. So we can get that FLRAR can effectively reduce the packet loss.

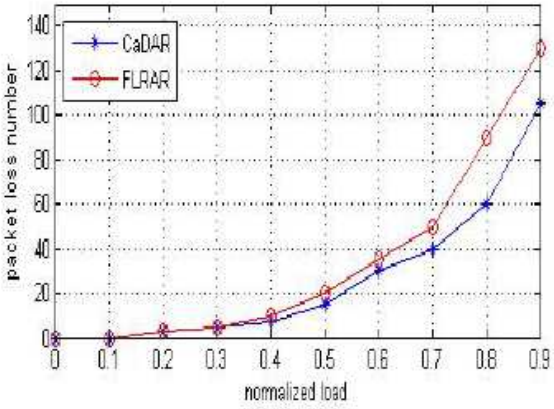

Fig.4 Packet loss of FLRAR and CaDAR

Conclusion

WOBAN is an effective architecture as it combines the merit of both wired and wireless network: reliability, robustness and high capacity as well as flexibility. However, ineffective routing algorithm can cause the declination of the network performance.

Flow Limited and Risk Aware Routing (FLRAR) algorithm take many factors into account, such as flow in each data link and link failure. It improves the network performance in load balance, number of hops, bandwidth utilization and self healing. The advantage of FLRAR is significant when the network load increases, so it is good to improve the scalability of the network.

Keywords: Algorithm; Image; Fuzzy NN; Expert System

Abstract. Because the traditional linear vectorization methods have some shortcomings including processing data slowly, being sensitive to noises and being easy to be distorted. Fuzzy rules and its inference mechanism are the assurance of achieving feature fusion. However, the self-learning function of FNN could train its weights; it is difficult to optimize fuzzy rules. Besides, the common FNN training algorithms have low constringency speed and are liable to run into the local optimization.PSO algorithm has high convergence speed and it is simpler on the operation and is more potential on optimizing FNN. Thus, PSO algorithm could be adapted to train FNN weights, and prune the redundancy links, optimize fuzzy rules base. In the paper we present an improving immune genetic algorithm based on chaos theory. The over-spread character and randomness of chaos can be used to initialize population and improve the searching speed, and the initial value sensitivity of chaos can be used to enlarge the searching space. To avoid the local optimization, the algorithm renews population and enhances the diversity of population by using density calculation of immune theory and adjusting new chaos sequence.

Introduction

Genetic algorithm (GA) is an effective probability searching algorithm based on the natural selection and the genetics principle, and it carries on the search and the optimization through the simulation organic evolution, and it automatically gains and accumulates the related knowledge of searching space in the searching process, and it controls the searching process to obtain the optimal solution of the question.

The genetic algorithm has many merits such as the good overall search ability and easy realization and so on, but it also has some insufficiencies such as the slow convergence speed and the bad partial searching ability and easy precocious and so on, and it cannot obtain the unsatisfied solution frequently when it solves the optimal question of continuously differentiable complex multi-peak function. The expanded population scale and the improvable heredity operator can improve the partial searching ability, but it can reduce the operating efficiency of algorithm too. The immunity evolution algorithm is an emerging algorithm which develops by the immunity concept and theory in the life sciences[1][2]. This algorithm has many characteristics such as automatic identification of antigen, feature extraction, the diversity of immune body, distributional examination, learn and memory, self-plan etc, and it is also parallel distributional self-adaptive system which has the great potential in the application of intelligent computation. In recent years the immunity genetic algorithm has obtained the widespread application in many domains because it can effectively maintain the diversity of population and eliminate not mature astringency and the oscillatory occurrences. The reference presented an immunity genetic algorithm which extracts vaccine from the system knowledge and vaccinates to the evolution process, thus, it can fully use the system message, but the algorithm has not considered the diversity of population which influences the evolution process.

Feature-Level Fusion of Detection Information Based on Fuzzy Neural Network and Expert System

The feature-level fusion algorithm could be proposed by integrating FNN and ES. The fuzzy rules and its inference mechanism are the assurance of achieving feature fusion. However, the self-learning function of FNN could train its weights; it is difficult to optimize fuzzy rules. Besides, the common FNN training algorithms have low constringency speed and are liable to run into the local optimization.PSO algorithm has high convergence speed and it is simpler on the operation and is more potential on optimizing FNN. Thus, PSO algorithm could be adapted to train FNN weights, and prune the redundancy links, optimize fuzzy rules base.

The structure of fuzzy neural network is shown as Fig.1.

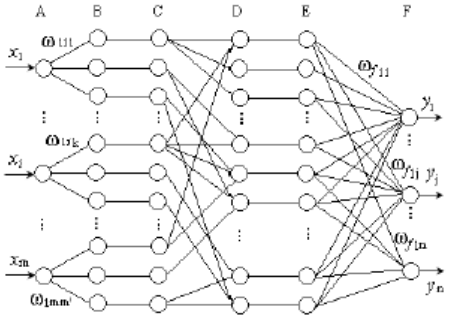

Fig.1 Structure of fuzzy neural network

For ease of comparison and visualization, the discriminator gains were normalized. The discriminating performance curves of the three algorithms with the correlator placing d = 0.25 (chip) and d = 0.5 (chip) are presented respectively in Fig.2.

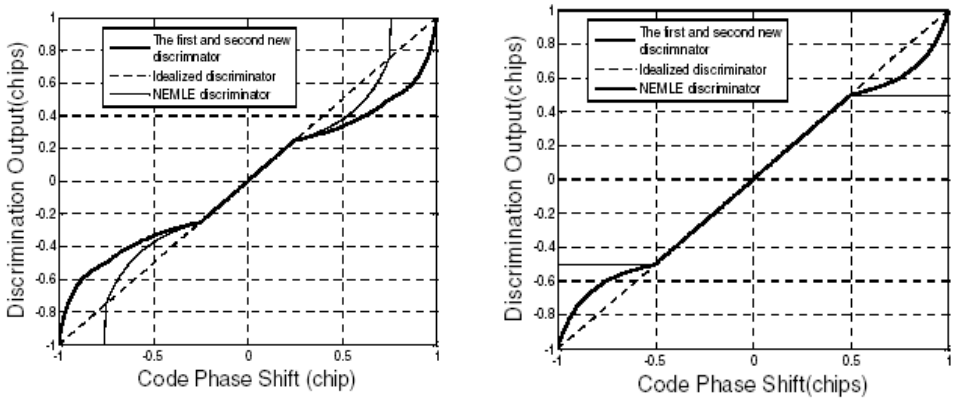

Fig.2 Discriminating performance curves with the correlator placing *d=0.25*(*chip*) and *d=0.5*(*chip*)

The analysis of the comparison obtained from Fig.2 is that, discriminator is better when d=0.25(chip), and the two new discriminators are better when d=0.5(chip).

Basic Theory in Mathematic Morphology

With the extensive application of digital images, vectorization of the original paper images has become an important task [3]. There are some shortcomings in the traditional method used in the image vectorization, such as the slower processing rate, sensitive to noises and easy to be distorted. Mathematical morphology, a nonlinear methodology, describes the characteristic of each image researched and the relationship between them by studying the geometry characteristic of objects in the image researched [4].

The mathematical morphology of binary images is the most basic morphological theory. The so-called binary image is the image whose gray value is either "0" or "1". Applying the basic binary morphology operations and combinations of them, we can analyze and process the shape and structure of the image. Supposing A is the original image to be processed (also called the target point set) and B (coordinates (I, J)) is a structural element, we introduce these types of binary morphological operations.

The original scanning image and the linear feature extraction results of the scanning images attained by this method are shown in Fig.3.

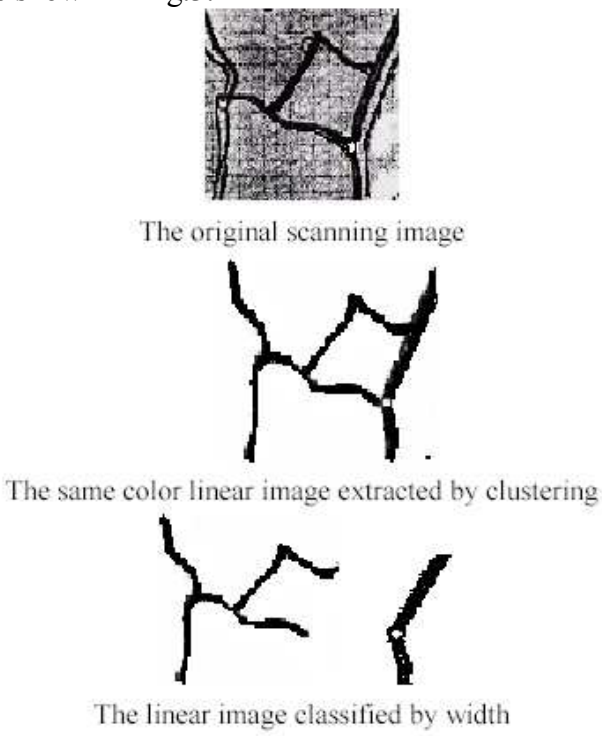

Fig.3 Results of edge detection algorithm based on the four structural elements

The noises and edges in the image are the places of the mutation of gradient, but the edge has different form from the noise. So during the edge detecting, we should confirm the pixels firstly and then distinguish the pixels to confirm they are the edge or the noise according to several structural elements. Filter them out if they are noise, otherwise retain them. Because we needn't take a mathematical morphology operation for each pixel of the image, large numbers of unnecessary operations are reduced. This operation can be carried out as following three steps:

(a) Select pixels of the mutation of gradient by taking use of the difference of adjacent pixels;

(b) Take the several structural elements binary morphology erosion operation for pixels of the mutation of gradient, so that we can filter out the noise and extract the edges;

(c) Attain the edge image.

Experimental Analysis of Performance of Two New Algorithms in Tracking Loop

The digital IF signal data with the sampling frequency 8.184MHz and the fixed Doppler frequency shift -600Hz, is generated by using simulation method. Supposed that, after signal acquisition, the carrier Doppler frequency estimation value is 590Hz, and the code phase estimation values are respectively 199.5(chip) and 199.2(chip). In the carrier tracking loop the sentenced cross-type FLL discriminator was used, and the correlator placing d is set to be 0.5(chip). Under these conditions, the signal tracking process can be presented respectively by Fig.4.

This algorithm combines the genetic algorithm, the immune algorithm and the chaos theory, it regards the question as the antigen, and it regards the solution of the question as the immune body. The affinity through the antigen and the immune body describes the approachable degree of the feasible solution and the optimal solution. To the outside antigen's invasion, the system produces the immune body through the chaos, and the system realizes to environment auto-adapted through the immune body density's judgment and adjustment. To enhance the precision of the solution and improve the convergent speed, the chaos is used to carry on the partial optimization nearby the optimal solution. The immune body density calculation is one of essential methods which retain the diversity of population.

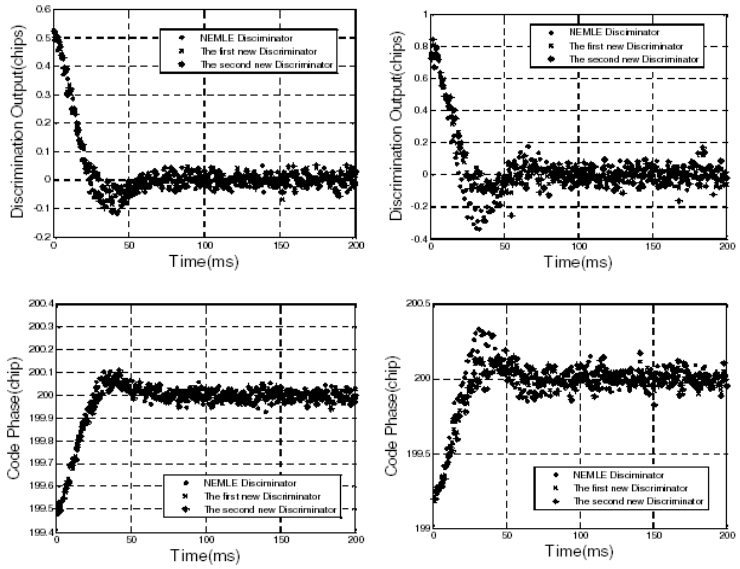

Fig.4 Tracking performance with the code phase estimation 199.2(chip) and 199.5(chip).

Conclusion

PSO algorithm could be adapted to train FNN weights, and prune the redundancy links, optimize fuzzy rules base. In the paper we present an improving immune genetic algorithm based on chaos theory. The over-spread character and randomness of chaos can be used to initialize population and improve the searching speed, and the initial value sensitivity of chaos can be used to enlarge the searching space. The algorithm applies in the function optimization question. The improved algorithm brings the question space and the corresponding solution space into correspondence with the antigen and the immune body, and it controls the reproduction of the partial optimal solution through the density. The algorithm can improve the search speed because chaos is introduced in the initial population and diversity adjustment. The algorithm can carry on the local optimization and increase precision nearby the optimal solution. The result of experiment shows the algorithm validity. We can draw a conclusion from experiment comparison, the paper's algorithm makes average movement algebra small, and the algorithm overcomes the shortcoming of slow convergent speed which generic algorithm has, and the algorithm is superior to convergent speed of immune genetic algorithm. Through the optimal value, we come to the conclusion that the paper's algorithm can avoid the local optimization and overcome precocious phenomenon of the genetic algorithm. Through the average optimum value, we may see the paper's algorithm has the good stability.

Keywords: Social Engineering; Network Security; Complex Network; Deception

Abstract. The social engineering techniques such as flattery, persuade, induce, disguise, threat, obedience and infiltration was summarized. The main methods and steps of social engineering research and the main six aspects contents such as social engineering technology analysis, social engineering case survey were also put forward. Finally, a model of social engineering attack based on complex network is built and some prevention methods aiming to social engineering attack were presented.

Introduction

Vulnerability of network security is ubiquitous and any system has potential security risk. As taking more advanced and rigorous system security protection measures, exploits are becoming more and more difficult in technology [1]. Considering higher cost of attack and big technical difficulty, network attacker has to seek human vulnerability, which is called social engineering. The incident breaking through network security protection with social engineering method presents the obviously up-trend in recent years and it has been the most vulnerable link. It will be an important network security countermeasure field of information invasion in future.

Summary of Social Engineering

Social engineering originally means studying social problems with engineering method. In network security, it especially means the skillful use of some peculiarities in human nature including curiosity, greedy, trust, obedience and instinct by attacker for stealing valuable information. It combined multiple subject knowledge and skills including psychology, human relations, praxiology and so on [2]. Such attack involves every aspect and they influence one another and it has been seen as a very complicated systematic engineering. So this attack method is named by social engineering.

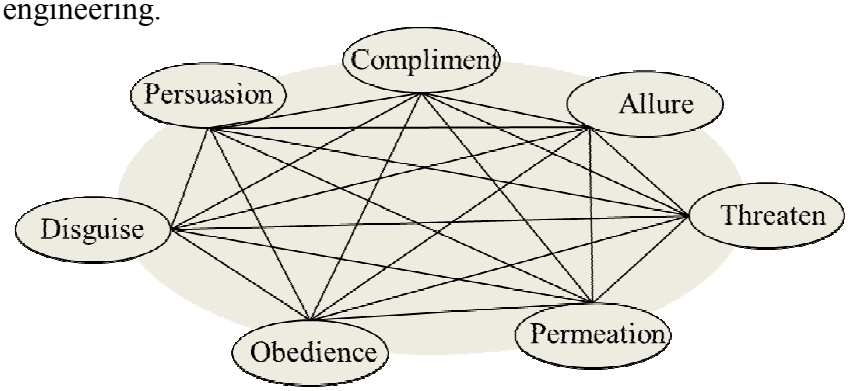

Fig.1. The relationship of multiple social engineering attack means

Differences between social engineering and other attack method are combined application of psychical attack and behavioral attack. As it is shown in Figure 1, the psychical attack was given even more weight and main means covers compliment, persuasion, allure, disguise, threaten, obedience, permeation, and so on. A wise network attacker of social engineering will never dwell on single means during the process of attack and they will be instinctive to perform attacking with one or more methods based on practical situation. They can easily jump from one method to anthoer method and make attack impossible to protect.

Research Precedure and Method of Social Engineering

Socail engineering can be reserarched as follow steps. Firstly, main components of social engineering method will be extracted to perform mental analyzing and technology analyzing according to investigation statistics. Secondly, the whole process of attack should be abstraction modeled and be described with XML format, which can provide model driven for subsequent simulation [3]. Thirdly, all attack means of social engineering is reproduced in order to provide research objects and samples protecting network attack of social engineering. Finally, traceback aiming at attacker will be performed to help analyzing mental activity locus and behavior pattern. The research precedure is shown as Figure 2.

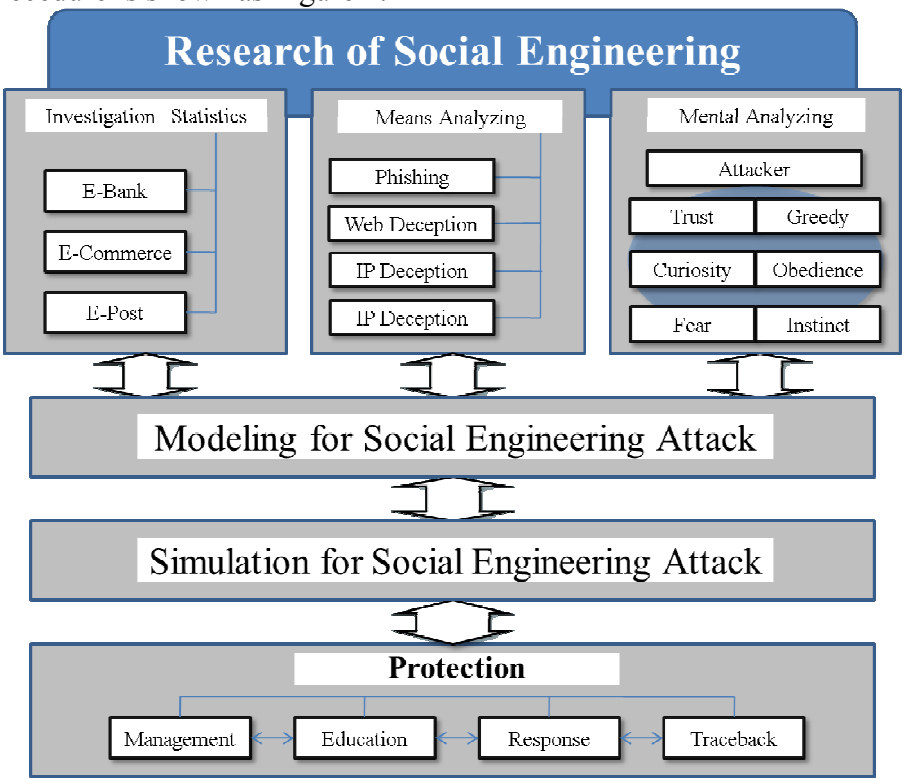

Fig.2. The research precedure of social engineering

Research methods are mainly consistes of five different kinds. First is comparing with various technology methods of social engineering. Second is investigating to massive network user extensively. Third is analyzing to mental activity and attack process, which will finds its features and laws. Fourth is building mathematical modeling for social engineering attack. Fifth is simulating attack means and performing actual attack with special respondents.

Studies of Social Engineering

Case Study. Social engineering attacks aiming at E-bank, E-commerce, etc will be investigated as a case sample. Cases can be collected by discussion and questionnaire with numerous sample workers. So first-hand materials and samples will be gained by analyzing with attack results in investigation case.

Means Analysis. All kinds of attack means including network phishing, Web deception, IP deception, DNS deception must be analyzed. Social engineering attacks mianly directs at mind habit and mind set, its behaviour rules and feartures are traceable. There is association between technology and attack tool. Rules can be summarized by analyzing process, method and means.

Mental Analysis. It analyzes mental of attackers and objects. Both attack object and protection object are persons, whose network behaviours are easily influenced in mental including greedy, fear, trust, curiousity, obedience, instict, etc. Aiming at different targets, attacker can apply comprehensive with multiple means. So it can help protect network attack by reproduced thought processes of attackers.

Attack Model. A complete social engineering model should be built with case study, means analysis and mental analysis. It covers most of the aattack methods and means. Attack and protection can be studied mathematically, and probabilities of success can also be calculated in allusion to each attack.

Simulation. That is simulation for social engineering scene and attack. Real experience will be provided to investigation object in simulation and it can also protection awareness aginst social engineering attack.

Protection. It is not only passive protection for social engineering attack. Besiding security management, educaiton and emergency response, it can find out physical adress and IP adress of attacker by traceing source and back. So attackers will be investigated and revenged even they successed.

Attack Model

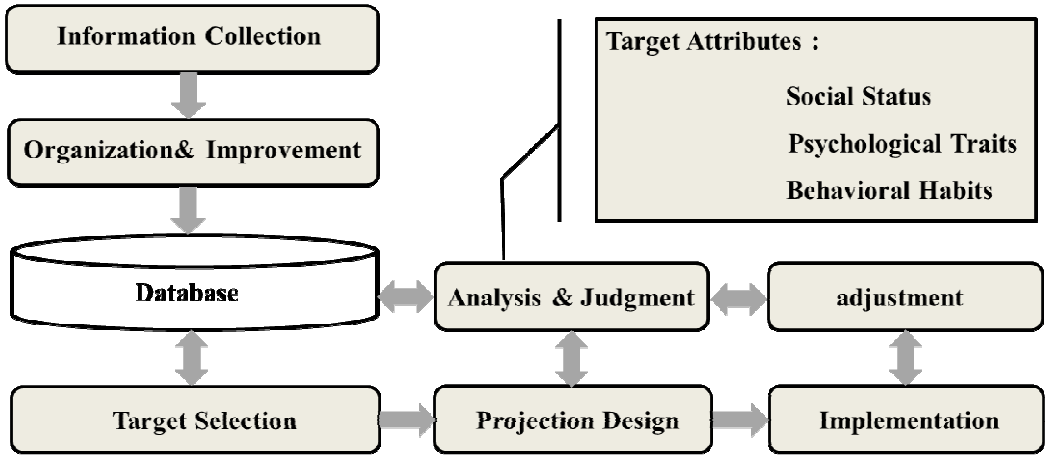

Fig.3. The model of social engineering attack

Social engineering attacker usually collects all kinds of information preparing for subsequent attack action. As it is shown in Figure 3, analysis and judgment will be the most difficult and complicated steps in social engineering attack model together with projection design. Human being is the world's most complex organisms owning nature and social attributes. Social engineering attackers can't success even they have further studied sociology, psychology, human relations, praxiology, economics, politics, and so on. Basing on viewpoint of complex network, relationship of creatures in nature and social life forms a very complex network [4]. It is shown in Figure 4.

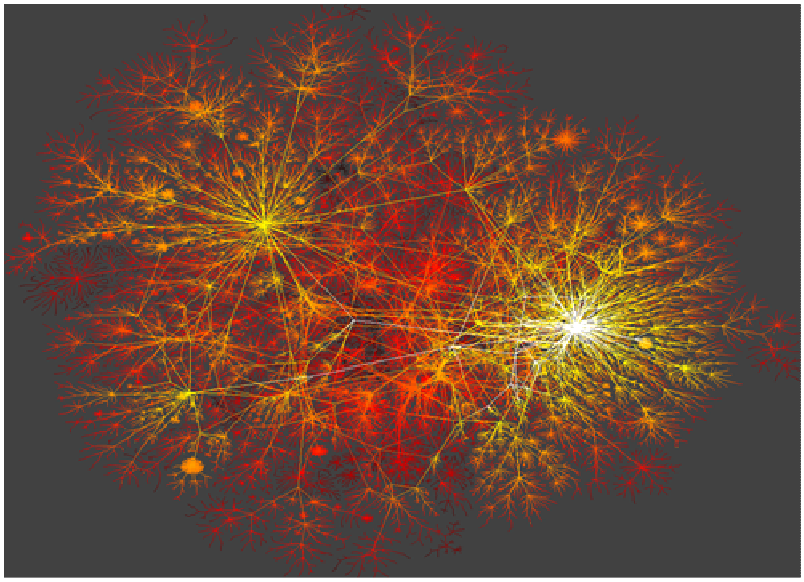

Fig4. The complex network of relationship

Security Protection

Social engineering attack isn't simple deception and it involves complicated psychology elements. It is hard to protect user from attack for it is difference to attack with technology methods [5]. It is critical that two operations including checking identity and authorization of requester must be acted. In general, protection can be started with security awareness, educational training, security management, strategy making, security technology, and so on.

Correct Security Awareness. Protecting personal information should be paid more attention and learned. Security concept must be clutivated to enhance protection awareness and form rational analysis habit. Knowledges need to be mastered and it can be realized with education, training and propaganda.

Educaitonal Training. The basic protection quality for trainees can be built by educational training. They can query anyone who posts request no mater anybody he claimed. They will check identity and authorization of anyone requesting information or operation. They will protect sensitive information and acquaint with data classificaiton system.

Strategy Making. Information security management strategy is about security problem in system adopted corresponding principles, requirement for security products, data protection methods and security running of important system. Responsibility of system management should be separated as far as possible and authority owning by system manager should be distributed reasonably.

Security Technology. Some simple network security technologies should be teached to user and security risk will be lowered effectively. So network security technologies will be applied actively and attack difficulty will be increased.

Conclusion

The scientific methods of mathematical statistics were put forward to study social engineering and its attack case. Each attack method and mean is analyzed comprehensively with its technology characteristics. It has application value in the practice no matter at operation or theory research and it will help to perform effective security protection measures aiming at social engineering attack.

Network Security Situation Awareness Based on Multi-source Data Fusion

Gang CHEN[1, a], JunPing CAI[1, a], Jun YANG[1, b]

[1]Academy of National Defense Information, WuHan, 430010, China

[a]email: cg0916_cn@sina.com, [b]email:yangjun_gfxx@sina.com

Keywords: Situational Awareness; Network Security; Information Fusion

Abstract. Network security situation awareness is an effective way to analysis security situation of complex network.The concept and model of network security situational awareness was introduced.A new model of network security situation awareness was proposed. Considering the characteristics of multi-source information in network security research, a security situation awareness algorithm based on information fusion was adopted. This algorithm advanced modified D-S evidence theory, gets the values of security situation awareness of network by data source level fusion, host-level fusion and system-level fusion. The results can reflect the general security state of network.

Introduction

With network going deep into social life, malicious activities aiming at network are growing and attacks such as Dos/DDos are becoming a growing threat. The traditional network security management is usually dependent on discrete deploying network security devices involving firewall, anti-virus and intrusion detection. So many problems including single function, larger warning information and too much irrelevant warning information will appear. Network security manager is hard to control being confronted with security situation of total network due to facing too much warning information. This would cause effective responses can't be taken in time.

Research of network security situation awareness is a hot field developing in recent years and it fuse warining information coming from security detection tools. It can also provides the foundation for network security managers with decision by analysing current network security situation and predicting attack behavior which will happen in next step. It is of great importance to imporving monitoring capability of network, emergency response capbility and predicting development tendency of network security.

Network Security Situation Awareness

Definition of situation awareness was firstly proposed by Endsley in 1988 [1]. It means precepting and comprehending environmental factor in a certain time and space. After that, future trends will be projected. The concept model ot the definition is shown as Figure 1.

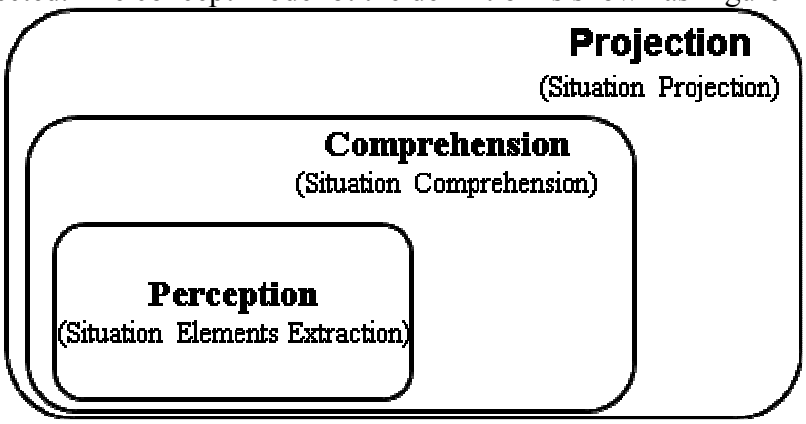

Fig.1. The concept model of situation awareness

The concept named network situation awareness was firstly proposed by Bass in 1999. The function model of network situation awareness based on multi-sensor data fusion based upon data fusion with joint directors of laboratories [2]. The function model is shown as Figure 2.

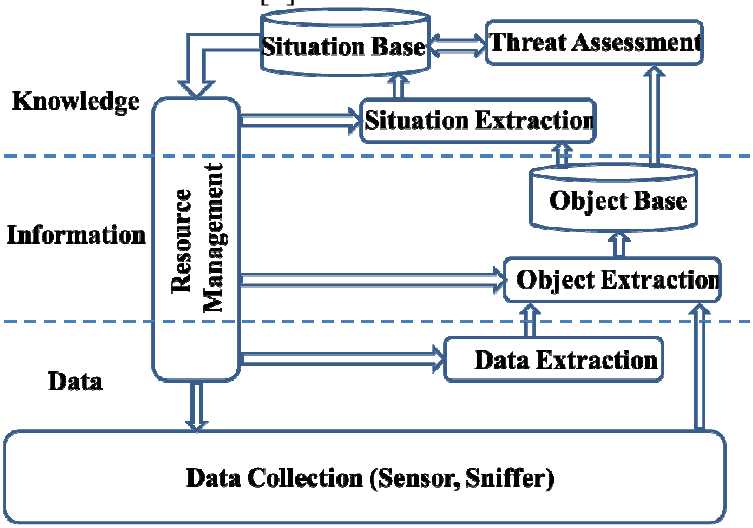

Fig.2. The function model of network situation awareness

Basing on different application fields, network situation can be divided into security situation, topology situation, transmission situation, and so on. But the current research of network situation is all about networksecurity situation [3].

In fields of network security, preception is extration process of network security situation element data. That is extracting data generated by all network security tools such as sensor and sniffer deploying in network. Comprehension is analytic processing process with extraction data. That is comprehending inner meaning of data by object extraction. Projection is predicting future trends of network security by threat assessment and knowledge reasoning process based on current and history information. Total situation of network security will be formed eventually by extracting and abstracting with data, information and knowledge.

Network Security Situation Awareness Model Based on Multi-source Data Fusion

In large and complex network, extraction data by situaion awareness are characteristics of multi-source, heterogeneous, big data, etc. Fusion processing with the data mentioned above is a difficult problem for situation awareness of large-scale complex network [4]. Combined with the concept model and function model shown as Figure 1 and Figure 2, a three layed model of network security situation awareness based on multi-resource data fusion is presented, which is shown as Figure 3.

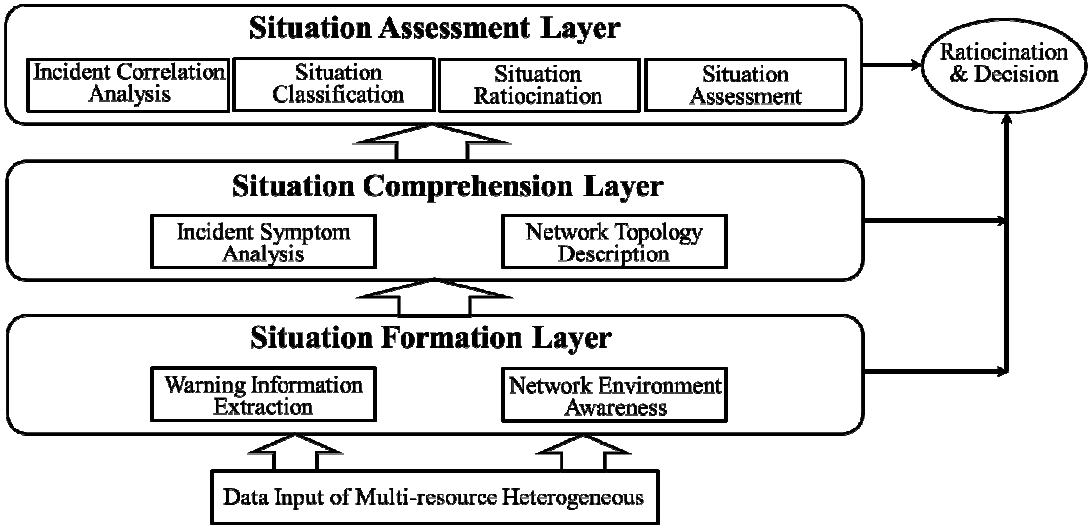

Fig.3. The network security situation awareness model based on multi-source data fusion

As it is shown in Figure 3, the first layer is network security situation formation layer, which performs physics collectting original data or signal. The environment scene can be described with current network topological structure and running state by correlation and processing. Then the data collection required by network security situation assessment will be formed.

As it is shown in Figure 3, the second layer is network security situation comprehension layer, which accepts data input forming in situation formation layer and completes refinement of target data. That is performing correlation analysis of target position, state, characteristic parameter and identity attributive information collected by multiple detectors with some criterion or algorithm. So precise expression of single entity target can be gained and the primary description and assumption of current network security situation can be performed.

As it is shown in Figure 3, the third layer is network security situation assessment layer, which determines current network security situation condition. Rational analysis and explanation will be performed combined with knowledge of field expert on the basis of network security incident symptom generating in situation comprehension layer and correlation analysis result of security incident. The network security situation condition is intention recognition of attack event, threat analysis and trend analysis of security situation.

Based on the model mentioned above, perception index of network security situatin can be reduced to two kinds called system structure information N and attack information I. The formal desciption of them are expressed as follow.

$N=(H,T)$, The H expresses collection of host node in system including server, terminal, all kinds of routers and switches. For some host node $h\in H$, it can be expressed as a four group $(id,wh,svhn,vulsh)$. The id is the unique identifier of host node and the wh is weight of host node. The $svhn$ is application server running in host node and the $vulsh$ is existing vulnerability in host node, which includes hardware vulnerability, wrong configuration, and so on. The T expresses network topological information which is collection of all physical connection relationship. It is expresses as $T\subseteq H\times H$.

$I=(I_p,I_d)$, The I_p expresses known attack information. For any known attack information $i_p\in I_p$ in system, it can be expressed as a four group $(id,vulsl,\log p,v)$. The id is the unique identifier of attack information and the $vulsl$ is needed by attack. The $\log p$ is log collection of known attack in detection device and the v is value of attack threaten limiting by $[0,1]$. The I_d expresses attack information detected. For anyone attack information $i_d\in I_d$ in system, it can be expressed as a dualistic group $(id,\log d)$ and the id is the unique identifier of detection device. The $\log d$ is log collection actually detected by detection device.

$SA=(N,I)$ is expressed as security situation value of system, which is formed by system structure information N and attack information I.

Data Fusion Algorithm

Data fusion is a data processing characteristic by multi-level and multi-layer, which mainly completes processing with data of automatic monitoring, interaction, correlation, estimation and combination coming from multiple information sources. Through integrated usage of multiple-source information, data fusion can get more objective and intrinsic knowledge of certain object or target.

A kind of three-level data fusion algorithm is adopted. The first level is data source level fusion, which is mainly solving fusion of multi-source warning information. It computes support rate $m(A)$ of some attack event happening by data source fusion based on detection log and host configuration information of multiple related detection devices. The second level is host level fusion, which computes security situation of host node with attack event happening support rate $m(A)$, attack successful support rate $S(A)$ and attack threaten. The third level is system level

fusion, which computes system security situation value with security situation of host node and weight of each node, and system security situation can be traced out.

Data Source Level Fusion. Fault and fail rate are higher on account of uncertainty of detection device. For judging a true attack event with some warning, support rate of some attack behaviour happening is needed to compute with fusion of these warning information. D-S evidence theory provides a synthetic method of related evidence and it can fuse evidence supplied by multiple evidence sources [5][6]. The D-S evidence theory is based on nonempty sets Θ, which is named as recognization framework. Each situation element comes form recognization framework $\Theta = \{N, A\}$. The N expresses normal behavior, the A expresses attack behavior and $NA = \phi$.

Host Level Fusion. Detection result indicates happening probablity of external attack and influence to host node is combined action with external attack information, interior fragility information of host node and threaten information of attack. So computing security situation of host node is need to fuse host situation elements with attack happening support rate $m(A)$, successful attack support rate $s(A)$ and attack threaten V.

System Level Fusion. The system security situation value will be gained by fusing security situation and weight of each host node in system level fusion.

The system security situation value SA will be computed by data resource level fusion, host level fusion and system level fusion. This value reflected total condition of system security and values of multiple time intervals can be used to drawing situation curve graph, with which system security condition can be mastered intuitively by security manager. Finally, system security trend can be predicted on the basis of the situation curve graph.

Conclusion

Based on provided network security situation awareness model, a multi-soure data fusion method adopting “data source level fusion-host level fusion-system level fusion” is presented to precept and assess security situation of network. It affords effective method for developing visual situation awareness system. In future work, multi-source data fusion algorithm needs to be optimized and the model should be proved by simulation examples [7].

Keywords: mobile e-commerce, 3G era ,strategy

Abstract. With increasing integration of mobile communication and internet technology, mobile e-commerce is begining to becomet useful supplement of traditonal e-commerce and shows strong vitality and development potential, relying on superiority in technology and application. The paper presents current situation of mobile e-commerce in 3G era, analyzes the problems, and puts forward corresponding strategies and rational suggestion.

Introduction

With the coming of 3G network, e-commerce mode is facing new revolution, the rising of mobile electronic business. The so-called 3G, the abbreviation of 3rd generation, shorted of the third generation mobile communication technology, refers to the cellular mobile communication technology for high speed data transmission. The 3G service can transmit sound at the same time(call) and data information(e-mail, instant messaging and so on), which characteristic is providing high-speed data service.

Mobile commerce (M-Commerce) refers to the electronic commerce of B2B, B2C or C2C through mobile phone, PDA, handled computer and other wireless terminals. It perfect combines the internet, mobile communication technology, the short distance communication and other technology, so that people can carry out a variety of business activities at any time and any place, realize online and offline shopping and transaction, electronic payment and various business activities, financial activities and related service activities whenever and wherever.

Advantages of mobile e-commerce

Mobility. The traditional electronic commerce is limited by network linear and terminal equipment fixed, but mobile e-commerce with wide wireless network and mobile communication equipment can effectively eliminate the distance obstacle. Mobile e-commerce can create more efficient interactive information, and use mobile communication and real-time communication directly oriented to users to breakthrough the limitation of online communication efficiency, so as to provide unlimited mobile service for users.

"4A" effect. The mobility of mobile e-commerce, the most significant feature, should be reflected in that anyone has access to information communication and realizes any service at any place and anytime. "4A" effect develop greater free scale business environment for mobile e-commerce, reduce the requirement of traditional electronic commerce to equipment and network environment, and reduce the threshold of users' participation.

Commercial value changes. Investigation report of development situation of China mobile internet shows that in Chinese 356000000 mobile phone users, intelligent mobile phone users reach 190000000. It makes development space of mobile e-commerce further increased. Because the characteristic of mobile communication equipment make each mobile terminal represent a certain consumer, it reflects its special business resource and value. In the modern business environment cored as the customers, the concern to internet uses turns more to mobile communication consumers of doubling population, which is the effective transformation of commercial value.

Problems existing in the development of mobile e-commerce

The consumption concept is too traditional. Influenced by traditional ideas, some people still hold wait-and-see attitude. Developing mobile e-commerce is not only a major change, but also a revolution of commodity trading idea. The traditional shopping way, selling cash-and-carry, has been ingrained in the thought of most consumers, but online electronic payment cannot be accepted. Therefore, consumption habits formed long term and inherent payment mode is the threshold in the growth process of fast service.

Laws and regulations are not perfect. Mobile e-commerce, as a new business mode, will inevitable bring a series of legal issues. But the relevant law is electronic signature law promulgated in April, 2005. Compared with foreign countries, the existing laws and regulations are far. The development of mobile e-commerce in our country is still in initial stage, so the relevant laws and regulations have not been introduced, which makes problems about mobile e-commerce trade, tax and security issues inextricability. Therefore, there is certain difficulty in protecting basic rights and interest of participant in mobile e-commerce.

Safe risks are still the key. Safe problem is the core and key restricting the development of mobile e-commerce, which is a universal phenomenon. Due to security concern, some consumers step back to mobile e-commerce. The wireless channel, an open channel, gives wireless users communication freedom and flexibility, and also brings many unsafe factors. Personnel information registered in the network may be stolen and tampered, which is security problem of mobile network; account number and password of bank card input at the time of payment may be stolen, which is security problem of payment system; the mobile phone may be installed software stealing users' information, which is security problem of mobile terminal. So how to establish efficient and uniform safety standards has become the problem of mobile e-commerce development needing to be solved.

Awareness of using mobile means is not high. Investigation report of China mobile internet development shows that application permeability of overall mobile internet in 2011 increased, communication application and information obtaining lead the development while the entertainment and business application developed relatively slow. Mobile phone instant communication and micro-blog, the representative of communication application, is the mainstream application to promote the development of mobile internet at this stage. The traditional consumption idea is difficult to change in the short term, and few consumers support mobile e-commerce development project, such as online payment, online banking, mobile phone booking, network group purchasing. The awareness of using mobile means is not high.

Value application of mobile e-commerce is not complete. Although the scale of mobile internet users is growing fast as well as mobile phone users, the development of mobile e-commerce market is only depends on the increasing number of users, but the developing and mining of mobile e-commerce application value. If the mobile service only focuses on the information inquire entertainment and so on, the industry chain of mobile e-commerce can not be further improved, and users' service demand and the business profit demand can not be satisfied, which reflects the value application of the mobile e-commerce is not complete and mobile operators should develop large-scale mobile service.

Mobile application development lack attractiveness. With the appearance of new mobile technology, telecom operators join the application field of e-commerce, and mobile e-commerce mode also emerges as the times. Mobile e-commerce lead by telecom operators is in its infancy, technology development of mobile communication is far less powerful than software development ability of Network Company. Operators don't have experience in e-commerce operation and lack deep analysis to the market and user need. With the continuous introduction of 3G service implementation, it is difficult to develop the application service of mobile e-commerce targeted to customer demand, so mobile service application development lack attractiveness.

High data fees reduce the willingness to pay. Investigation report of China mobile internet development shows that mobile phone users' demand for wireless network traffic is not large. Most users use mobile phone to hang QQ and brush micro-blog, while mobile users are very sensitive to the

wireless network traffic and the corresponding price. The mobile phone lack Software tool types and contents of the corresponding version, leading to that users are unwilling to pay for internet products. More than 80% mobile phone users haven't bought mobile phone application service in the past six years, the higher fees of mobile internet tariff influence the development speed of mobile e-commerce.

Development strategies of mobile e-commerce

Strengthen the construction of correlation laws and regulations, and create harmonious legal industry environment. At present, there are no targeted laws and regulations to guide 3G mobile e-commerce industry, so the competition in mobile e-commerce industry will be so hot that trade disputes will increase under the background of financial crisis. Once trade disputes and industry problems occur, there is no uniform standard to handle with and all the participants' rights will be in the unprotected state. What's more, the economic crisis lash, e-commerce industry develops too rapidly, industry competition increase, external shocks strengthen, which all call for related laws and regulations. Creating harmonious legal industry environment is extremely urgent.

Improve the industrial chain and promote the development of correlation industry. First, improve the industry chain to seek common development. 3G mobile e-commerce is proposed on the basis of traditional e-commerce and depends on the new 3G network. So it should carry out depth cooperation from the level of industry, for example, jointly establish and perfect 3G network, expand e-commerce market using industry, expand online good, build brand protection and credit improvement, carry out joint promotional activities, enhance consumption experience of user terminal, etc.

Improve the customer terminal service and enhance the directional effective communication. Compared with the traditional e-commerce terminal equipment, terminal equipment function of 3G mobile e-commerce is more powerful. Mobile phone users and other targeted consumers use these equipments to make personal touch and customize information according to personal characteristics and interests. According to database containing a large number of active customers and potential customer information, Mobile business can make full use of the advantages of 3G network to carry out more targeted information advertising through personalized SMS, MMS and other service activities, and improve the directional effective dissemination of advertising information. Second, cooperate with mobile phone manufacturers to joint research mobile e-commerce trading platform software. From the view of users, develop private, timeless, convenient and efficient terminal software to improve consumption experience of user terminal and perfect customer terminal service.

Establish the network security strategy and enhance customer trust. How to guarantee the security of e-commerce activities is the core problem of e-commerce development. After the outbreak of the financial crisis, consumer behavior and enterprises' investment behavior are becoming cautious. So the development of 3G mobile e-commerce must first solve the problem of network security and thoroughly remove the future problem of the consumers. The characteristic of e-commerce, virtual trade platform, determines that it should carry out business activities through network. Mobile e-commerce mainly relies on mobile phone, panel computer and other terminal devices to transmit information by wireless channel. The wireless channel is an open channel, which makes communication flexible, mobile, vulnerable and instable. Although the birth of 3G network greatly alleviate this situation, however, protecting consumers' personal information and commercial secret is still the problem we should pay attention to. We could solve the network security fundamentality through technological innovation, and also can promote network security of e-commerce through technological innovation.

Strengthen industry self-regulation and jointly cope with external force. Compared with foreign 3G mobile e-commerce industry, our 3G mobile e-commerce industry is still in the primary stage of development. The outbreak of financial crisis makes all the countries focus on China and hope to get rid of the economic crisis by China, a consumption power with 1.3 billion populations. Facing the

impact of external force, the e-commerce industry of our country should unite as one, jointly cope with, create industry standards, strengthen self-discipline, upgrade the industry level and deal with foreign competition. Specifically speaking, we should spur with long accumulation, strictly control speculation and develop in the steady.

Improve the correlation industry. Virtual 3G mobile e-commerce extremely relies on the logistics distribution system. Over the years, logistics and distribution network system in China is not perfect, which is a bottleneck restricting the development of mobile e-commerce. If 3G mobile e-commerce wants to have new breakthrough and development in the long run, we should develop and improve the logistics distribution network system. Provide the most convenient and safest delivery service to the minimum inventory level; choose the nearest distribution outlets and the most convenient transportation means from the nearest delivery route to make the goods reach the hands of consumers completely.

Improve the personnel training system and promote industry soft power. In 21the century, talents are the most important. Mobile e-commerce, as an emerging industry, should pay attention to the training of professional talents for rapid development. Mobile e-commerce, the multiple of business management and information technology, needs business talents with professional business knowledge in terms of market application. But the induction of 3G mobile network urgently requires practitioners to have technical knowledge. Many factors make the choosing and training of 3G mobile e-commerce practitioners become the priority among priorities. Specifically speaking, fist, cultivate by school. Set up courses related to the network technology in the e-commerce subject and related subjects of all universities, solving the problem of talent lack from the source. Second, in view of the current 3G mobile e-commerce practitioners, enhance the quality of employees through short-term professional training. Third, enterprises and school cooperate with each other to cultivate 3G e-commerce talents directly.

Conclusions

In 2003, SARS brought development opportunity to traditional electronic commerce. We have reason to believe that in the post financial crisis period, 3G mobile e-commerce will rely on favorable environment of economy, politic and industry to cope with the challenge positively and effectively to realize the leap development of e-commerce industry.

Research And Analysis Process Of Android Communication Platform In AIDL Model

AnMing Hu

Tianhe College of Guangdong Polytechnical Normal University

GuangZhou 510540 E-mail: anminghu@hotmail.com

Key words: Android, AIDL, interprocess communication

Abstract. AIDL is a android platform to describe the inter process communication interface description language, can simplify the process of data exchange between the format and data code.Research on AIDL communication mechanism has an important significance to the realization of the Android platform interprocess communication. This paper analyzed the AIDL model and the communication mechanism and gives examples to discuss.

Introduction

Android is a mobile platform Google development based on Linux operating system,The platform is open source, the advantages of stable, easy development etc,Affected by the developers, users and developers alike, has become the most widely used mobile intelligent platform. With the wide use of Android platform, all under the platform of Android application system based on also emerge as the times require, HoweverAndroid platform application development with the traditional Windows and Liunx, Interprocess communication is used as the underlying technology is very important in the operating system, to understand and grasp the inter process communication, is very important for the development of application system under Android platform.

In the traditional operating system, communication, realize the function of the system platform of resource sharing among multiple processes, is a very basic and important function of the application, At the same time, The important function of interprocess communication is the operating system kernel part。Android operating system is based on Linux, in the Linux process communication generally use the traditional IPC (Inter-Process Communication, IPC) model，And the IPC model to achieve the shared memory, pipes, message queues and socket etc., Although widely used IPC model, but the UID/PID data in IPC mode is filled by an application, the existence of poor reliability, easy to be tampered with, difficult to maintenance. In order to solve the problem of Android platform, the interface description language (AIDL). Implementation of interprocess communication through the interface and the proxy class methods, solve this problem.

AIDL (Android Interface Definition Language) is a Android system custom interface description language IDL, Is one of the common ways of implementation of interprocess communication in Android platform, AIDL grammar rules and similar Java language, without written by C++ interface, no mixed C++ compiler, simplifies the process of communication development. Belong to lightweight communication mechanism, with high efficiency, simple implementation.

The Principle And Process Of AIDL Implementation

AIDL language is a system level primitives, but the syntax structure and Java language is very similar, AIDL is mainly used to define access interface, no implementation process.

Table 1. The grammar characteristics.

Type	Explain	Need to introduce
The basic types of Java language	Including Boolean, byte, short, int, float and double etc.	FALSE
String	java.lang.String	FALSE
CharSequence	java.lang.CharSequence	FALSE
List	Among all elements must be supported AIDL data types	FALSE
Map	All the bond and element must be AIDL supported data types	TRUE
Other AIDL interface	Any other use of the interface type AIDL language generation	TRUE
The Parcelable object	An object that implements the Parcelable interface	TRUE

Unlike Java, AIDL allows you to define the direction of transfer function parameters, support three kinds of direction in AIDL: in, out, inout.

Identification of in parameters will be passed from the caller to the remote service;

Identified as out parameters from the remote service delivery to the caller;

Identified as inout parameters will be passed from the caller to the remote service, and from the remote service is returned to the caller.

The process of ADIL implementation according to the following steps:

to create the AIDL interface description file;

Through the Java interface to realize the remote service AIDL interface android.os.Iinterface interface;

And use the remote service binding;

The client calls;

In the case of AIDL communications, server generally consists of a AIDL file and a IService interface and the Service class, The IService interface is used to access method defined in AIDL, and IService must be a android.os.Iinterface interface, Service is the AIDL interface implementation class.

1) AIDL files are defined as follows:

```
package com.TestAIDL;
  interface IService {      int getAccountBalance();
     int getCustomerList(in String branch, out String[] customerList);       }
```

2) Implementation of the Iservice interface

Consisting of three parts in the Service interface AIDL interface to achieve its internal structure, The internal static abstract class Stub, Stub class and its subclasses are very important in the whole AIDL communication, is used to implement the AIDL interface implementation class, Stub must be implemented subclasses of Android.os.Binder and Iservice; Static inner classes Proxy, Proxy belongs to a class is provided to the remote service invocation interface class; Is the IService to achieve AIDL access interface method. The Iservice interface part of the code is shown as follows:

```
public interface IService extends android.os.IInterface
{public static abstract class Stub extends android.os.Binder implements com.lifeblood.ITestService
{private static final java.lang.String DESCRIPTOR = com.TestAIDL .ITestService";
public Stub(){this.attachInterface(this, DESCRIPTOR);}
private static class Proxy implements com.lifeblood.ITestService
{private android.os.IBinder mRemote;
…….
int getAccountBalance();
int getCustomerList(in String branch, out String[] customerList);
```

/Static inner classesProxy /……..
public int getAccountBalance();
public int getCustomerList(in String branch, out String[] customerList);

3）Implementation of the TestService class

The TestService implementation class, is a common Service class Android.os.Service class Android, Is an important implementation class implements the AIDL interface, but the process is a bit special, is defined by the ItestService.Stub type member variables, The method of calling Iservice interface, which is defined in the AIDL interface method. Following this kind of mechanism:

public class TestService extends Service {private Context mContext = null;
private IService.Stub binder = new Stub(){ private String name = null;
public int getAccountBalance() throws RemoteException { return 1000;}
public int getCustomerList(String branch, String[] customerList)
throws RemoteException { customerList[0] = name;
System.out.println("Name:"+branch);return 0;} };

4）Start the Service service in the Activity class

In this case the Service is to provide remote services, without the need for access to the local Activity, so Service can be activated using the Intent class, the code is structured as follows:

Intent service = new Intent(this, TestService.class);startService(service);

5) The AndroidManifest.XML Configuration

The AndroidManifest.XML file configuration is very important, the remote service access by other processes to service, is using the AndroidManifest file name for the configuration of positioning, the Service configuration is as follows:

<service android:name="TestService" android:process=":remote"> <intent-filter>
<! -- AIDL full path name. Must specify the class name, the client can pass the AIDL to find the implementation class -- >
<action android:name=" com.TestAIDL.TestService" /></intent-filter></service>

6) The Client Process Calls

The client process calls and similar to JNDI method, by implementing the ServiceConnection interface of remote service binding, get the Service object, so as to realize the call, the client instance also need to copy the AIDL interface file. The following ServiceConnection structure:

public void onServiceConnected(ComponentName name, IBinder service) {
tService =TestService.Stub.asInterface(service);
System.out.println("Bind Succeed:"+tService); }
public void onServiceDisconnected(ComponentName name) {tService = null; } };

7) The Test Run

The procedure of the program are as follows:
The first running TestService server
Then run the AIDLClient client
Click AIDL to get Service service connection binding, and display call information.

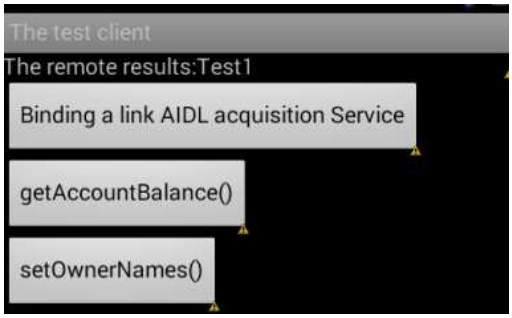

Fig.1 To obtain Service effect

Conclusion

The AIDL interface description language grammar structure and Realization principle, And the implementation process of AIDL in remote call process,Configuration method and correlation are analyzed and discussed.

AIDL is based on object-oriented design implementation of interprocess communication, and AIDL language with primitives rule system in Android platform, Android system development process, inter process communication provides a more simple and convenient access model.

Keywords: server push mode; analytic hierarchy process; server performance; server load

Abstract. First of all, three current server push modes are elaborated in this paper, including a detailed analysis and comparison. Due to a single server push mode is used by the current push frame, most application requirements can not be meet. Push techniques based on analytic hierarchy process is proposed in this paper, which selects optimal push mode in different situations by theory of operations research. This method not only improves server performance but also reduces server load. Finally, experimental results show that the proposed method is superior to other single mode.

Introduction

With the rapid development of internet network technology, internet technology has entered a mature stage. In recent years, internet has come to be the primary method for people to get information. In web technology, the real-time information transmission has a wide range of application, which including device monitor, network conference, collaborative work and so on. In order to realize these applications, the server must push change message to client [1, 2].

As a new message push technology, web-based push technology can push change message to the client asynchronously. At present, appropriate browser plug-in are generally required to be installed in client with these techniques, so deployment, maintenance and security issues will bring a series of problems. According to different client request types, this paper propose a real-time message push model based on Http, which can select optimal push technology in different situations by theory of operations research.

Three Http-based Push Modes

A. Ajax-based Polling Mode

Http is stateless and one-way protocol, so users can only send request to the server though the client, and the server returns response message after processing by the server. Ajax-based polling regularly refers to set timer in the client, and periodically send asynchronous request to the server from a web page. After the request is processed by the server, the client will parse the returned XML and refresh partial page [4].

In order to ensure real-time of data acquisition, most invalid and redundant responses send to the client frequently. This mode is not only a waste of server computing resources, but also occupies the network bandwidth and the invalid net flow. If we choose to adjust the polling frequency, which means increasing time intervals to reduce the load on the server, real-time of data can not be guaranteed and the server pushes requirements can not be achieved.

B. Ajax-based Long-polling Mode

Ajax-based long polling mode means when a request sends to a server asynchronously by Ajax in the background will not be return immediately, but maintain the original HTTP link in the server for some time until events arise or connection timeout. The process flow is shown in Fig. 1.

The main advantage of this mode is to maintain a long connection between the client and server, but server thread and memory resource consumption will increase after requests are blocked. When the number of connections increases, the response speed of the server will be affected. This mode not

only makes full use of the request processing time in the server, but also makes the very short stay as long as possible by blocking mechanism. This mode reduces the average number of requests, so it is better push technology presently.

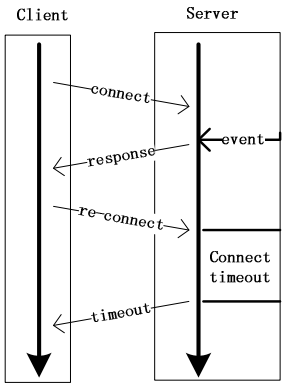

Fig. 1 Ajax-based long-polling mode

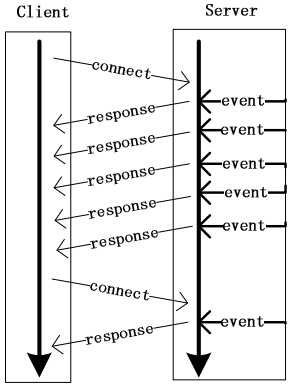

Fig. 2 Iframe-based Streaming Mode

C. Iframe-based Streaming Mode

Iframe-based streaming mode is a technology which hides the iframe in web page and sets its src attribute as the never closed connection request. The server continuously sends data to the hidden iframe of the client, and the client will refresh partial page according to the received data. From Fig. 2, the server and the client always remain connect. When events are generated from the server, the client can receive data from the server directly without re-establishing the link. This mode can save more setup link time and network bandwidth compared to the two modes above.

D. Comparison of Three Modes

From Table 1 of push technology in the three modes we can see, each kind of push technology has its own advantages and applicable scene. Ajax-based polling mode is applicable to scenes of server events with a fixed interval; Ajax-based long polling mode is applicable to scenes of server events with short interval and high real-time requirements; Iframe-based streaming mode is applicable to scenes of server events with frequent interval and high real-time requirements.

Table 1 Comparison of polling, long-polling and streaming

Mode	Polling	Long-polling	Streaming
Memory consumption	low	high	relatively high
Real-time	worse	good	very good
Request frequency	high	normal	low

AHP-based Push Mode

A. Analytic Hierarchy Process

AHP (Analytic Hierarchy Process) was put forward by the operational research experts of USA, which is an effective multi-target decision method combining qualitative analysis with quantitative analysis [5, 6]. The problem is divided into the target layer, criterion layer and decision layer. To avoid multiple factors confusing decision-making, AHP makes the decision process more clear and reasonable by hierarchical analysis of problems [7]. Steps of the weights of attributes calculated by AHP are as follows:

(1) The establishment of evaluation system hierarchy structure. Make clear of the problems to be analyzed, divide the factors contained into different layers to establish a hierarchical structure.

(2) Structure of comparison matrix. Judgment matrix means the relative importance of a factor in this level compare with last level.

$$A=\left[\frac{\beta_n}{\beta_m}\right]_{m,n},\ B^{CPU}=\left[\frac{C_i^{CPU}}{C_j^{CPU}}\right]_{i,j},\ B^{Mem}=\left[\frac{C_i^{Mem}}{C_j^{Mem}}\right]_{i,j},\ B^{Time-Delay}=\left[\frac{C_i^{Time-Delay}}{C_j^{Time-Delay}}\right]_{i,j},\ B^{Event-frequent}=\left[\frac{C_i^{Event-frequent}}{C_j^{Event-frequent}}\right]_{i,j},$$
$$B^{Connect-count}=\left[\frac{C_i^{Connect-count}}{C_j^{Connect-count}}\right]_{i,j} \quad (1)$$

We can describe the elements $(\beta_m^*,\beta_n^*)\in\{\beta_{CPU}^*,\beta_{Mem}^*,\beta_{Time-Delay}^*,\beta_{Event-frenquent}^*,\beta_{Connect-count}^*\}$ and thus $(C_i^*,C_j^*)\in\{C_{Polling}^*,C_{Long-Polling}^*,C_{Streamin\,g}^*\}$

(3) The calculation of the weights. The weights calculation means the calculation of the maximum largest eigenvalue and eigenvector of the judgment matrix. Though the eigenvalue method $A\tilde{\omega}=\tilde{\lambda}_{\max}\tilde{\omega}$ to calculate eigenvector $\tilde{\omega}$, and $B\omega=\lambda_{\max}\omega$ to gain eigenvectors ω. Then the eigenvalue and eigenvector in three Http-based push modes can be described as $\lambda_{\max}$, $\lambda_{\max}^{CPU}$, $\lambda_{\max}^{Mem}$, $\lambda_{\max}^{Time-Delay}$, $\lambda_{\max}^{Event-frenquent}$, $\lambda_{\max}^{Connect-count}$ and $\tilde{\omega},\omega^{CPU}$, ω^{Mem}, $\omega^{Time-Delay}$, $\omega^{Event-frenquent}$, $\omega^{Connect-count}$.

(4) Consistency of judgment matrix. In order to maintain the consistency of judgment thinking, consistency of judgment matrix is required when AHP method is used. The calculation of the consistency is as follows:

$$C\cdot I=\frac{\lambda_{\max}-n}{n-1} \quad (2)$$

The coefficient C can be used to check the consistency of judgment matrix as shown in the following Eq. 3：

$$C\cdot R=\frac{C\cdot I}{R\cdot I} \quad (3)$$

Where $C\cdot R$ is consistency index, when $C\cdot R<0.1$, we accept the judgment matrix.

(5) So the hierarchy weight can be finally calculated as:

$$\mu=\left[\omega^{CPU}\quad\omega^{Mem}\quad\omega^{Time-Delay}\quad\omega^{Event-frenquent}\quad\omega^{Connect-count}\right]_{5\times5}\tilde{\omega}_{5\times1} \quad (4)$$

B. AHP-based Push Frame

Server push technology is based on the browser platform, which can push abundant information to the client browser server actively and meet the needs of the real-time required information for client. With the continuous improvement of server push technology, the mature server push technology framework appears. These technical frameworks focus on issues of server performance, and use a single server push mode for all service requests without paying attention to the specific application needs and ignoring the differences between different application requirements.

In this paper, the differences in the different application requirements are considered. In order to optimize the performance of the overall application and make full use of system resources, we can perceive the change of application status and adjust server push mode dynamically by AHP method. The main considerations in AHP analysis layer include event frequency, CPU resource, memory consumption, the number of user connections, network bandwidth and so on. The AHP-based push frame in this paper is shown as in Fig. 3.

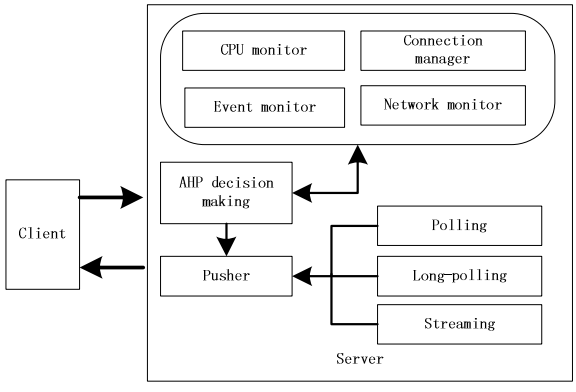

Fig. 3 The structure of AHP-based Push Frame

Experimental results

In the same LAN environment, the three modes in above section and the mode proposed by the paper are simulated respectively. In order to simulate a high number of clients, we use open source tool Grinder, which is an open source load generation and data collection tool, providing an internal TCP Proxy, allowing to record events sent by the browser and later replay them. CPU usage and triptime is two major quality indexes of service concerned by us. We define triptime as follows:

$$\text{Triptime} = |\text{Data Creation Date} - \text{Data Receipt Date}| \tag{3}$$

Mean triptime and server CPU usage results are presented in Fig. 4 and Fig. 5：

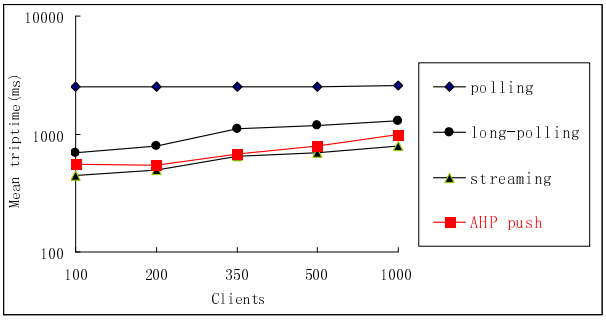

Fig. 4 Mean triptime result

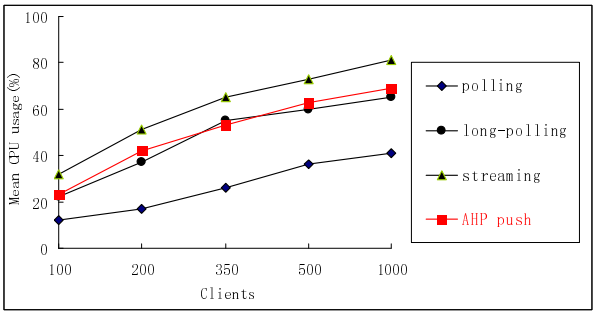

Fig. 5 Mean CPU usage result

From the results it can be found, triptime of streaming and long-polling method are shorter than that of polling method if there is fewer number of client. This is because in the streaming and long-polling mode, the server can send message to the client immediately after the change event, while the polling mode is bad real-time capability. We also find that long-polling mode produce data flow more than streaming mode in our experiment, because client will be forced to send request after receiving data in long-polling mode. Triptime of streaming mode is the shortest in three modes, the flow can be controlled at a minimum in this mode. With the increase of the number of clients, the difference between streaming mode and other two modes will become more obvious.

The AHP push mode proposed in this paper realize the fusion of three modes in an application, so that each request is applied to be push in an appropriate way and the precious resource of the server will able to be used effectively. In ensuring the overall quality of service at the same time, the application of different allocation strategies can improve server performance and reduce the server load in a certain extent.

Summary

AHP-based Push Mode by this paper orders appropriate server push technology for different types of requests, which can improve quality of application service and server performance more effectively than single push mode.

Information Management of Digtal Libirary Based on Data Mining

HUANG Suyu[1, a]

[1]Wuhan Donghu University, Wuhan 430063，China

[a]huangsuyu425@126.com

Keywords: Data mining, digital libirary, Internet, research, Web data, information management;

Abstract. With the development and maturity of digital libirary, the Internet has become more and more intelligent, humane and social. It began gradually infiltrated into every aspect of people's lives, influence and change people's way of life. digital libirary era as representative products -- information management has been the suddenness of a thunderbolt swept the interaction information user global information managementing platforms began showing explosive growth trend however, and people are facing information explosion but the core concept of wisdom barren embarrassing situation. [1]

Introduction

Digital libirary era is to take the customer as the center, pay attention to the user experience and user interaction, therefore, how to effectively collect and use information management platform of Shanghai amount of user mutual information, and dig out valuable knowledge from the information management, in order to improve the user experience, become the hot topic of Internet industry research and discussion in order to improve the use of information managementing users interactive data rate, the paper tries to apply the Web data mining technology into information management applications to the mining information management characteristics and in-depth study of relevant theories of personal tag cloud and exploration of Web data Cable, putting forward the innovative concept of information management platform based on individual tag clouds, and the design and implementation of the main information management personal tag cloud system in this paper includes the following two aspects: the first part of theoretical research, firstly, a detailed analysis of the related theory of data mining and Web mining, and summarizes the main techniques the classification of data source function process and key problems.

The use of Web data mining laying the related characteristics of the technology with a good theoretical basis and detailed summary analyzes the main content and structure elements of information management expression characteristics and function etc. [5]

It also helps us to fully understand the development status of information management architecture model of user demand and facing major problems for the development of information managements based on individual tag cloud to provide a good platform second theoretical basis for the practical research, mainly reflected in the design and implementation of personal tag cloud system information management based on the first in-depth research and design of the pretreatment method of information management data, mainly divided into the log preprocessing And the text pretreatment two parts to elaborate, for the text mining provides high quality data sources next step detailed introduces the design and implementation of personal tag cloud, and summarizes the practical significance of creating information managements based on individual tag clouds, pointed out the direction for the future research. [4]

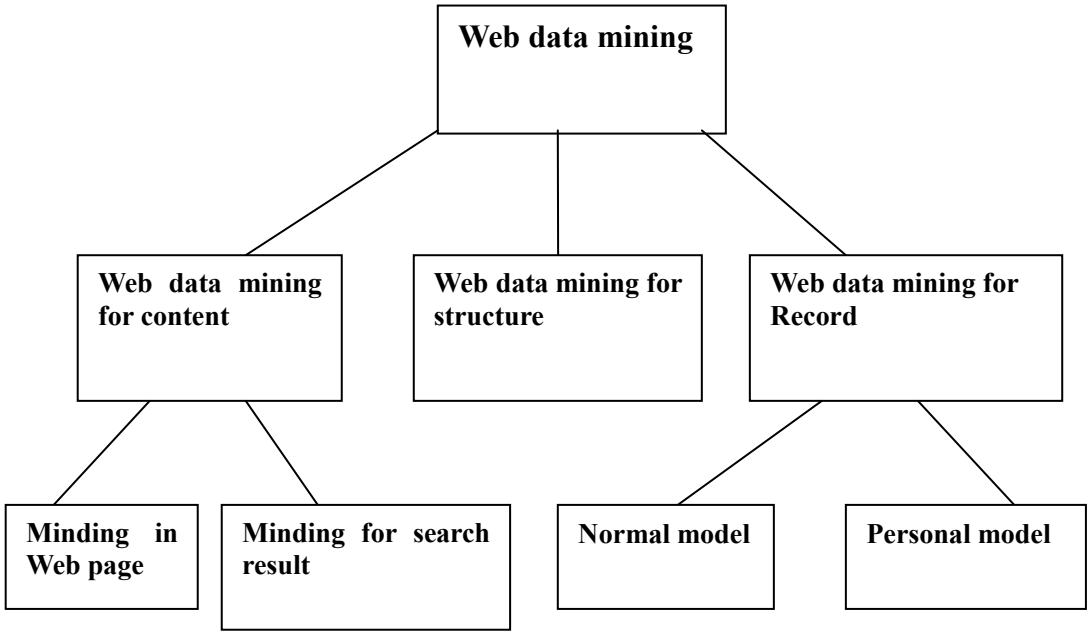
Web data mining

(1) The concept of Web data mining

Data mining is a process to reveal the implicit, previously unknown from large amounts of data in the database and the potential value of information. [2]Web data mining is the application of data mining technology in the Web environment is to discover the potential, useful model or information

from Web documents and Web activity. It is a comprehensive technology, involves many fields of Internet, artificial intelligence, computational linguistics, information science, statistics etc.

(2) The type of Web data mining



Support (F- I) =P (F∪I) (formula 1)

Confidence (F- I) =P (FBI) (formula 2)

For example, association rules: (X. "20... 29) "^income X. 20K"... 29K ") buys (X." HR_PLAYER "[Support=2%, confidence=60%]) Where X is the variable, representing the tourists, the rule analysis database instance 2% (support) in 20-29 years, the annual income of 20k-29k. There are 60% possibilities of this age and income groups of customers to buy the HR player (the degree). [1]

Diversity of Web information in electronic commerce determines the diversity of the data mining tasks. According to the Web treatment of different objects, Web data mining can be divided into the following three types [1]:

a. Web content mining (Web Content Mining): can be divided into the Web search results page content mining and mining. The former refers to mine the data on Web. The latter refers to a search engine based on mining, search results, and to get more accurate and useful information. Web content mining methods commonly used are Web OQL and Ahoy.

b. Web structure mining (Web Structure Mining): can be divided into a hyperlink mining, URL content mining and mining. The whole Web space, useful knowledge not only included in the Web page content, and included in the structure of the page. Web structure mining is the mining structure mode link potential Web, is a mining structure of Web page directory path hyperlink relationship, document structure, document in the URL. The Page2Rank method is the use of inter document links to find related pages Web, the algorithm is flowed:

Split_Infox(X) = -SUM ((|T|/|Ti|)*LOG (|Ti|/|T|))

Gain ratio(X) = Gain(X)/Split_Infox(X)

WTX-W0 >0 X∈ω1 -WTX-W0 <0 X∈ω2

P(Y | X) = P(X | Y)P(Y) / P(X)（1-1）

P (Xi | Yi) = (nc + mp) / (n + m)

c. The Web usage mining (Web Usage Mining): can be divided into general access pattern mining and personalized service pattern mining. It is from Web access logs extraction interest

pattern. Each server in the WWW has retained the access log, recording user access and interaction information. Analysis of these data can help understand user behavior, improve the structure of the site, or to provide personalized service to users [1].

Application of Web data mining technology in electronic commerce

(1) To retain the old customers, and tap potential customers

Through Web mining, electronic commerce operator can learn each visitor personal interests, to fully understand customer needs, providing customized products according to the unique needs of each customer, and according to the dynamic demand to customers to do page recommendation, adjust the Web page, increase customer satisfaction, customer retention time prolonged, reach retain customers to. By mining the Web log records, can be the first to classify existing visitors from its classification, and then determine whether a new client is a potential customers.

(2) Product marketing strategy formulation, optimization of promotional activities

Mining and sales through access to goods, enterprises can gain access to regular customers, identify customer life cycle, according to the change of the market, develop appropriate marketing strategies for different products [4].

(3) To reduce operating costs, improve the competitiveness of enterprises

The owner of the electronic commerce through Web data mining, can obtain reliable market feedback information, careful analysis of customer behavior in the future, for e-commerce marketing activity; can be decided according to the pattern of advertising a product of the visitor's browsing interest position, increase advertising targeted advertising, improve the rate of return on investment, thereby reducing operating costs, improve the competitiveness of enterprises.

Conclusion

Information management has become the most popular application of the digital libirary era; this paper focuses on how to apply Web mining technology to the analysis of online information managements. Meanwhile, it also introduces the Web mining and information management technology and concepts, and shows how the Web mining technology used in information management analysis. The analysis process of Web mining information management, and analyzes the future research direction in this field and trend are also involved in this paper.

Research on E-government Model Based on Big Data

Yiqing Lu[a]

School of Information Management, Beijing Information Science and Technology University, Beijing, 100192, China

[a]email: luyiqing@126.com

Keywords: E-government; Big data; Cloud computing; Public management

Abstract. The rapid development of big data will greatly change the government's management mode. Each country in the world has issued various policies to deal with the development of big data, and our government also attaches great importance to the industry of big data. The e-government model based on big data proposed in the paper raises new ideas for the innovation of e-government affairs.

Introduction

Big data, a general term for the massive amount of digital data being collected from all sorts of sources, is too large, raw, or unstructured for analysis through conventional relational database techniques. Almost 90% of the world's data today was generated during the past two years, with 2.5 quintillion bytes of data added each day. Moreover, approximately 90% of it is unstructured. Still, the overwhelming amount of big data from the Web and the cloud offers new opportunities for discovery, value creation, and rich business intelligence for decision support in any organization. Big data also means new challenges involving complexity, security, and risks to privacy, as well as a need for new technology and human skills. Big data is redefining the landscape of data management, from extract, transform, and load, or ETL, processes to new technologies (such as Hadoop) for cleansing and organizing unstructured data in big-data applications.

Although the business sector is leading big-data-application development, the public sector has begun to derive insight to help support decision making in real time from fast-growing in-motion data from multiple sources, including the Web, biological and industrial sensors, video, email, and social communications. Many white papers, journal articles, and business reports have proposed ways governments can use big data to help them serve their citizens and overcome national challenges (such as rising health care costs, job creation, natural disasters, and terrorism).There is also some skepticism as to whether it can actually improve government operations, as governments must develop new capabilities and adopt new technologies (such as Hadoop and NoSQL) to transform it into information through data organization and analytics[1].

Introducing of Big Data

Big data is the term for a collection of data sets so large and complex that it becomes difficult to process using on-hand database management tools or traditional data processing applications. The challenges include capture, curation, storage, search, sharing, transfer, analysis and visualization. The trend to larger data sets is due to the additional information derivable from analysis of a single large set of related data, as compared to separate smaller sets with the same total amount of data, allowing correlations to be found to "spot business trends, determine quality of research, prevent diseases, link legal citations, combat crime, and determine real-time roadway traffic conditions."

As of 2012, limits on the size of data sets that are feasible to process in a reasonable amount of time were on the order of exabytes of data. Scientists regularly encounter limitations due to large data sets in many areas, including meteorology, genomics, connectomics, complex physics simulations, and biological and environmental research. The limitations also affect Internet search,

finance and business informatics. Data sets grow in size in part because they are increasingly being gathered by ubiquitous information-sensing mobile devices, aerial sensory technologies (remote sensing), software logs, cameras, microphones, radio-frequency identification readers, and wireless sensor networks. The world's technological per-capita capacity to store information has roughly doubled every 40 months since the 1980s; as of 2012, every day 2.5 exabytes (2.5×10^{18}) of data were created. The challenge for large enterprises is determining who should own big data initiatives that straddle the entire organization.

Big data is difficult to work with using most relational database management systems and desktop statistics and visualization packages, requiring instead "massively parallel software running on tens, hundreds, or even thousands of servers". What is considered "big data" varies depending on the capabilities of the organization managing the set, and on the capabilities of the applications that are traditionally used to process and analyze the data set in its domain. "For some organizations, facing hundreds of gigabytes of data for the first time may trigger a need to reconsider data management options. For others, it may take tens or hundreds of terabytes before data size becomes a significant consideration." [2]

Big data is becoming the new power to promote the social innovation in the 21st century. Meanwhile, the reform caused by the big data also promotes the development of e-government in each country in the world [3-5]. In May, 2010, Australian government issued "open government declaration" to increase the transparency of the government. Currently, over 30 countries in the world have joined the rank of open data. Under the promotion of global open data, in November 2011, EU clearly proposed the strategy of open data. On March 29, 2012, US Obama government proposed "big data research and development plan", thus improving the understanding on the big data to the national development strategy level, proposing to breakthrough the core technology in the big data processing field, quickening the innovation of science and engineering fields, and strengthening US' national competitive development plan in the information age. In July 2012, the United States issued the big data government white paper "Big Data Promotes the Development: Challenge and Opportunity", pointed out that the big data is a historical challenge for the United Nations and each government, discussed how to use the big data resource including the social network for the benefit of mankind. The United Nations points out that the big data era has arrived, people can use the great wealth of data resources including old data and new data to conduct the unprecedented real-time analysis on the social population. With the example that the social network activity growth in Ireland and US as the early warning signs of the rising unemployment, the report shows that if the government can reasonably analyze the grasped data resource, it will rapidly respond with the data. The report also explains how does the big data help the government better respond to the social and economic indicators, such as income, unemployment, food price, etc.

At present, our country has issued a series of policies to promote the development of big data industry, including "the 12th five-year plan" national strategic emerging industry development plan, Internet of Things "the 12th five-year" development industry planning and NDRC's opinion on strengthening and improving the national e-government project, etc. In December 2012, Guangdong Province firstly started the big data strategy in the country, and issued "Program to Implement Big Data Strategy Working in Guangdong Province". The launch of the policies and plans indicate that our government attaches great importance to the big data industry, and the development strategy objective is clear. The situation makes our independent innovation leading enterprise usher in a great development opportunity. Therefore, how to make the big data play greater value in the government information project becomes the hot topic at present.

Influence of big data on e-government

The Obama Administration recently unveiled its Big Data Research and Development Initiative to "improve [American] capability to extract knowledge and insights from large and complex

collections of digital data; harness these technologies to accelerate the pace of discovery in science and engineering; strengthen national security and transform teaching and learning."

Big Data processing enables governments to make choices based on large-scale analysis. Goals include allowances for greater policy transparency, and identification of high social and economic value. Most broadly, data mining aids decision-making through the discovery of patterns in large data sets based on facts or observations. Data mining tools can process structured numeric data in traditional databases or extract relevance from semi-structured and unstructured data, such as text, graphics, images, and web data. Leveraging Big Data can enable breakthroughs in e-Government management, where, like the many industries using Big Data to identify opportunities for innovation, governments are able to act on the best available information.

Big Data processing is not simply waiting for automatic results; it is necessary to master the tools and skills to transform raw data into information, knowledge, and wisdom. Skills and techniques to be mastered include data warehouse integration, business intelligence, and data visualization, as well as business analysis and forecast modeling. In addition, organizations must develop appropriate work processes and policies; find talent for drawing sound conclusions to meet ever-changing citizen needs[6-8].

E-government Model Based on Big Data

The e-government model based on big data can be established, as shown in Figure 1. Firstly, the big data from the government website, forum, social network, microblogging are collected, including the structured relational data and semi-structured and unstructured data. Secondly, the data source is extracted and integrated for the relationship and entity. After the relevance and polymerization, these data are stored with the structure with unified definition. When integrating and extracting the data, the data shall be cleaned to ensure the data quality and credibility. The finished big data are analyzed with the quantitative statistics, data mining and machine learning to used for the social population analysis, economic data analysis and other usages, and it can be submitted to the government user through the browser. The government can formulate the related policies according to the result of big data analysis.

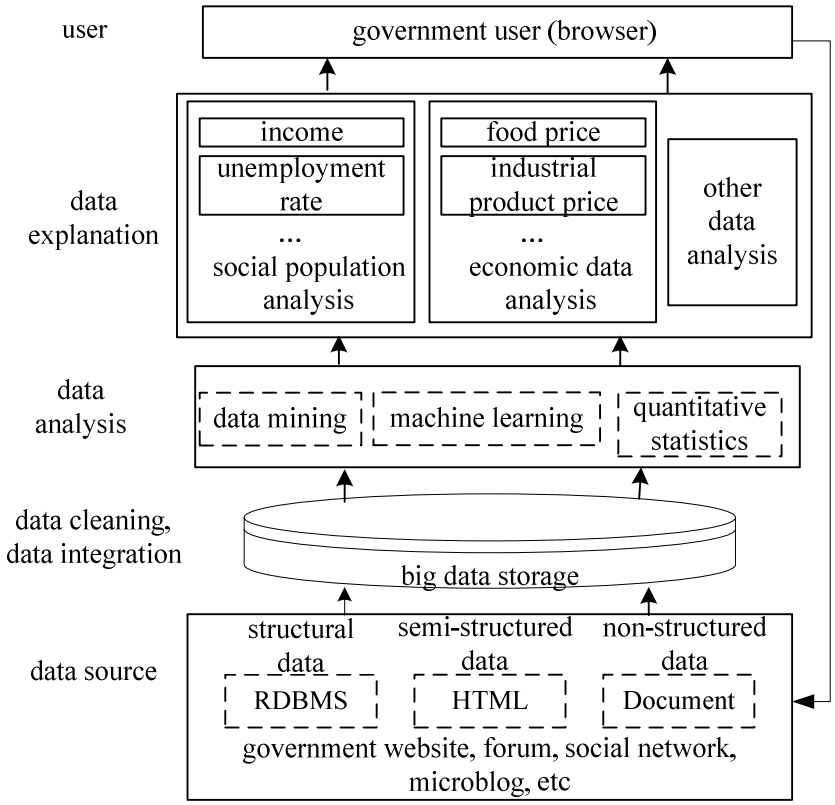

Figure1 E-government model based on big data

In summary, we must extract knowledge from massive data collections to build core capabilities in the development of e-Government services.

Internet Public Opinion Recognition and Tracking Based on Web Mining

Huailiang Shen, Feixia Bao

Zhejiang Business Technology Institute, Ningbo 315012, China

huailiang_shen@163.com

Keywords: internet public opinion, web mining, recognition, tracking.

Abstract. Recent years have observed the frequent occurrences of grave negative events. Along with the application and evolvement of Internet and new media, enthusiasms in distribution and discussing public opinion events have heightened. Internet public opinion research has thus become one of the research priorities of scholars in recent years. Internet public opinion research places heavy premium upon the emergence, evolvement, influencing factors and other aspects of public opinion. With rapid development and deepen evolution of internet public opinion in the internet, a variety of new methods occur on network. As the internet public opinion possesses the features of various topic, complex content and large amount data, the paper constructs an internet public opinion recognition and tracking based on web mining. Then the framework of the internet public opinion recognition and tracking system is presented. At last, it puts forward the whole workflow of the system to process the internet public opinion.

Introduction

The characteristics of the network public opinion has spread fast, wide audience, interactive ability, in the current political, economic, life has a great influence. Spontaneous, non rational and emotional characteristics of Internet users, the network public opinion and the rumor is difficult to distinguish, the authenticity of public opinion face huge challenges, become an important source of social instability. Therefore, to enhance the real-time monitoring of network public opinion, accurately grasp the impact of Internet public opinion trends and identification of public opinion, to give full play to the positive role of network public opinion in the social management and political democracy, has important significance.

Information society and network society further change the traditional values and social structure at the same time, also increased the instability and risk. Characteristics of various emergencies worldwide present normalization, diversified and systematic. Public crisis is no longer in society, and become the internal elements in the social structure. In the public crisis event occurrence, development and variation in the process, the network media and the internet groups active or randomly to the network as a platform, through the news, forum transmitted by means of information collection, analysis and exchange, forming a network of public opinion events or variation based on the characteristics of distributed, multiple etc. network public opinion has formed spontaneously storm, content complex of magnanimity and argument. The existing rigid intervention as the main means, in the traditional authority of the organization for the management level of passive response mode, it is difficult to adapt to the network supervision of the pressure, often in the management of a "one to many", "slow fast", "opposite" predicament. The dynamic and complex network environment information society puts forward new challenges to the emergency management of public opinion of the organizations at all levels, not only makes the information to transmit large range in a relatively short period of time, also broke the traditional government as the main body of the "single level" information communication control mode. How to realize the network public opinion effectively prevent and respond to emergencies in the multi polarization information communication mode of multimedia interactive participation, is a hot topic and a difficult problem in practice at present. In the transmission of emergency information and communication, various information trigger, coupling,

concurrent, conversion between the media presence, formed a reticular structure has a particular network topological properties between the emergency organization and individual.

According to the Internet public opinion main sources and distribution characteristics in the hot, information acquisition, information acquisition for the timeliness of the mainstream media websites and search engines, sources of information, high reliability, and good real-time performance, small amount of information collection, analysis and processing speed. Key words representative, simplicity, efficiency, information a large amount of Related words, correlation degree higher characteristic, to the maximum to minimum the amount of information covering the theme and intension of hot topic. This paper extraction as a hot topic tracking clues to the keywords, from the collection of the pages in the collection to extract a keyword set, and then taking these keywords clustering, is hot topic mining. Keyword based clustering to calculate minimum, high efficiency. To get the keywords set, the first keyword extraction of a single document set.

Web Mining

Web mining is not an unattended automatic discovering knowledge from the data of the algorithm, but is divided into a plurality of steps in the mining process. The workflow of the web mining is shown in figure 1.

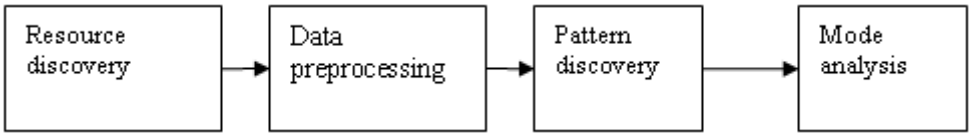

Figure 1 Web mining workflow

Resource discovery: needed to retrieve the text block, to obtain the required data from.

Data preprocessing: due to the local cache, proxy server, firewall, the Web log data are not precise, direct mining there may be erroneous results. Data cleaning is mainly whether the records, delete and algorithm independent judgment is an important access is not recorded; the user session is all a user request in a certain period of the web page; transaction identification is mainly the page should ask logic unit sequence as the representative of web transaction or user session.

Pattern discovery: pattern discovery is the use of statistics, machine learning methods such as mature technology, knowledge from Web usage mining. Method is found to be related with the electronic commerce mode with statistical analysis, cluster planning and dependency modeling. By using the statistical method, can choose the method to analyze the Webpage use characteristic, can analyze a character Webpage of click stream number, adjust the Webpage content and link structure according to the obtained results.

Analysis of the model: model analysis is mainly using appropriate techniques and tools, model analysis to assist the analysis understanding. Analysis of the most commonly used method is analyzed using the SQL query. Another analysis method is to import the data into multidimensional data cube, and then analysis and visualization of the results output by using the OLAP tool.

The Internet Public Opinion Recognition and Tracking Based on Web Mining

The network media information makes people in the acquisition of information often confused and meaningless, or to produce one generation, all Overgeneralization error. Network public opinion constantly, both published in well-known portal sites, famous newspaper website, also have somewhere deep in other forums, BBS and so on. Obviously, these tasks rely on limited manpower is not complete or not complete, objective. A desirable approach is: combining the data web crawler technology, mining technology, statistical theory and TDT technology together to complete, the automatic discovery and intelligent public opinion hotspot tracking process. The framework is shown in figure 2.

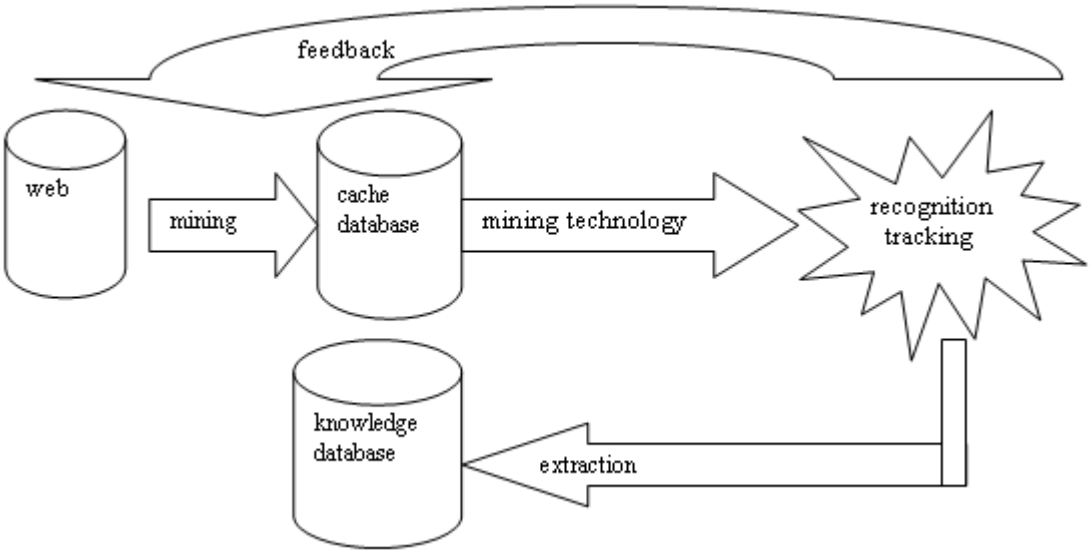

Figure 2 Internet public opinion recognition and tracking

Data preprocessing in Web mining

Pretreatment of Web using data is including data cleaning, session identification, page recognition and transaction identification. Because of the existence of the client cache and proxy server caching requirements, personalized service high need for improved path.

The use of Web data preprocessing, eventually get all page set appears in the transaction file and all user transaction set. All pages appear in the transaction file in the set P, where each page through its URL address uniquely identifies user transaction set T is expressed as T = {T1, T2,., TM}, transaction set in each transaction ti is a subset of the set P page. In order to facilitate subsequent data mining work (such as clustering), transaction set in each transaction t can convert to browse the n dimensional page space to quantity, i.e.:

t = < w (, t) , w (, t) , ··· , w (, t) >

(W, t) for t ∈ T weight affairs in page ∈ P

Many, a method to determine the weight size for example, if the transaction accesses the page, the weight is 1, otherwise the weight is 0 can also be a transaction in the browse page of retention time as its weight, which can be expressed on the transaction page interest degree. In order to deal with simple, using the above 0 - 1 weight representation methods.

The contents of Web data preprocessing includes from the text data and metadata extracting relevant features. If the page is based on the product page, or does not contain the text content, the page metadata extraction is very important. This paper mainly content extraction to the text content includes Meta tag contains XML or HTML and browse page. In order to calculate the similarity between different page content, content feature extraction must be given appropriate weight. The metadata, its weight is provided by the commercial website designers; the text features, its weight is widely used by information retrieval field term frequency inverse document frequency (TFIDF) decision, that is a particular word appeared on a page are of high frequency, while other pages appear in the frequency is very low, the words on the page of the weight is higher.

Content feature mining

In order to reference to recommendation engines, said method features should be and general use feature representation methods remain the same, also need to vector form. Unlike the general feature is, in the content feature mining, clustering process as far as possible will compare the contents of similar pages were clustered into the same cluster. Due to the same clustering browse page content is similar, but different user groups may be different part of the same page browsing interest, so the content features can reflect user overlapping interests and information needs

Page clustering is obtained by standard clustering algorithm is not suitable for representing the content characteristics. In order to use the characteristics and general representation consistent, can not be directly used to cluster web page clustering, but content feature extraction, data preprocessing

phase of browse page content feature matrix transpose, and every a content features can be regarded as browsing the n dimension vector space on the page, each dimension representing the content in the page weight. By clustering the clustering algorithm using a variety of standard features mentioned above, the result of clustering can be used in a clustering ensemble FC said, FC = { }, each content feature clustering CI consists of a series of content features

And the overall feature mining similar, need to browse page weight in the content features in CG are consistent processing, all the pages and filter out the significance threshold r weight less than specified

Given a feature clustering G and significant threshold R, the following methods to construct the content feature CG

$$C_G = \{ < p , \text{weight} (p , C_G) > | p \in P , \text{weight} (p , C_G \geq r \}.$$

Weight (P, P) for the page in the content feature weights, calculated as follows

$$\text{weight} (p , C_G) = \sum_{f \in G} \text{fw} (p , f) \Big/ \sum_{i=1}^{n} \sum_{f \in \theta} \text{fw} (p_i , f)$$

Summary

In this paper, we construct an internet public opinion recognition and tracking based on web mining. Then the framework of the internet public opinion recognition and tracking system is presented. At last, it puts forward the whole workflow of the system to process the internet public opinion.

Keywords: Cloud Storage; Relevant Failure; reliability; Replication Strategy

Abstract Cloud storage is an active research domain currently, and how to secure the reliability of data is an important research issue. For the moment, most systems apply the static data replication strategy, which causes a serious waste of storage resources. Considering the user requirements and the factors influenced on data reliability, i.e., the node reliability and Relevant Failure Degree, Data Replication Strategy based on Relevant Failure is provided in this paper. According to the results of the experiments, our strategy reduces the number of data replicas and meets the user requirement of reliability at the same time. Besides, the strategy has a better performance on increasing the utilization of storage resources.

Introduction

Cloud storage provides data storage and access service to the outside by collecting the different types of storage devices in the network through the clustered applications, the network technology, the distributed file system and so on. There are many companies have its own data storage systems, for example, Google File System[1], Hadoop Distributed File System[2] and Amazon S3.

An outstanding feature of Cloud storage system is that its underlying hardware facilities are constructed by inexpensive commerce servers. The system may be failure due to the interference of program, hard disk, memory, network, power supply and so on. These factors usually lead to the failure in two aspects, single-point failure and multi-point failure, i.e., Relevant Failure. Therefore, fault-tolerant technology is necessary in cloud storage. With duplication technology, it is recoverable by accessing the replicas of data resource when the data is failed or lost. However, duplication technology also results in serious dissipation of storage resources while improving fault tolerance of the system. GFS adopt a typical 3-replicas data replication strategy by default, i.e. store 3 data copies at one time, to meet the requirement of data reliability. Literature [3] proposed a novel dynamic data replication strategy which facilitates an incremental replication method to reduce the storage cost, but this strategy only consider the reliability of node without considering the effects of the relevant failure between nodes.

To tackle this issue, in this paper we propose an effective dynamic data replication strategy named Data Redundancy Replication (DRR). According to the results of the experiments, DRR can reduce the number of data replicas and meet the user requirement of reliability at the same time. Besides, the strategy has a better performance on increasing the utilization of storage resources.

Cloud Storage Environment Modeling

In this subsection, we model cloud storage environment and formalize it as follow.

Definition 1. The cloud storage environment is defined as a collection of many storage nodes, and it can be represented as the following formula:

$$Storage_System = \bigcup_{i=1,2,3,\ldots,m} \{n_i\} \quad (1)$$

where n_i is the number of the node i.

Definition 2. Relevant Failure Degree is defined as the possibility of relevance failure between two storage nodes, denoted by σ. All of relevance failure degrees can be represented as a matrix:

$$Relevance = \begin{bmatrix} 0 & \sigma_{12} & \sigma_{13} & \dots & \sigma_{1m} \\ \sigma_{21} & 0 & \sigma_{23} & \dots & \sigma_{2m} \\ \sigma_{31} & \sigma_{32} & 0 & \dots & \dots \\ \dots & \dots & \dots & 0 & \sigma_{(m-1)m} \\ \sigma_{m1} & \sigma_{m2} & \dots & \sigma_{m(m-1)} & 0 \end{bmatrix}$$

where σ_{ij} is the possibility of the node n_i and n_j are failure simultaneously. For each $i, j \in \{1,..,m\}$, we can conclude that:

1) $\sigma_{ij} = \sigma_{ji}$, if $i=j$, then $\sigma_{ij}=0$;

2) The bigger σ_{ij}, the weaker the relevance between n_i and n_j, and vice versa.

Definition 3. $\forall i, j = 1,2,3,\ldots,m$ and $i \neq j$, the distance between n_i and n_j is S+1, where S is the number of network switching devices from n_i to n_j. We represent the distance as the following matrix:

$$Distance = \begin{bmatrix} & d_{12} & d_{13} & \dots & d_{1m} \\ d_{21} & & d_{23} & \dots & d_{2m} \\ d_{31} & d_{32} & & \dots & \dots \\ \dots & \dots & \dots & & d_{(m-1)m} \\ d_{m1} & d_{m2} & \dots & d_{m(m-1)} & \end{bmatrix}$$

Definiton 4. $\forall i, j = 1,2,3,\ldots,\mathrm{m}$ and $i \neq j$, the Relevance Failure Degree σ_{ij} between n_i and n_j is represented as:

$$\sigma_{ij} = \frac{1}{d_{ij}} \tag{2}$$

Reliability Modeling

Tian[4] proposed a method for calculating the failure rate based on Weibull(scale, shape) distribution:

$$\lambda(t) = \left[\frac{shape}{scale}\right] \times \left[\frac{t}{scale}\right]^{shape-1} \tag{3}$$

where scale is the lifetime parameter, which measures the average life of the node.

Definition 5. $\forall i, j = 1,2,3,\ldots,\mathrm{m}$, the reliability of node is represented as:

$$R(n_i) = 1 - \lambda(t_i) \tag{4}$$

where t_i is the run time of node i.

Definition 6. Assume that data is randomly saved in the set of nodes $\bigcup_{i=1,2,3,\ldots,m} \{n_i\}$. The reliability of node $R(n_i)$ and the relevance failure matrix Relevance are given, then the reliability of data can be defined as follow:

$$\theta = \begin{cases} R(n_1), k = 1, \\ 1 - (1 - R(n_1)) \times \prod_{i=2}^{k} \left[1 - \frac{1}{i-1} \sum_{j=1}^{i-1} \left(\frac{1}{1+\sigma_{ij}}\right) \times R(n_i) \right], k > 1 \end{cases} \tag{5}$$

Where k is the number of replicas.

Data Redundancy Replication（DRR）Strategy based on the Associated Failure

The idea of DRR is to use the minimum number of replicas while meeting the data reliability requirement. By solving data reliability function (3), (4), (5) separately, the reliability of the data can be determined, which indicate when the current number of replicas cannot meet the user requirement any longer and a new replica should be created.

The pseudo code of DR is shown in Figure 1.：

Algorithm Data_Copy_Strategy(C_need, $\bigcup_{i=1,2,3,...,m}\{n_i\}$)

{//input：user requirement and the set of storage nodes

//output：the number of data replica

① n_{chose} = rand（ $\bigcup_{i=1,2,3,...,m}\{n_i\}$ ）；//chose one node n_{chose} in $\bigcup_{i=1,2,3,...,m}\{n_i\}$

②Chose_Set= Ø

③k←0;

④k=k+1；

⑤Chose_Set=Chose_Set∪ $\{n_{chose}\}$；

⑥Data_Reliability (Chose_Set , θ)； // solve the function of data reliability

⑦if($\theta \geq C_need$) then return k；

⑧else loop ①//create one more replica for the data if current data reliability is lower than

Fig 1. The pseudo code of DR strategy

Experimental Evaluation

This paper simulates a cloud platform through building a trilaminar network switch model of twelve storage nodes. The model is shown in Figure 2. With the platform, we made a test on the data replication strategy proposed by this paper.

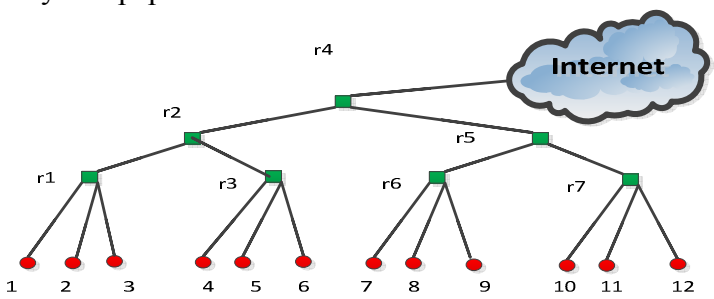

Fig 2. The simulation platform

Under the model, a relevance failure matrix Relevance is created, $\sigma_{1,2}$=1/2 , $\sigma_{1,4}$=1/4 , $\sigma_{1,7}$=1/6 ...

A parameter value of shape in formula (3) is assigned by a value of [0.7, 0.8] at random when nodes start to run. After a period of one day, the shape is fixed by a value of [2, 3] randomly[4]. We set the value of scale 120 based on the research to Google cluster[5].

Reliability of storage data, represented by parameter C_need, can be set by users. It is based on an analysis of many users that while the value of C_need is 99.00%, it is sufficient to meet the need of reliability of a majority of users. So we make C_need not less than 0.99, and C_ need ∈ {0.99, 0.999, 0.9999} in this paper.

Assume that all storage nodes are isostructural and launch simultaneously, so they have identical failure rates at the same time. At different time points, extract several users at random and combine the users with different storage nodes randomly. By the data replication strategy proposed by this paper, figure out the number of redundancy storage without losing user demands. A portion of experimental results is listed in Table 1.

Table 1. The Experimental Results

Customer	C_need	T/[day]	Data Reliability	The number of replicas
1	0.99	0.1	0.9939	2
2	0.999	2.5	0.9999	1
3	0.99	10.8	0.9998	1
4	0.999	10.8	0.9999	2
5	0.99	34.2	0.9996	2
6	0.99	65.4	0.9926	1
7	0.999	80.0	0.9994	3
8	0.99	80.0	0.9977	2
9	0.999	95.9	0.9996	2
10	0.9999	118.7	0.9999	3

From the result of Table 1, we can claim that only 1*3+2*5+3*2=19 storage cells are needed in our strategy but 10*3=30 storage cells in a typical 3-replica strategy. The simulation shows that our data replication strategy for reliability can significantly reduce the number of replicas.

Conclusions

This paper presents a data redundancy replication strategy based on relevant failure. The strategy takes into account the user requirements and the factors influenced on data reliability, i.e., the node reliability and Relevant Failure Degree. Experiments show that the strategy can improve the utilization of storage resources while meeting user requirement of reliability. However, there are still some works not well studied in this paper. First, how to model the storage node failure process is very critical for the implement of DRR in real system. Second, when choosing the storage node, we do not consider the load balance between the nodes. These issues will be done in the near future.

Keywords: Oracle Synchronization; Timing; Export; Import

Abstract. In the practical application of developmental internet, often synchronizing Oracle database tables, the establishment of a reliable remote database synchronization scheme is necessary. The paper uses the EXP/IMP logical backup tool of oracle, tuning of EXP/IMP, and combined with shell command, to implement a remote database synchronization scheme. In addition, this program implements the timing of the Oracle database synchronization.

Introduction

EXP/IMP is a logical backup tool provided by Oracle and a logical backup start to work in case of the database is started. The essence of exporting is reading a set of database record (even it's a data dictionary) and write the record to a file. There is no relation between exporting the records and their physical location. The essence of importing is reading the dump file and executing the commands. This approach is backed by Oracle's export and import utilities to implement. 'Export' is to export the data, and 'import' is to import the uninstalled data, exported by 'export', into the database. This tool can be derived from a variety of functions, for instance, the whole database backup, table structure reconstruction, data transmission, etc.

Oracle Export/Import tools provide a flexible functionality and export/import models, the three most commonly used mode is User, table and full Database. In addition, the tools can decide to export/import whether the object contains information about the data dictionary, for instance, index, constraints, authority etc. However, using EXP/IMP has a flaw. Using the Export tool is a logical backup of the database, which can only be used in logical data. If the database is physically damaged, leading to not start, logical backup data does not help to restore the database.

Export and Import of key technologies

The key technologies of Export and Import.The Oracle exp command is used to implement the export operation on the database. This command import dmp files to local Oracle server. Three kinds of importing table modes: table recovery, user recovery, complete recovery.

1.1 Exporting table mode

Backup mode specified under a user object (table). Business databases often use this backup method. If backing up to a local file, use the following command:

exp myName/myPassword rows=y indexes=n compress=n buffer=65536 feedback=100000 volsi ze=0 file=exp.dmp log=exp.log tables=tab1,tab2,tab3

1.2 **User mode**

Backup all objects under a user mode. Business databases often use this backup method. If backing up to a local file, use the following command:

Exp myName/myPassword owner=youWantOutUser rows=y indexes=n compress=n buffer=65536 feedback=100000 file=exp.dmp log=exp.log

1.3 **Complete mode**

Backup the entire database. A business database doesn't use this backup method. The command of backup: exp myName/myPassword rows=y indexes=n compress=n buffer=65536 feedback=100000 full=y file=exp_.dmp log=exp.log

Three modes of importing and exporting are identical. The only difference is changing EXP to IMP.

Achieve timing backup software

2.1 **the flow chart of software design**

Flow chart of the software as shown in Figure 1.

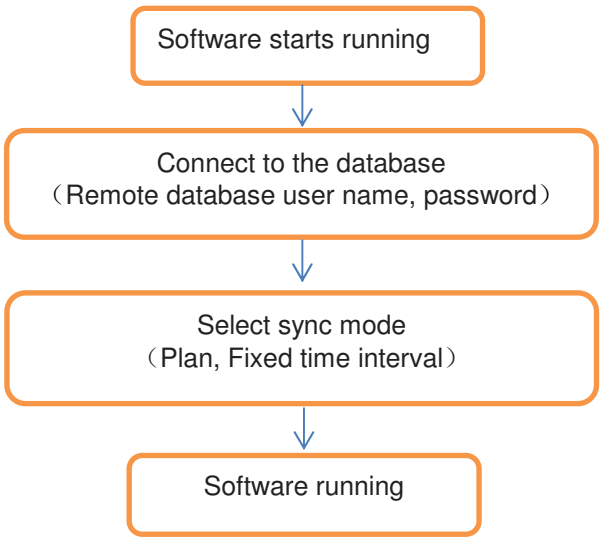

Fig.1 Software process design

2.2 **Oracle timing synchronization interface and operation**

The Microsoft Foundation Class Library (also Microsoft Foundation Classes or MFC) is a library that wraps portions of the Windows API in C++ classes, including functionality that enables them to use a default application framework. Classes are defined for many of the handle-managed Windows objects and also for predefined windows and common controls.

The software using MFC Library. The software interface shown in Figure 2.

The key code is as follows:

Key backup code： exp myname/mypassword@192.168.100.152/orcl file = d:\my.dmp tables=(test1,test2);

Key synchronization code：imp myname/mypassword@192.168.100.152/orcl file = d:\my.dmp tables=(test1) ;

Set the timer：Creates a timer with the specified time-out value.

```
UINT_PTR WINAPI SetTimer(
  _In_opt_  HWND hWnd,
  _In_      UINT_PTR nIDEvent,
  _In_      UINT uElapse,
  _In_opt_  TIMERPROC lpTimerFunc
);
```

The specific operation as follows:

(1) Fill the database connection information, and test the connection.

(2) Select the synchronous mode. There are three ways to synchronize the situation: You can choose to perform once; Can be synchronized according to plan；Can be synchronized at fixed intervals.

(3) Determine and run the software.

Summary

To prevent data loss caused by a failure, which cannot be recovered, backup the data. How to reduce the complexity of database management. Establishing a Centralized, online, real-time synchronization system has a very important significance. This paper describes the strategy of timing backup Oracle database, after a lot of practical application, for improving efficiency in the use of the Oracle database synchronization has a great role and certain advantages in the security, economy and reliability.

Keywords: Time Context; User Behavior; Clustering

Abstract. Analysis of user behavior management control has important significance for network users. This paper uses the clustering algorithm to cluster the user behavior for clicking certain software or Website in different times, through the time context of user behavior to analyze user behavior rules. Additionally, this paper analyzes the clustering result in detail, then, divides user behavior into different types. Finally, according to the clustering result, more targeted pages and applications are recommended to the network users to create huge business value.

Introduction

With the rapid increase of network users, how to utilize the rich contextual information and user behavior information to obtain the user's preferences, to provide users with personalized services, is an important issue each Website needs to focus on currently.

Context is the description of environment related information, the information can be any kind of environmental information related to a user or device, including time, place, people around, emotions and etc. This paper is to analyze network user behavior patterns based on the time context, namely according to the records of accessing various Websites every day, knows what users, in what time, do what things, and do how many times, then, the user's behavior patterns can be applied to many scenarios. For example, personalized Website display according to different user behavior patterns, user behavior patterns can also assist e-commerce sites to do market segmentation. Furthermore, user behavior pattern can also help advertising push, according to their behavior in a particular time to push the corresponding advertising.

Data sources and pretreatment

The data used in this paper is provided by the CNNIC which provides 5000 randomly selected sample users. The data includes the behavior log these users access to the software and Website in 4 weeks, and the corresponding sample population attribute information. A log file is created every time a sample user turns on the computer. The first 2 lines in the log file record the following 2 values:

Last: the number of seconds when the last updated time of log subtracts the boot time. L_Start: The boot time of sample user (Year-Month-Day Hour-Minute-Second)

Next, the data collection procedures will scan the focus window on sample users' computer in a frequency of 2 seconds. If the focus window changes, a new record will be appended into the log file. See Figure 1 for the appended record information.

According to the sample data statistics, the computers of these 5000 users are turned on about 20% of the time in 28 days on average (about 5 hours a day). These data records an important part of entertainment and work in daily life for each user, so the user behavior patterns mining is very meaningful. The purpose of this article is to observe the behavior of each user every day, that is the user does what things in what time. For example, a user spent half time to deal with business related work on computer and the other half time on entertainment in the morning. Then, the user behavior can be included into "work and play" in the morning.

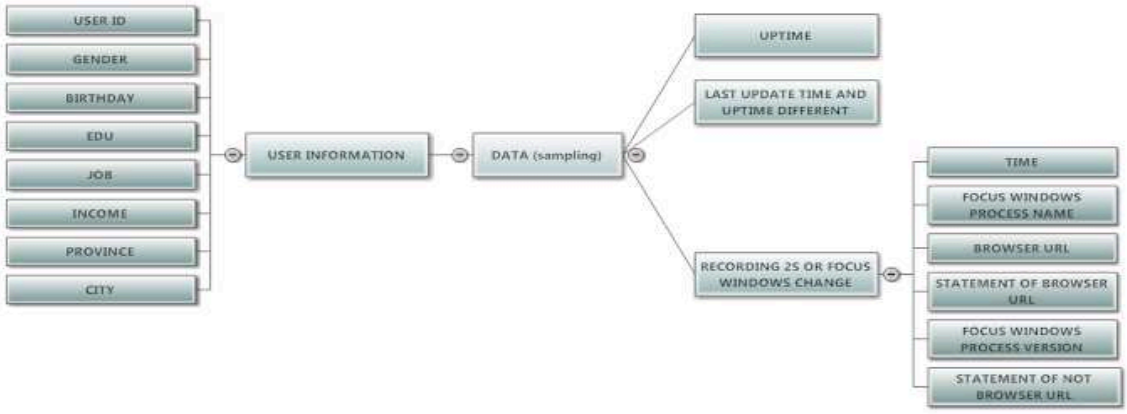

Figure 1 Data collection for sample user

Specific data processing architecture as shown in figure 2. First of all, pre-treat the data, then, import data to the Sql Server to generate the required reports and intermediate data, and then labels the data to generate the correct file format required by the following data mining. This article uses weka as the analysis engine generates the required schema information, and use mahout for data mining, then, generate the final behavior classification mode.

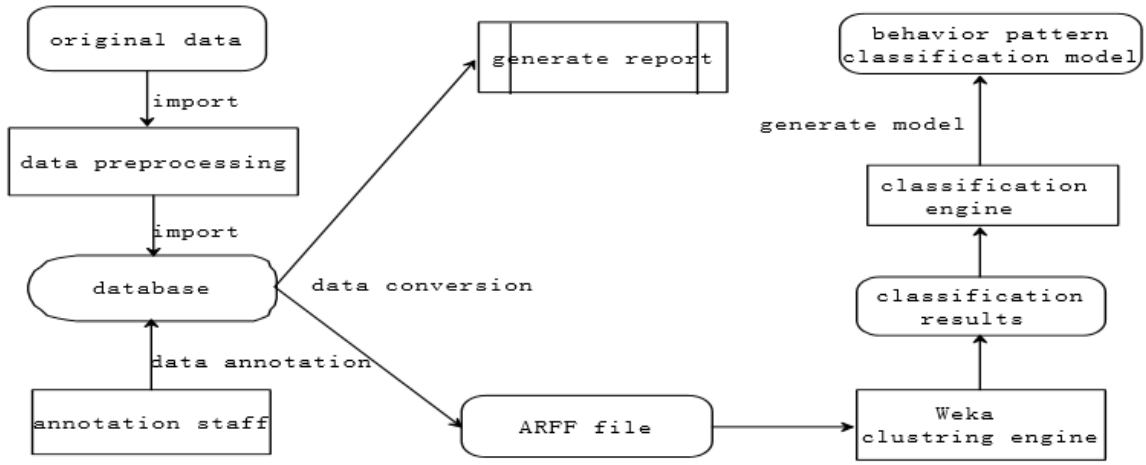

Figure 2 Data Processing Architecture

K-means clustering technology

Clustering analysis is to divide a set of objects into clusters, similarity degree is high within the cluster, while similarity degree is low between the clusters. Clustering is an unsupervised learning, namely, the division is reasonable according to the respective characteristics of the objects, no model for reference or to follow. Clustering analysis is an important technology in data mining, and are widely used in every field of the database. In 1967, McQueen proposed k-means clustering algorithm, the algorithm is described below[2][3]:

Input: Dataset D which contains n objects and cluster numbers K

Output: Collection of K clusters.

Steps:

(1) Choose K objects from the dataset D as initial center of K clusters.

(2) Repeat.

(3) Categorize each object to similar cluster according to the average value of the objects in the cluster

(4) Re-calculate the average value of cluster.

(5) Until the average value of cluster does not change.

The algorithm complexity is 0 (NKT), n represents the total number of objects, k represents the number of clusters, t represents the number of iterations.

Data Processing

1 Data Label

Firstly, turn on the related data labeling process, extract most common 1000 software and 1000 URLs out of the existing data behavior log, and then label these software and Website URL. For more information, see table 1 and table 2. From the following tables, we can see, in the process of software use, the proportion of chat, games, and the working software is relatively high. In the URL visit, the proportion of news, social, and shopping sites is relatively heavy.

2 Data Feature Extraction

According to the characteristics of the data label, we divide software and Website into three categories: work related software, life related software and entertainment software. Additionally, user access time is divided into morning and afternoon, and measurement choice is the frequency ratio a user in a certain period of time access to certain Websites or software. Then, we give each user a feature vector to his every day statistical behavior by use this data modeling, and then cluster these eigenvectors. For more information, see Table 3 and Table 4.

Table 3 Clustering Statistic

Clustering Goal	Statistic user each day behavior
Time Division	morning & afternoon
Behavior Categeory	Work, life, entertainment
Characteristic value choice	Clicking frequency for different software or Website

Table 4 User Behavior Statistic

ID	Morning Work	Morning Life	Morning Entertainment	Afternoon Work	Afternoon Life	Afternoon Entertainment
User A 08/01	30	21	24	12	3	10
User B 08/01	11	12	75	0	0	3
User A 08/02	5	3	41	4	3	44
……	……	……	……	……	……	……

According to the clustering analysis and calculation, the user behavior is divided into five categories, respectively class 0, class 1, class 2, class 3 and class 4, specific data for each class is shown in Table 5.

The characteristics of users in Class 0 is using computer for a long time every day for work, life, and entertainment. These users are highly dependent on computer;

The characteristics of users in Class 1 mainly use computer for work and entertainment for a long time every day. While, their life rarely uses the computer. These users are highly dependent on computer for the work and entertainment;

The characteristics of users in Class 2 mainly use the computer to work and play for appropriate time, they use more in the afternoon. These users belong to modest dependence of the computer user group;

The characteristics of users in Class 3 mainly using the computer to work and play for moderate time, they use more in the morning. These users belong to the morning play computer users group;

The characteristics of users in Class 4 mainly using the computer to entertainment for a short time, , they use more in the afternoon. These users belong to play for a while computer user group.

Table 5 User Behavior Clustering Category Table

Cate-gory ID	Morning Work	Morning Life	Morning Entertainment	Afternoon Work	Afternoon Life	Afternoon Entertainment	Category Proportion
0	57.3	152.8	128.4	58.5	148.8	147.0	9%
1	95.4	19.0	178.2	94.8	10.6	201.6	12%
2	0.1	0.0	10.0	3.2	1.3	52.2	31%
3	10.9	2.4	41.3	29.2	20.1	114.1	26%
4	20.5	12.0	95.5	0.8	0.0	11.4	22%

According to the category classification and statistics, we can get the user behavior model, as shown in Figure 3.

According to the proportion of categories and user behavior model, we can see that, 9% of the behavior belongs to the class 0, the characteristic of this kind of behavior is active both in the morning and afternoon, while life or entertainment occupies more time in the morning, such users extremely dependent on computer.

12% of the behavior belongs to class 1, the characteristic of this kind of behavior is more active in the morning, and proportion of visiting working class software or Website is high.31% of the behavior belongs to class 2, the characteristic of this kind of behavior is the proportion of morning & afternoon software visit is balanced, and most of the time is on a visit to the entertainment related software.

The characteristic of Class 3 behavior is active in the morning, and most of the time is on a visit to the entertainment related software.

The characteristic of Class 4 behavior is only active in the afternoon, the main content of the activity is for fun.

According to this clustering of category, the effect from homogeneous degree and the interpretability of each class is very good.

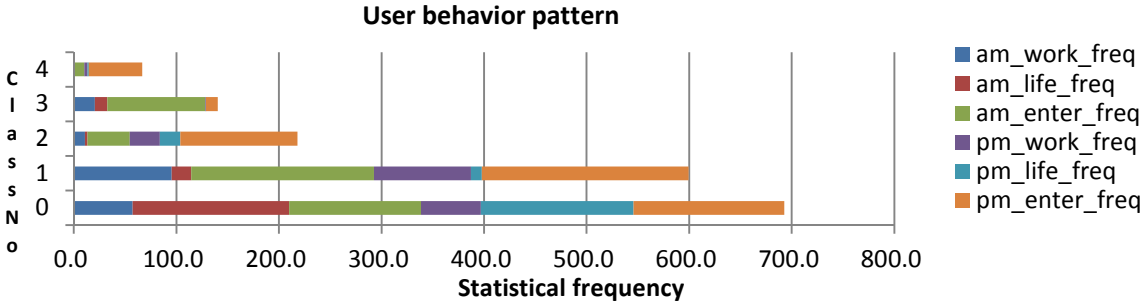

Figure 3 Each Day User Behavior Schema

According to the clustering results, it can be predicted to each user behavior, then, calculate the user behavior category. In order to verify the user behavior prediction accuracy, the author respectively cluster the user behavior for four weeks with the same time period, behavior category and characteristic value as daily behavior. Figure 4 get user behavior model for four weeks through clustering classification.

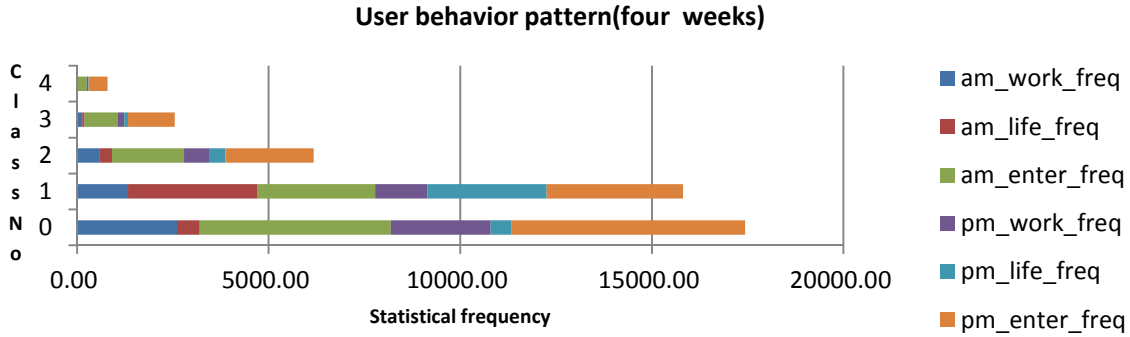

Figure 4 Four weeks User Behavior Schema

Through all the eigenvalues of users on a daily basis to forecast classification, the result accuracy was 97.58%, using user behavior patterns for four weeks to predict classification, the result accuracy was 91.54%, the daily prediction accuracy is higher than four weeks behavior prediction accuracy.

In order to verify the accuracy, we predict behavior model through the user basic, its accuracy is only 26.81%. However, predict the user daily behavior characteristic of the accuracy is 67.52%. Meanwhile, predict the user four week behavior characteristic of the accuracy is 62.40%.

To prove the result of the experiment is not accidental, the author conducted a series of eight experiments. Firstly, we divide clustering goals into two kinds, namely daily the user statistic behavior and four week user behavior. In time aspect, in addition to adopt the way of dividing morning & afternoon, also adopted the way of the division of work and non-work time. Through

experiments, the result accuracy is over 95%, the average is 97.53% for users all the daily eigenvalues prediction classification. And result accuracy is over 80%, the average is 89.58% for four week prediction. The experimental data shows that the accuracy of user behavior prediction is rather high.

Conclusion

In this experiment, according to the different clustering goals, different ways of time division, the different approach to deal with eigenvalues, different clustering algorithm parameters, we get a total of 16 groups of experimental results. The clustering result is clear and easy to explain.

Use all user behavior information proves the rationality of the classification, the accuracy is between 85% and 100%. Additionally, use part of the user behavior information to predict the user's behavior model is feasible and accuracy between 50% and 70%. However, it cannot correctly predict the user's behavior pattern only from the user basic information (age, education, geographic area), because the accuracy is only between 10% and 30%. By the experimental results, we can also see that daily statistics action as target clustering is superior to the four week statistical behavior as clustering around the target.

Therefore, it has great research significance and application value to apply predicted user behavior model to a variety of situations through time context user behavior patterns prediction model, to provide information, personalized service and etc.

Keywords: Minimum Vertex-Cover Problem; Computational Complexity; Solution Space Organization

Abstract. We focus the solution space of a most fundamental problem - Minimum Vertex-Cover problem - in theoretical computer science. After some rigorous analysis, we provide the formation mechanism of minimum vertex-cover solutions on the tree and give the organization of these solutions on arbitrary lattice structure. By the results, we can easily calculate the solution numbers on these structures and have better understanding of the hardness of Minimum Vertex-Cover problem. The proposed study and algorithm can make a new way on detecting the essential difficulty of NP-complete problems and designing efficient algorithms on solving them.

Introduction

Minimum Vertex-Cover problem is one of the most important NP-complete problems [1], which has wide applications in immunization strategies in networks [2] and monitoring of internet traffic [3]. As a basic problem in mathematics and theoretical computer science, how to understand the complexity of solving Minimum Vertex-Cover is a hot topic attracting many attentions from mathematicians, physicists and computer scientists.

The computational complexity of Minimum Vertex-Cover problem is attributed to the complicated organization of it solution space, especially some structures, such as frozen nodes [4], mutual-determinations [5] and clustering [6]. Unfortunately, few rigorous results on the structures are obtained and most analysis is based on some empirical assumptions. In the viewpoint of computational complexity, the corresponding analysis of these structures belongs to the #P class [7], the complexity of which is considered much harder than that of NP-complete.

As a simple case, we can easily find a solution of Minimum Vertex-Cover when the given graph is a tree or a forest. Besides, for the graphs with no leaf-removal core, finding a minimum vertex-cover can also be finished in polynomial time complexity [8]. However, when the graph becomes denser with hard core after the leaf-removal, solving the minimum vertex-cover generally needs exponential time complexity [8].

In this paper, we focus on the Minimum Vertex-Cover solutions of trees and lattices, and make analysis on finding different solutions of them. Besides, based on the organization of different solutions, we study the information dissemination process on the nodes by vertex-cover and give strategy on calculating the solution numbers. The investigation of the information dissemination on the minimum vertex-covers will provide scientific directions on solving the NP-complete problems and help make further understanding on their solution space structures.

The minimum vertex-covers on a tree

A vertex-cover on an undirected graph G(V,E) with the node set V and the edge set E is a subset S = {i1,i2, . . . ,ik} of its nodes such that every edge has at least one end node in S. The Minimum Vertex-Cover problem is an optimization problem to find the minimum size of a vertex-cover on a given graph.

In mathematics, and more specifically in graph theory, a tree is an undirected graph in which any two nodes are connected by exactly one simple path.

If the graph is just a tree, the leaf removal [9] should be mentioned .Given a graph G, a leaf is a couple of nodes {v, w} in which the first one has degree 1 and the second one is the only neighbor of it. Here, node v is a pendant node in the graph, node w acts as a petiole, and for the same petiole there may be more than one pendant nodes connecting it. For each leaf has at least one node to be covered, we can set the petiole nodes covered. To define the leaf removal, if the nodes pair {v, w} is a leaf in graph G, remove the two nodes with the edges touching them. It is very interesting that the leaf removal process can destroy all the leaves in graph G and can produce new leaves for the rest of the graph. By this process, the following facts can be determined: a) covering a petiole provides a local optimum; b) The tree can be solved by step by step leaf removal process; c) the local optimum can help to obtain the global optimum. Evidently, covering all the petioles on a tree can obtain a minimum vertex-cover. In FIG.1, the process of obtaining minimum vertex-cover by leaf removal for a simple graph is shown.

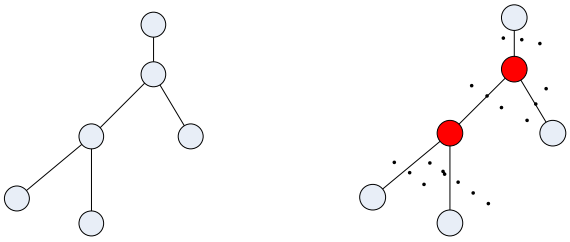

FIG.1 A simple graph with two leaves and two petioles covered

Obviously, we get a minimum vertex-cover of the tree, and also get the size |Vc| of it. Based on it, we can extend this rigorous result and find all the minimum vertex-cover, and provide strategy on calculating the total number of all the minimum vertex-cover solutions of a tree. The whole process of leaf removal can be seen as an information dissemination process from the leaves to the roots. When a node is determined to be uncovered, it will force its adjacent nodes to be covered. There is no effect of information dissemination to the neighborhood of the covered nodes. Besides, it is an important fact that the petiole must be covered when there are more than one pendant nodes in the leaf.

So, if a tree is concerned to calculate the number of all its minimum vertex-cover solutions, we can find its solution space by a branch-and-bound algorithm in the following:

We can treat the tree as a series of leaves in the viewpoint of leaf-removal process:

a) If the current petiole is connected with more than one pendant, cover it and delete the leaf with edges connected to it. Result a sub-graph.

b) If the current petiole only has one pendant, the two nodes can be covered either, so

1) Cover the petiole, and delete the leaf with edges connected to it. Result a sub-graph.

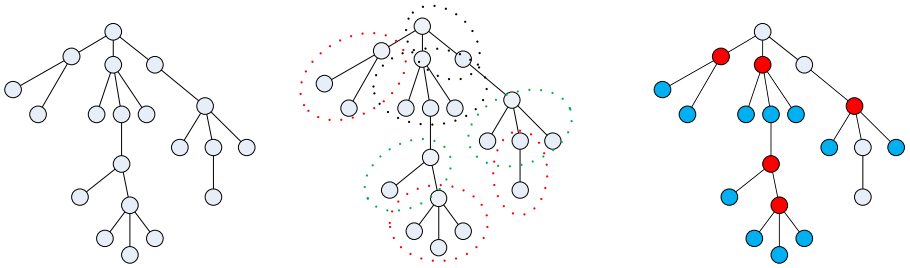
2) Cover the pendant, and consider the information dissemination process. Result a sub-graph.

3) Add up the number of solutions in the above two cases.

c) For the sub-graphs obtained, repeat step a)-b) until there is no leaf left.

b) The total number of all its minimum vertex-cover solutions is obtained.

Evidently, the above algorithmic strategy is polynomial in computational complexity. In FIG.2, a simple example is shown. Its number of minimum vertex-cover solutions is four, and the minimum vertex-cover has seven nodes.



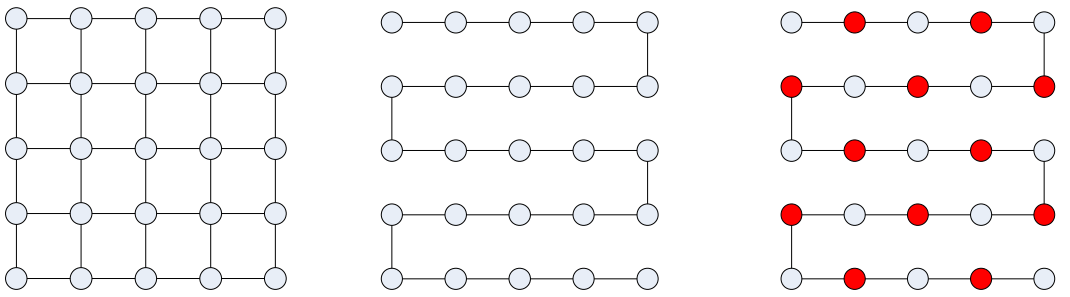
Original tree graph different leaves on the tree resulted graph

Fig.2 An example for the branch-and-bound algorithm: the red nodes must be covered in the minimum vertex-cover, the blue nodes must be uncovered and the rest two white leaves are free to cover the petiole or the pendant

The minimum vertex-covers on a lattice

Lattice is a graph that can be drawn within a repeating arrangement of nodes. Typically, no clear distinction is made between such a graph in the more abstract sense of graph theory and its drawing in plane or 3D space.

In the plane lattice, we divide the node set into two distinct subsets M, N by the diagonal relationship. For example, in a lattice G, we use (i, j) to mark each node, $M = \{(i, j) \mid i + j = 2n, n \in N+\}$, $N = \{(i , j) \mid i + j = 2n +1, n \in N+\}$. The nodes in set M only connect the nodes in set N, and so do the nodes in N. In left graph of FIG.3, we have $|M| = 13$ and $|N| = 12$ in lattice G, and based on this partition, covering all the nodes of N can obtain a vertex-cover of G. Similarly, M can also form a vertex-cover of G, but the scale of N is smaller. Obviously, the coverage of nodes in N is a minimum vertex-cover of G. To prove it, we delete some edges of the lattice to obtain a sub-graph G', which is shown in the middle graph FIG.3. The structure of G' is very simple, it is one-dimensional. In this figure, it is clear that M, N are both vertex-covers of G'. According to leaf removal algorithm [9], N is the minimum coverage of G' and is the only coverage, which is shown in the right graph of FIG.3. As is known to all, if the only minimum vertex-cover of sub-graph G' can still cover graph G, it is also the minimum vertex-cover of G.



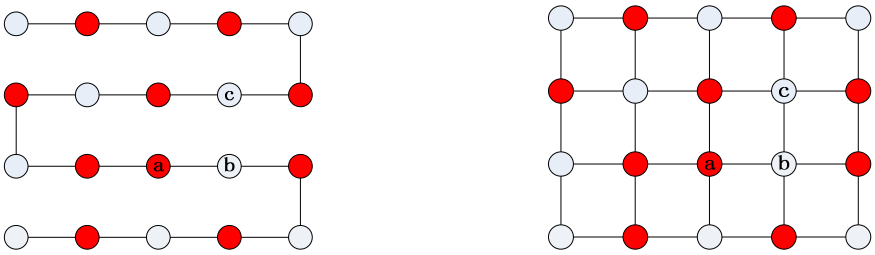
G *G'* minimum vertex-cover *N*

FIG.3 An example to calculate the minimum vertex-cover of plane lattice

Thus, we get a conclusion on the plane lattice that if the sizes of set M and set N are not equal, the set with smaller size will be the only minimum vertex-cover of plane lattice G.

If the partitions M, N have the same size, then the sub-graph G' has several minimum vertex-cover including M, N. As a special case, the node sets M, N are certainly minimum vertex-covers. However, the above analysis process in figure may lead to mistakes. For example, in the following G1' of FIG.4, the red dots are shown as the coverage S. Obviously it is a solution of the minimum vertex-cover of graph G1'. We can see that in the middle of this one-dimensional lattice, the coverage strategy is changed, in which node a is covered and b is not. In graph G1, the nodes b, c are connected and this edge is not covered by S, i.e., S is not a vertex-cover of the original graph. Then, minimum vertex-covers of the sub-graph G1', except M and N, cannot be

easily generalized to minimum vertex-covers of the original graph G1. After simple deduction, we can get the second conclusion: when the partitions of M, N have the same size, M, N are the only two minimum vertex-cover solutions of G1.



G_1' with coverage S G_1 with S

FIG.4 An example to verify the invalidity of the analysis process in FIG.1

In summary, if G is a lattice with 2n +1 nodes, the minimum vertex-cover of G has one and only one solution N, and the size of N is n; If there are 2n nodes in G, then the minimum vertex-cover solution space of G is {M, N}, where the size of M or N is n. All the above conclusions can be extended to high dimensional lattices.

Conclusion

Some basic characteristics of the minimum vertex-covers on the lattice and tree structures are investigated in this paper, and rigorous results or algorithm are proposed on calculating the solution numbers. Certainly, all these two cases belong to the easy-solving case in Minimum Vertex-Cover Problem, and how to generalize the idea to solving other complicated cases, such as random graphs [10] or scale-free graphs [11], is still quite difficult. We hope more efficient algorithms can be proposed based on the results in this paper, and it will be an interesting research direction.

Abstract. Changes in the development of computing technology and calculation model of a profound impact on the development of human society, the popularity of networks and portable devices today and in the future, desktop computing mode has not been able to adapt to the changes in the development of the computer man-machine relationship changes and user computer method. Pervasive computing is in this context is proposed. The new model emphasizes the computer into people's daily life and working environment, to form a "at any time, everywhere and invisible" computing environment. In such a computing environment, user can calculate the services and information resources through the handheld, wearable devices used or other conventional, unconventional computing devices without obstacles. The innovation from the desktop computing to ubiquitous computing can be seen, human-computer interaction is an important index for pervasive computing.

Introduction

Pervasive computing refers to the ubiquitous, anytime, anywhere can be a way of computing. Users in this computing environment, wherever and whenever. As long as necessary, you can have access to the information the90s, Dr. Weiser United States proposed "ubiquitous computing" This new concept began to future human exploration of the process of the computer age [1] In the era of ubiquitous computing, there will be a lot of computing devices with computing and networking capabilities will provide services for us, a wide variety of computing devices are embedded in the walls, chairs, clothing, light switches, etc. all things automotive. Everything has the computing power of the devic y need by some devices. The present era, the computer has been entered in all areas of human life. The actual status of the computer in people's daily life, had earlier is no longer a simple tool for human use. With the advent of the development of computer-related technology, communications technology and a variety of new sensors, computer equipment to access the Internet, people more insight into the calculations everywhere. The early 19e will be fully utilized, making today's expensive "thin client" while a "thin server." An important sign of pervasive computing is a natural and efficient human-computer interaction. In recent decades, with the rapid development of computers, human-computer interaction has also undergone a major change, we can say history is the history of the development of the man-machine interface of a computer. From the initial input to the panel switches and tape devices to interact characterized today's graphical user interface, HMI has undergone enormous changes.

Many people through road desk alternately technology background

Research on human-computer interaction technology is a problem when people use the computer to complete a task, the mutual exchange of information between the computer and the ways and means. Can abstract a dialogue between human and computer-level interface, called interactive interface. It is an important part of a computer system, through which the user and the computer information exchange [2].

With the popularization of computers, more and more ordinary users started using the computer in contact, on the other hand also contributed to the development of computer hardware and software it has become the way people work, learn and important tool life. It is in this process, the status of human-computer interaction is becoming increasingly important, and it is the people know it is inseparable. Importance of the human-machine interface is that it is the interface between the user and the computer, which greatly affects the use of end-users. Today, a measure of the success of an application, the user interface is easy to become an increasingly important operational indicators.

Currently, thanks to other relevant computer technology such as the development of speech recognition, natural language understanding, gesture recognition, computer vision, and many other technologies, human-computer interaction research entered a new area of human-computer interaction more than one channel. The so-called channels, meaning people in this exchange of information with the computer the way, is the classification from the user's point of view in this way information exchange carried out.

Multi-channel human-computer interaction is developed in the traditional man-machine interface of an emerging technology, but also human-computer interaction techniques developed to a certain stage of historical trends inevitably arise. Direct manipulation of today's popular graphical user interface (GUI) there are still insufficient, mainly due to inconvenience users, even if it is difficult to integrate multimedia technology to change the fundamental problem [3].This is because although the GUI and direct mode of operation allows the use of computers has become intuitive, simple, integrated multimedia technology have greatly enriched the computer feedback manifestations , but the operation mode of the computer still does not change , the operator is still restricted next to the computer . Users can use according to their own habits and have to adapt to the computer, which is used as a tool for the computer itself, it is far from reaching its objectives. Because the instruments of its own starting point is to facilitate the use of human. Multi -channel technology, human-computer interaction is generated in this context. Multi-channel interaction through a variety of interactive features designed to use an integrated way that people feel the effect channels and channels in parallel and collaborative manner to interact with the computer task. It is the biggest difference with the traditional place interactive graphical user interface that simultaneously use a variety of interactive devices and the integration of information from multiple interaction channels. It is designed in the context of ergonomics , the exchange of information through research into the habits and behavior patterns , the integrated use of sight , speech , gestures and other new interactive channels , devices and interactive technology that enables multiple users can natural channel , parallel , collaborative approach to human-computer dialogue , integration of accurate and inaccurate input from different channels to capture user interaction intent to improve the efficiency of natural and human-computer interaction , and ultimately achieving people-centered interaction.

With the popularization of computers and more intelligent, the popular interactive mode cannot meet the needs of people interact. Especially under the concept of ubiquitous computing, human-computer interaction is needed breakthrough improvement, the need to develop a more user-friendly interactive methods and techniques. Multi-channel technology is a hot topic nowadays human-computer interaction technology. It is against this background, this article will present theoretical results at home and abroad, for the multi-channel technology research.

Enter the concept of multi-channel information fusion

In order to achieve the purpose of mutual understanding and the computer must be understood in different ways for people to do something about computers. Expression and understanding of the way

people are multi-channel, non-precise, descriptive, and understandable manner on rigid computer a lot, need to understand the precise input. For as long as the person concerned in the particular occasion communicators need to express the idea of fully demonstrated, the understanding of people take into account many factors, such as background knowledge, specific field units, communicators background knowledge to understand the user wants to express the precise meaning. And can finally understand. Understanding of computers is not the same, requires the user to enter accurate information, but also in accordance with very strict chronological order.

The way people communicate is a multi-channel, such as when people communicate using both languages, there are gestures, as well as the eyes, facial expressions and the way of drawing and so forth. The purpose of the multi-channel computer interaction is the customary way people try to manipulate the computer. The key question is which one is converted into a multi-channel computer can understand how the form of the process. We called multi-channel integration. In dealing with this problem have been proposed different models and algorithms.

(1) Layered fusion model

Stratified according to ideological convergence, the integration process into the lexical, syntactic and semantic layers. In the lexical level, there are multiple channels to express the same information. In other words lexical layer that unifies the different forms of input channels, at this level, the process of handling two or more channels though not the same. However, they express the content is the same, i.e., the contents thereof can be expressed by the same word. In the syntax layer, the layer primitives according to information from the lexical grammar specification into human-computer interaction, said command primitives, which means that primitive objects representing primitive object properties. In the semantic layer. The use of task-driven mechanism, combined into a primitive primitives various specific tasks. In the semantic layer, using task-driven mechanism, the original language combined into a variety of specific tasks.

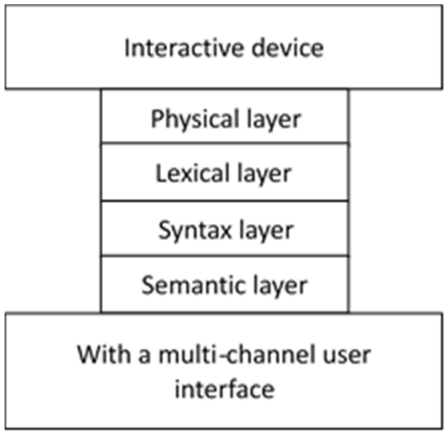

Figure: Hierarchical structure of multi-channel interaction

(2) Fusion model based on the probability of the alleged

Probability theory has a long history, it has successfully addressed many of the uncertainties related issues. There are abundant theories and systems. Probability fusion model is the main feature of the input event handling. In the probabilistic fusion mechanism, the event from any one channel are simultaneously sent to the action extractor, object extractor and various parameter extractor analysis and the results of each extractor and related parameters, including the results of the fusion probability, was sent to command fusion for further analysis, interactive commands and associated probability of formation of fusion. Fusion success probability depends on the input size.

(3) Multi-channel model of task-oriented interface structure

Multi-channel interface structure model ATOM-oriented tasks proposed by the domestic. The basic process of handling multi-channel interface is the input to block the flow of information, and make a proper understanding of the perceptual process. From the viewpoint of the task, the process is to capture user input, considering the passage of factors, contextual factors, interaction history information, to obtain the user's interaction with intent, the final

process of the formation of a task [4]. This process, the syntax constraint information input by the user becomes task configuration information, user information fusion process task is the formation of human computer interaction intention understanding.

Summary

The main topic of this paper is the pervasive computing environment, structure and method of program design of multimodal interaction. With the development of a variety of interactive technology, multi-channel technology will be put into practical application is more and more widely, according to the characteristics of multi-channel system, to study the module has a greater practical significance. Through the analysis of multi-channel system of semantic representation. A package model and algorithm more efficient template for multi-channel system developers call, is conducive to focus on design and function of the user interface and application related. At the same time, with the idea of modularization, improvement of multi-channel fusion model based on other multi - channel technology research results can only reflect to the template, then no need to change for multi-channel system using it.

Collective Communication Optimization for Solving Linear Algebraic Equations

Xiaoguang Ren, Wenhao Zhou, Juan Chen

State Key Laboratory of High Performance Computing

National University of Defense Technology

Changsha, Hunan 410073

hbszrxg@gmail.com

Keywords: Optimization, Linear Algebraic Equations, MPI, Collective communication

Abstract. With the development of the electronic technology, the processors count in a supercomputer reaches million scales. However, the processes scale of a application is limited to several thousands, and the scalability face a bottle neck from several aspects, including I/O, communication, cache access .etc. In this paper, we focus on the communication bottleneck to the scalability of linear algebraic equation solve. We take preconditioned conjugate gradient (PCG) as an example, and analysis the feathers of the communication operations in the process of PCG solver. We find that reduce communication is the most critical issue for the scalability of the parallel iterative method for linear algebraic equation solve. We propose a local residual error optimization scheme to eliminate part of the reduce communication operations in the parallel iterative method, and improve the scalability of the parallel iterative method. Experimental results on the **Tianhe-2** supercomputer demonstrate that our optimization scheme can achieve a much signally effect for the scalability of the linear algebraic equation solve.

Introduction

The performance of High Performance Computing (HPC}) had been greatly developed, and extended to E-scalar. However, the HPC applications cannot fully take the advantages of HPC performance as the scalability problem. The scalability problem means that the application performance cannot extend with the processors count, even show up a negative speedup when the application takes massive processors. There are various bottlenecks cause the scalability problem, including I/O problems, memory access, load balance, and communication, among which communication is the focus of this paper.

Linear algebraic equations solving is the core module of most scientific computing, especially the partial differential equations (**PDE**) solving. According the researchers' work, linear algebraic equations solving accounts for up to nearly 70% of the whole scientific application execution time, whose performance plays a critical role in the scientific computing.

Linear algebraic equations solving also faces the scalability problem, which concentrates on the communication bottleneck. Message Passing Interface(**MPI**) is a defacto standard for HPC communication, and the communication operations can be classified into point-to-point communication and collective communication. Collective communications essentially are synchronization operations, and heavily limit the performance of linear algebraic equations solving.

In this paper, we try to optimize the communication in the linear algebraic equations solving through reducing the collective communication operations. Iterative methods are the mainstream method for linear algebraic equations solving. Our work is on the base of the analysis of the iterative methods, and we try to eliminate some collective communications operations in the iterations, which will greatly enhance the scalability of the computing of linear algebraic equations.

The main contributions of this paper are summarized below:

- We analysis the feature of the linear algebraic equations, find that the collective communication operations are the main bottlenecks for the applications' scalability problem.
- We optimize the iterations method for linear algebraic equations through eliminating the collective communications, which will greatly enhance the scalability of the HPC scientific computing.
- We show by experiments on Tianhe-2 supercomputer with a typical iterations method for linear algebraic equations that our strategies have greatly improved the scalability of the linear algebraic equations solving.

Background

Linear algebraic equations. Solving linear algebraic equations is the core of most problems in computational mathematics. Most of the scientific computing problem is to solve the Partial Differential Equation (**PDE**), which is discrete into linear algebraic equations by various discrete methods like Finite Volume Method (FVM) and Finite Difference Method (FEM). Linear algebraic equation has the form shown as Eq.1:

$$Ax = b \tag{1}$$

Where A is a matrix, and b is a vector, x is the vector to be solved. Depends on the features of the PDE and the discrete mesh, the matrix A is tense or sparse, and the density of the non-zero elements in the matrix A is critical for the performance of the linear algebraic equations.

There are several algorithms for solving a system of linear equations: direct method and iterative method. In the problems of finding the root of an equation (or a solution of a system of equations), an iterative method uses an initial guess to generate successive approximations to a solution. In contrast, direct methods attempt to solve the problem by a finite sequence of operations. In the absence of rounding errors, direct methods would deliver an exact solution (like solving a linear system of equations Ax = b by Gaussian elimination). Iterative methods are often the only choice for nonlinear equations. However, iterative methods are often useful even for linear problems involving a large number of variables (sometimes of the order of millions), where direct methods would be prohibitively expensive (and in some cases impossible) even with the best available computing power[1].

In this paper, we mainly focus on the iterative method, and take the Preconditioned Conjugate Gradient (PCG) method as an example to demonstrate our propose. The preconditioned conjugate gradient method takes the following form:

Algorithm 1 Preconditioned Conjugate Gradient Method

1: $r_0 = b - Ax_0$
2: $z_0 = M^{-1}r_0$
3: $p_0 = z_0$
4: $k = 0$
5: **while** $|r_k| < tol$ **do**
6: $\quad \alpha_k = \frac{r_k^T z_k}{p_k^T A p_k}$
7: $\quad x_{k+1} = x_k + \alpha_k p_k$
8: $\quad r_{k+1} = r_k - \alpha_k A p_k$
9: $\quad z_{k+1} = M^{-1} r_{k+1}$
10: $\quad \beta_k = \frac{z_{k+1}^T r_{k+1}}{z_k^T r_k}$
11: $\quad p_{k+1} = z_{k+1} + \beta_k p_k$
12: $\quad k = k + 1$
13: **end while**

Where *tol* is the floor of the residual error, and x_{k+1} is the solution result. The whole algorithm do the iterations until$|r_k|$ is smaller than *tol*.

Parallel scalability of iterative method. We still take PCG method as an example to demonstrate the parallel scalability of iterative method, the parallel implementation of PCG has been described in many papers[2-4]. The parallel implementation of PCG mainly on the base of block partition, i.e. decompose the matrix A and vector b into several parts, and each part is computed by a

process. The block matrices is shown in Fig.1, where the matrix A is divided by row as well as the vector b, and each process computes a matrix block and a subset of b.

The scalability of a parallel application on a parallel system is a measure of its capability to effectively utilize an increasing number of processors[5]. However, the scalability of the iterative method is so poor that the speedup can't expand with the processors number. We test the performance of PCG with processors from 2 to 2048, the result of which is shown in Fig.2. We can find from the result that when the processors number is greater than 512, the speed up become negative.

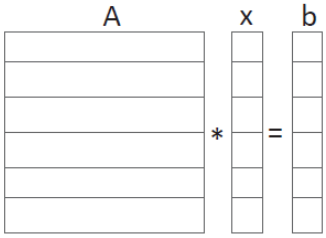

Fig.1 Parallel implementation of iterative method

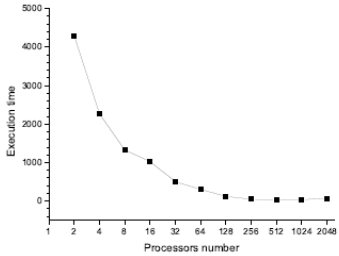

Fig.2 Performance of PCG with different processors number

There are several bottlenecks causes the poor scalability, including the cache block, I/O, communication, .etc, among of which, communication cost is the mainly reason for it. According to our experimental data, we test the communication cost in the iterative method for PCG method, as shown in Fig.3, the percentage of the communication cost increases with the processors number. When the processors number is greater than 1024, the communication cost will become the main cost of the whole execution time, and become the bottleneck of the parallel execution.

Communication bottleneck analysis for iterative method

In this section, we still take PCG method as an example to analyse the communication bottleneck for the parallel iteration method.

The parallel implementation is based on Message Passing Interface (MPI), which the d'fact standard for parallel is programming. There are two kinds of communication operations in the PCG method: point-to-point communication operations and collective communication operations. Taking PCG method as an example, as shown in Alg.1.

The point-to-point communication operations are mainly occurs in the matrix-vector multiply operation. When one row of the matrix multiplies a vector, the process just holds a subset of the whole vector, and a point-to-point communication operation has to be performed to exchange data between different processes.

As shown in Alg.1, there are three matrix-vector multiply operations in PCG method, respectively in line 6,8,9 of Alg.1. These matrix-vector multiply operations involves two point-to-point communication operations, and the data size of these point-to-point communication depends on the vector data to be exchange with other process.

As shown in Alg.1, there are two collective communication operations in PCG method, respectively in line 5, 6, 10 of Alg.1, which are respectively to calculate the scalar variables $|r_k|$, α_k, β_k. Take the calculation of β_k as an example, the collective communication operation is reduce sum operations, each process send its local variable β_k to the master process, and the sum of all the local variables value is calculated, and the sum result is broadcast to all the processes.

Although collective communication operation involves just a scalar data, it is a synchronization operation and a very time-consuming process. Because the collective operation in each process will not finish until all the processes done the collective operations, and the performance of the collective communication operation will be limited by the slowest process.

Through other researchers' work, the cost of various communication operations in PCG solver is tested, and the results are shown in Fig.4[6]. We can find from the results that collective

communication operations are the most time-consuming operations. Although the point-to-point communication operations (send and receive) occur most, the time cost of them are far smaller than the collective communication operations (reduce).

So, in the following sections, we will try to optimization the collective communication operations by reducing the number of collective communication operations.

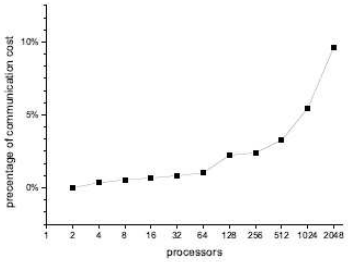

Fig.3 The percentage of the reduce cost increases with the processors number

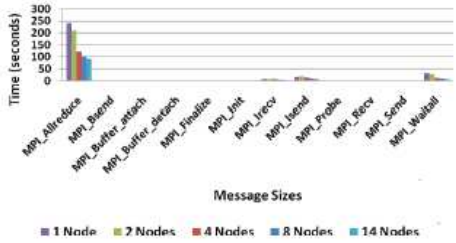

Fig.4 The time cost of different communication operations in PCG

Collective communication optimization for iterative method

In this section, we will demonstrate our collective communication optimization method for iterative method by taking PCG as an example. The core of our optimization method is to reducing the number of the collective communication operations as much as possible, especially the reduce operation.

The feather of PCG solver provides opportunity for our optimization. As the analysis in the former sections, there are three reduce communication operations, and the core of our optimization is to combine the reduce communication operations or eliminate it. So there mainly two optimization schemes for the reduce communication operations.

reduce elimination. The scalar variable $|r_{k+1}|$, the resid error has to be calculated for every iteration method for linear algebraic equations, which is used to check whether the iteration has reach to the convergence value. The compare between the variable $|r_{k+1}|$ and \$tol\$ is performed at the end of every iteration, if $|r_{k+1}|<tol$, the solution can be considered to be convergence and the iteration will be stopped. Otherwise, the iteration has to be continued until the condition $|r_{k+1}|<tol$ is met.

However, each calculation of the resid error $|\boldsymbol{r_{k+1}}|$ has to perform a reduce communication operation. As the roll of the compare between the variable $|\boldsymbol{r_{k+1}}|$ and tol is just to check whether the iteration should be continued, the compare can be cancelled at some condition. If the compare is cancelled, there will be no need to perform the calculation of $|\boldsymbol{r_{k+1}}|$, and the corresponding reduce communication operation will be also cancelled.

However, if the compare is cancelled, the iterations cannot judge when to stop. In this paper, we propose three schemes to solve this problems: Fixed iteration number, coarse check, and local resid error, and we will introduce them respectively.

Fixed iterations number: Instead of check the residual error for each iteration, we can set a fixed iterations number, and the iterations will continued without check until all the fixed iterations number had been finished. The reduce communication operations will be eliminated with the fixed iterations number scheme. In fact, most of the iteration number in traditional iterative method is dynamic. The disadvantage of the fixed iteration number is that the iterations number may be less or more than the actual value, so this scheme just valid for the iterative method with known iterations number.

Coarse granularity check: Instead of check the residual in the end of every iteration, coarse granularity check performs the residual error check in a coarse granularity, i.e. the check interval is more than one iteration, may be two or more. As the check interval last for longer time, the number of the residual error checks will sharply decrease, and the reduce communication operations also decrease with the residual error check number. Coarse granularity check can greatly reduce the

number of residual error checks as well as the reduce communication operations. However, if the residual error check interval consist too many interations, the total iteration number may be greater than the predetermined iterations number, and import external performance overhead. So the residual error check interval is very critical for this coarse granularity check scheme, and we will discuss this problem in the next section.

Local residual error: The root of the reduce communication operation in the calculation of residual error $|r_{k+1}|$ is that all the processes have to contribute to the final residual error value and get the final value from the root process. In our local residual error scheme, every process tries to calculate its own local residual error value without data exchange with other processes, and check it locally.

However, as the original residual error is the sum of the local residual error from all the processes, the local residual error will be less than the global residual error. To approximately keep the residual error check effect, the condition $|r_{k+1}| <$tol has to be met, here $|r_{k+1}|$ is the global residual error. We assume that $|r_{k+1}|^{i}$ is the local residual error in process *i*, and then we can get the following condition should be met Eq.2:

$$\sum_{i=0}^{n-1} | r_{k+1}^{i} | < tol \tag{2}$$

For a single process *i* out of *n* processes, we take a conservative scheme, i.e. the local residual error just had to meet the following equation:

$$| r_{k+1}^{i} | < tol / n \tag{2}$$

If every process meets the condition Eq.2, the condition Eq.3 will be also met.

In this local residual error scheme, all the processes will carry forward without synchronization with other processes, so all the processes will not reach the convergence point at the same time. If one process reach the convergence point firstly, it had to continue the iterations until all the processes reach the convergence point.

In a word, the three schemes above are suitable for different application background, but the most practical one is the local residual error scheme. We will check its performance in the experiment section.

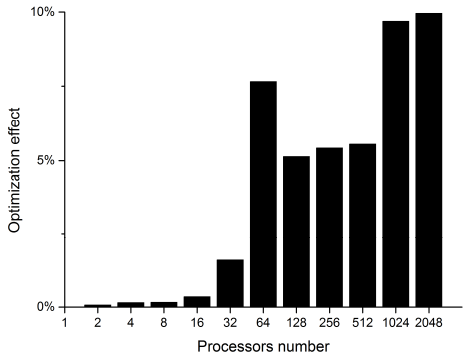

Fig.5 Optimization effect of local residual error scheme

Experiment

We demonstrate our scheme on the Tianhe-2 supercomputer with PCG solver in OpenFOAM framework. Subsection 5.1 discusses the OpenFOAM selected. Subsection 5.2 introduces the computer platform Tianhe-2 used in the experiments. Subsection 5.3 describes the methodology used for compare work. Subsection 5.4 presents and analyzes our results.

OpenFOAM. OpenFOAM is a open source Computational Fluid Dynamics (CFD}) software platform, which is based on Finite Volume Method (FVM}). There are multiple iterative methods for linear algebraic equation solving, including PCG method. We test the PCG method through a dambreak benchmark. dambreak is a simulation of dam break based on the volume of fluid (VOF) method. The two phase flow solver interFoam in OpenFOAM is used.

platform. The Tianhe-2 supercomputer was built by China's National University of Defense Technology (NUDT}), which is currently the world's fastest supercomputer with a 33.86 PFLOPS peak performance according to the TOP500 list in June 2013[7]. Our experiments use a subsystem of Tianhe-2 with 128 compute nodes as the test platform, and each computing node comprises two Intel Ivy Bridge Xeon processors, three Xeon Phi chips (accelerator card), and 64GB DRAM. It should be pointed out that our experiments only use the processors, rather than the accelerator card.

Evaluation methodology and result analysis. We tested our local residual error scheme in PCG method on OpenFOAM platform. The experiment mainly compare the performance of the original PCG solver and the PCG solver with local residual error optimization, especially the time cost of the reduce communication operations. As shown in Fig.5, it is the optimization effect of our optimization scheme, which is thetoltal execution time in the original PCG solver compared to the total execution time in the PCG solver with local residual error optimization. We can find that our optimization scheme can optimize about 9% of the total execution time.

Conclusion

In this paper, we analysis the bottleneck of the iterative method for linear algebraic equations solving, and find that reduce communication operations are the main reason for the parallel scalability problem. On the base of taking PCG method as an example, we propose three optimization schemes to reduce or eliminate the reduce communication operations. our experiment demonstrates that our optimization can significantly improve the performance of the iterative method.

Keywords: evolution rule, software architecture, trusted attributes, graph transformation

Abstract. In current software architecture evolution community, Trusted attributes of component are less considered; and the concept of trusted software architecture evolution has not generally agreed. Focused on above shortages, This paper propose the idea of trusted software architecture evolution, it helps to increase the trustworthiness of evolution; on the basis of graph transformation rule, establish some basic evolution rules, Evolution operations are implemented according to these evolution rules. It can ensure the exactness of evolution process. The paper also introduce E-R diagram to represent trusted software architecture evolution; and finally through an evolution case, exactly and visually describes the sophisticated evolution process of trusted software architecture evolution.

1 Introduction

With the rapid development of modern computer technology, especially mobile internet and internet of things, the complexity of external environment and software system itself is increasing, so software evolution is becoming more and more complex. Software Architecture(SA),which is considered as the foundation of software system, provides an effective way and basis for people to generally grasp software evolution. How to specify and analyze the evolution process in the architecture level has also been the key problem of the software evolution research[1].

SA evolution mainly relates to addition,deletion,replacement of components or connectors,and components relation and the change of its topology structure[2,3]. The literature [4,5,6] used graph to represent SA.The research effort in the literature [4] ,representing component using edge,representing communication port using vertex, focused on build of SA style and SA dynamic evolution; The literature [5] ,representing the superposition relationship of program using edge,representing program using vertex, depicted SA reconfiguration process by using graph rewriting rule. on build of SA style and SA dynamic evolution; The research effort in the literature [6] ,representing communication connection using edge,representing component using vertex, focused on describing SA style by using graph grammer. So each graph used in the literature[4-6] was endowed with different meaning. But these literatures did not focus on the research of SA evolution process defined on the basis of graph transition rule and based on some basic evolution operations as adding component,deleting component,etc.,also did not involve the trusted attributes of software system. The literature [1,4] made research on SA dynamic evolution based on hypergraph grammar,but did not involve the trusted attributes of component.The literature [7] proposed a kind of component model of supporting trusted software evolution, focused on improving the environmental perception and adaption ability of component to ensure trusted SA evolution, but did not specially consider trusted attributes of system, also did not involve SA evolution process on the premise of verifying trusted attributes of component.

So we can see that Although the investigator at home and abroad have launched much research on SA evolution, However, the concept of trusted SA evolution was rarely mentioned, the study on trusted SA evolution based on graph transformation rule was also rarely seen. This paper make the study on the conceptual ideas and evolutionary mechanism of trusted SA evolution, apply graph transformation rule to the SA change, describe the operations like addition,deletion and replacement

of trusted component through the change of the analogy diagram of representing SA, thus represent and specify the SA evolution process with some credible guarantee

2 The corresponding concepts

2.1 Graph transformation rule and SA evolution

Def.1 (graph transformation rule). A graph transformation rule P:L→R, it refers to a graph mapping relationship, let L be sub graph before transformation, R denotes the sub graph after one transformation.

Def.2 (Software Architecture,SA).SA of one software system includes the component,which is operating unit of system,the connector which connects components and specifys interactive behavior between components,and the configuration which formulates how to combine components and connectors together. SA can be expressed as a 3 tuple, $SA=(C_p,C_n,C_r)$,here,C_p represents the set of components ;C_n represents the set of connectors;C_r represents the set of constraints.

Def.3 (SA evolution). It refers to SA transformation such as addition,deletion,replacement,etc. of component or connector, and the corresponding change of interaction relationship between components and its topology structure due to some change, in which user requirements,running environments,software faults are , and other influences related to software system.

Def.4 (SA evolution rule). Let the corresponding graph of one SA be G, given a graph transformation rule P:L→R, if we have G' by using the rule to carry out one transformation to G, and the G' denotes the other SA, then P is called a SA evolution rule.

SA evolution rules can be applied to carry out SA evolution. given the graph G, which denotes one SA, and a SA evolution rule P:L→R, we can define the evolution process of applying P to G as the following:

1.Searching for the sub graph L' which is isomorphic to the graph L in the graph G, if successful then go on to step 2, else the rule P cannot be applied to carry out the evolution;

2.Deleting all the nodes and edges which are in the sub graph L', but not in the sub graph R, from the graph G;

3.adding all the nodes and edges which are in R, but not in L', into the graph G;

4.retaining the common nodes and edges of L' and R, meanwhile connecting the rest parts and newly added parts with the common parts of L' and R, and keeping the other parts of G unchanged, then we have the other graph G', the G' is the new graph denoting the SA after evolution.

Def.5 (SA evolution operation). It refers to some detailed evolution steps such as adding, deleting and replacing component, etc., for the graph representing SA by applying SA evolution rule to carry out.

SA evolution operation reflects SA evolution process, appears to a sequence of operations including addition, deletion,replacement,etc.of component or connector due to some reasons,e.g.,software function change,running environments change. The essence of SA evolution can be come down to modify the relationship between components.for example,when the functions of software system need to be expanded,it is ususaly to be needed to add new components;when some functions to be cut, to delete relative components needed.

2.2 Trusted SA evolution.

Trusted attributes are important elements of measuring software quality. software trusted attributes mainly include completeness for functions(Completeness), consistency for actions(Consistency), reliability for quality(Reliability) and security for program(Security). Completeness reflect to what extent software can realize its pre-design functions and satisfy users demands; Consistency refers to the capacity of maintaining no contradiction in the process of software running; Reliability reflects the system robustness to maintain functional properties confronted with special applications or unexpected errors; Security refers to the system capacity of preventing being used or refusing to services to unauthorized users in the meanwhile providing services to authorized users. The four attributes above comprehensively reflect software trusted characteristic, constitute the space of

trusted attributes, in which each attribute is composed of a vector of trust evidence, for instance, Reliability includes some trust evidences as the mean up time, the MTBF and the MTTR.

Def.6 (trusted attributes of component). It refers to attributes set of reflecting trusted characteristics like components quality and performance, including Completeness, Consistency, Reliability and Security.

The component is software function unit, is major portion of constituting SA and describing its evolution process. Trusted attributes of component can be analyzed and estimated by using state automation based on observation logic, protocol state machine and other techniques. According to several vector values of trust evidence, the integrated trusted degree of components can be obtained. When the value of trusted degree is greater than or equal to setting threshold value, the component could be seen as to be trusted. Only Trusted components are allowed to be evolved. The evolution of non trusted components is prohibited because it may conceal risks, for example, it may results in spreading errors if the components which are not available in one or several functions are evolved.

Def.7 (trusted SA evolution). It refers to SA evolution on the premise that the value of trusted degree is not less than threshold value when trusted attributes of components like Completness,Consistency, Reliability and Security were verified.

3. Basic operation of trusted SA evolution

3.1 **Analogy E-R diagram representation of SA**

In the design of database, we often use E-R diagram(Entity Relationship diagram). Here we introduce it to represent SA with trusted attributes to specify trusted SA evolution, each of its parts is separately given new representation meaning: rectangular box represents component; diamond box represents relationship; oval box represents trusted attribute of component.Connecting line with mark represents connection and interaction relationship between component and connector. It is called analogy E-R diagram, which is applied to represent software architecture with trusted attributes (SA-T). Fig.1 shows one SA-T represented with analogy E-R diagram. it includes 3 components:Client,WebServer and OracleS,each component is attached to four trusted attributes, such as Completeness, Consistency, Reliability and Security; 2 connectors:C-W connector and W-O connector; 4 edges, which are labeled with marks(named labeled edge):connecting the corresponding component to connector, showing the connection relationship between them, and reflecting interaction of each other,the mark on the edge indicate the news conveyed from component to connector,while the mark under the edge indicate the news from connector to component. for example: R_{Client}, $R_{webServer}$, $A_{oracleS}$, independently represents client request, webserver request, OracleS response.

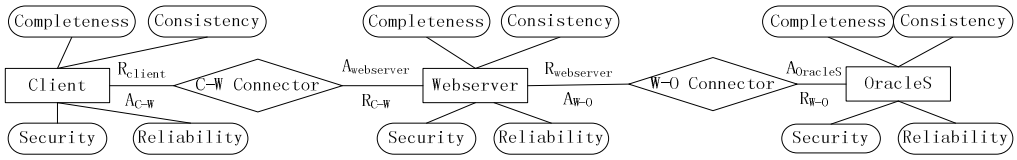

Fig.1 SA of Client/WebServer system represented with analogy E-R diagram

Def.8 (SA-T diagram). It refers to a SA diagram with trusted attributes represented by using analogy E-R diagram, it can be described as a 5-tuple $G_{SA}=(V_{SA},E_{SA},e_{cp},e_{cn},AR_{SA})$

For example, the fig.1 is a SA-T diagram. In G_{SA},V_{SA} is the nodes set, indicating all components and connectors in SA-T diagram, namely $V_{SA}=(C_p,C_n)$, C_p is the set of components, C_n is the set of connectors; E_{SA} is the set of labeled edges, indicating connecting relationship between component and connector(namely can indicate the communication ports between two sides); Both e_{cp} and e_{cn} are the set of mark on labeled edges, indicating the interaction relationship of each other, e.g., e_{cp}:$C_p \rightarrow C_n$,indicating message input from components to connectors, is marked on labeled edges; e_{cn}:$C_n \rightarrow C_p$, indicating message input from connectors to components, is marked under labeled edges. AR_{SA} is the set of trusted attributes of component, including four trusted attributes such as Completeness, Consistency, Reliability and Security.

In SA-T diagram, the component c_i, connector cn_i can be described with unary relation $C_p(c_i)$ and $C_n(cn_i)$; The connecting relation between component c_i and connector cn_i, namely connecting edge e_i between them, can be described with binary relation $e_i(c_i,cn_i)$; The interaction relationship between component and connector, namely e_{cp} and e_{cn}, which indicates the relationship of message passing ,can be separately described with unary relation $cp(e_i)$ and $cn(e_i)$, $cp(e_i)$ represents the input message from component c_i to connector cn_i on the edge of e_i, while $cn(e_i)$ represents the input message from connector cn_i to component c_i; Four trusted attributes of component c_i can be separately described with AR_{ci}(Completeness),AR_{ci}(Consistency), AR_{ci}(Reliability) and AR_{ci}(Security). Since each component is with above-mentioned four trusted attributes attached, in the process of evolution, they are added or deleted together. In order to express succinctly, the formalized description of four trusted attributes is be omitted when we give evolution rules in section 3.2.

3.2 SA evolution rule and evolution operation

One SA-T diagram represents a SA with trusted attributes. However, SA-T diagram can be considered as a kind of graph, graph transformation rule can be applied to SA-T diagram transformation. For example, Both rectangle box representing component and diamond box representing connector can be seen as the nodes in graph. The labeled edge connecting component to connector can be seen as the edge in graph. According to the formalized relation description before and after SA diagram change, we can define evolution rules for trusted SA evolution. Trusted SA evolution is based on these evolution rules, consists of a sequence of basic evolution operations. Basic SA evolution operations have addition, deletion, and replacement of the component or connector, the other complex evolution operations like splitting, recombining the component or connector, parallel evolution, etc., can be compounded of some basic evolution operations. To facilitate expression, we only give four basic evolution rules below, including adding component, adding connector, deleting component and replacing component. Meanwhile, we give the figures that show the corresponding SA-T diagram transformation to exemplify the trusted SA evolution process.

3.2.1 Adding a component or connector

Assuming G be the current SA-T diagram, the following formula (1) gives the evolution rule of adding a component c_i ; and the formula (2) gives the evolution rule of deleting a connector cn_i

$$G \rightarrow G \cup \{C_p(c_i),e_i(c_i\text{-}G(cn_i)),cp(e_i),cn(e_i),\ldots\} \quad (1);$$

$$G \rightarrow G \cup \{C_n(cn_i),e_i(G(c_i)\text{-}cn_i),cp(e_i),cn(e_i),\ldots\} \quad (2);$$

In formula (1), $C_p(c_i)$ denotes the component c_i; $e_i(c_i\text{-}G(cn_i))$ denotes the edge connecting the component c_i to the connector cn_i in the SA-T diagram; $cp(e_i)$, $cn(e_i)$ indicating the interaction between the component and the connector on the edge e_i, respectively denote input message and output message of the component c_i. Maybe the newly adding component has connecting and interaction relationship with multiple connectors, more than one newly labeled edges need to be added accordingly, so "…" is used to denote omission, like this, the "…" is used in the other evolution rules to be given below. In formula (2), $C_n(cn_i)$ denotes the connector cn_i; $e_i(G(c_i)\text{-}cn_i)$ denotes edge connecting the component c_i in the SA-T diagram G to the connector cn_i; $cp(e_i),cn(e_i)$ respectively denote their interaction relation; The fig.2 describes the SA evolution process of adding component c_i and connector cn_i.

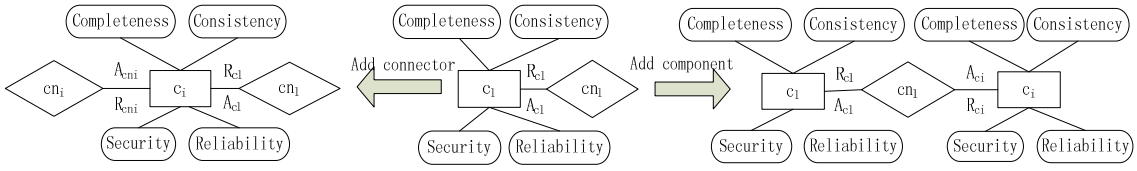

Fig.2 Adding a component/connector

3.2.2 Deleting and replacing a component

Assuming G be the current SA-T diagram, the following formula (3) gives the evolution rule of deleting component c_i ; and formula (4) gives the evolution rule of replacing component c_i with component c_k.

$$G \rightarrow G\text{-}\{C_p(c_i),e_i(c_i\text{-}G(cn_i)),cp(e_i),cn(e_i),\ldots\} \quad (3);$$

$G \rightarrow G-\{C_p(c_i),e_i(c_i-G(cn_i)),cp(e_i),cn(e_i),\ldots\} \cup \{C_p(c_k),e_k(c_k-G(cn_i)),cp(e_k),cn(e_k),\ldots\}$ (4);

When a component is out of use, formula (3) can be applied to delete it from its SA-T diagram;when the system need to replace a component, rule (4) can be applied to carrying out the corresponding SA evolution operations. The fig.3 describes the SA evolution process of deleting a component and replacing a component.

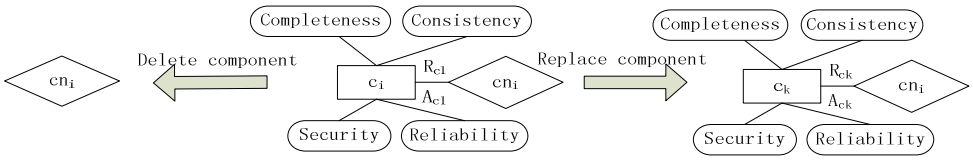

Fig.3 Deleting a component and replacing a component

4. Conclusions

Software evolution has become a existing form of software, is indispensable in the software life cycle. Architecture evolution reflects software evolution from a higher abstraction level, is an important means to study and implement software evolution. Focused on some problems in trusted SA evolution research, like its concept confused, modeling theory deficient, this paper proposes the concept of trusted SA evolution; establish some basic evolution rules based on graph transformation; introduces E-R diagram to represent SA with trusted attributes, carrying out evolution operations according to evolution rules, specify basic evolution process of trusted SA evolution. The approach presented in this charter has formalized basis of graph, and also has graphical concision.On the foundation of this paper, further, we will investigate the perception and verification of trusted attributes of component before SA evolution, the description of behavioral semantics evolution for SA, and so on.

Keywords: CityEngine; Environmental Noise; 3D Graphic Expression; CSG; B-Rep

Abstract. Based on CityEngine as software platform, this paper put forward 3D graphic expression of environment noise, and establishes the environmental noise monitoring model of 3D space by CSG and B-Rep hybrid algorithm. Then, according to the noise data and the legend of the color grade, we render the surface area of the 3D monitoring geometric model with the expression of grid method. Finally, the simulation shows that this method can be applied to 3D graphical expression of environmental noise.

Introduction

Now, the study on the environmental noise map model and city environment evaluation system is mostly based on 2D plane, but there is not too much research on modeling and data analysis of the vertical dimension. With the development of the virtual city area, city construction tends to 3D. The research on distribution law of the environmental noise pollution of 3D city space can help to use the space resources of city more reasonably. Situation of noise pollution in 3D space can be showed intuitively by expression of 3D graphical environment noise which can be used in city planning, transportation and environmental protection. Therefore, the study of 3D graphical expression of environmental noise has practical value.

Esri CityEngine, a new member of the GIS system modeling software [1], can be used for digital cities, urban planning and other aspects of 3D simulation [2]. Because Esri CityEngine supports geographic information data types of Shapefile and Geodatabase which makes the basis of existing GIS data can be used directly without any conversion, and also shortens the construction period of the 3D GIS system [3]. The rules based on CGA (Computer Generated Architecture) in CityEngine can be used to analyze the component of 3D model [4], the release of CityEngine makes 3D solution of ArcGIS more perfect. The applications of CityEngine based on the above characteristics are now increasingly used in various fields, such as urban parametric modeling [5], batch modeling, rapid prototyping, virtual reality [6], city planning [7] and other areas. In the environmental noise evaluation of the past, 2D environment noise graphical expression is the mainly research content, but compared with the 2D graphical expression of environmental noise, 3D can be more close to the real noise distribution. So the 3D graphical expression of environmental noise will become the development trend. By consulting the CityEngine literature, has not found its application in the field of environmental noise assessment. Combined with 3D modeling algorithm and the environmental noise related method, the author puts forward the application of CityEngine in 3D graphical expression of environmental noise and does some research in the establishment of monitoring model and space environment noise expression method.

Establishment of 3D Space Environmental Noise Monitoring Model

In order to reflect the distribution of the environmental noise in 3D space entities, when we set up the 3D model of environmental noise monitoring we must base on the model of the 3D space geometric entities. We put the noise monitoring points in the place of buildings' sound point to get

the value of the noise data. There are two ways to set up the model of the 3D geometry. First is CSG(construction solid geometry), it is set up by Boolean operations, the other one is B-Rep (boundary representation), it structures the entity by describing the characteristics of the entity (point, line, surface) boundary. If we use the structure of CSG, first, we should do the geometric decomposition description of the entity, divide it into simple geometries based on the decomposition rule, and then we can get a group of CSG geometry voxels [8]. Geometric primitives can be divided into basic and expanded CSG voxels. The process of this decomposition to 3D geometric building shows in Figure 1, divide a single building into parts of A, B, C, and D. The CSG modeling algorithm has the characteristic of simply method, simply data structure, small amount of data and so on. But the CSG has local to empress the entity and it is hard to change any part of the entity after finish it, that all because of limiting of types of voxels. The describing objects of the B-Rep model is the boundary of the space, it is the pyramid structure of point, line, surface, volume. The describe information includes the geometrical information and topological information. B-Rep model pays the most important of the external details of 3D space goals. The geometrical information and topological information of the 3D space are recorded by correlation chart of the point, line, surface and the 3D attribute table, thus can spatial analysis functions easily. The Figure 2 is the representation of the 3D geometric entity by B-Rep. The characteristic of the B-Rep algorithm is the relation information of the point, line and surface. And the B-Rep algorithm also has limitation, such as the poor ability to describe the entirety of geometric objects, can not record the original data and the large need of information when describing the entity.

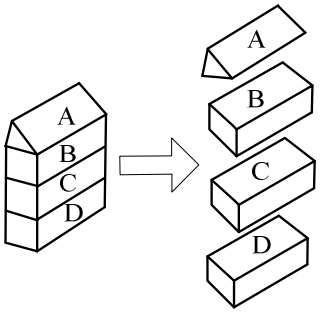

Fig.1. The process of CGS decomposition

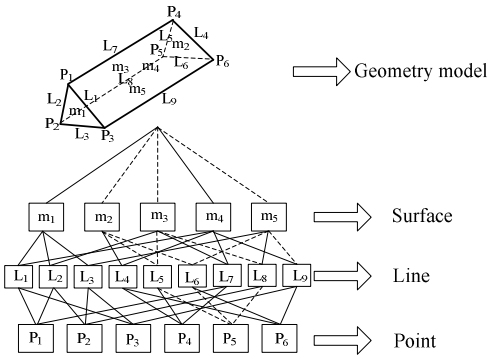

Fig.2. The process of B-Rep decomposition

It is need to layout noise monitoring points in 3D space the environmental noise monitoring model, and also need visual analysis which is based on the noise data. The CSG algorithm is able to express the basic building blocks of geometry, but lack of the expression of the surface, in this aspect; it can be supplemented with the B-Rep algorithm [9]. So the method of combining two algorithms could be used to build 3D monitoring of environmental noise model. Then the model is closer to reality, and also in favor of setting environment noise monitoring points and the expression of the surface of geometrical model. Figure 3 is a flowchart which is based on CSG and B-Rep mixed algorithm to achieve environmental noise 3D monitoring model.

The Process of Environmental Noise 3D Graphic Expression

Apply CSG and B-Rep hybrid algorithm, 3D model texture and CGA rules to constitute the environmental noise 3D space monitoring model, and grid the geometric model. According to the environmental noise data and its corresponding noise legend to render geometric model, to realize 3D graphical expression of environmental noise. The whole process is shown in Figure 4.

The Method of Environmental Noise 3D Graphic Expression

In this paper, taking a single building as an example and using a-weighted sound pressure level as the measurement unit of environmental noise. We consult the noise emission standards of social life environment [10] which divided the acoustic environment areas into 5 types according to the

function, each of these standards are corresponding to maximum limits values of the noise pollution in daytime and nighttime. For example, class 1 standards are applied to residential areas, cultural and educational areas as well as institutions concentrated area, standard formulates the noise emission values shall not exceed 55dB (A) in the daytime and shall not exceed 45dB (A) in the nighttime. By analyzing the noise limit values in five regions, we design gradient color with graded levels to show environmental noise value, the color and noise corresponding value as shown in table 1.

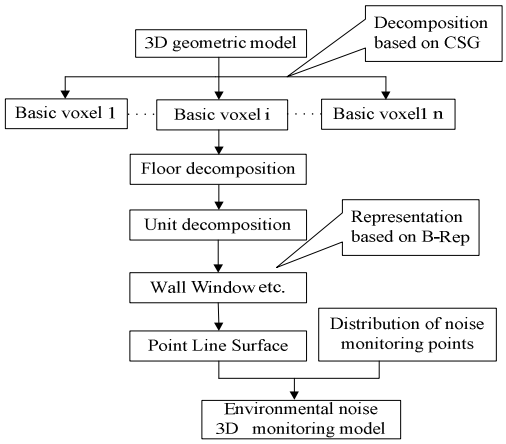

Fig.3. Flowchart based on CSG and B-Rep mixed

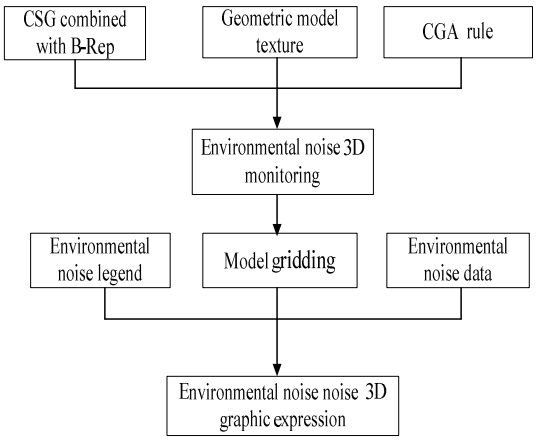

Fig.4. The whole flowchart

Table.1. Grade legend table

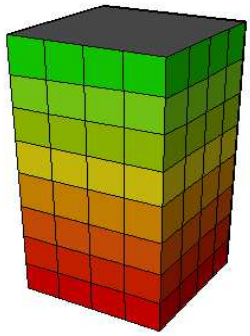

Fig.5. Example of the single building 3D environmental noise graphic expression

According to the grid design thought，the surface of each single building is divided into many grids the size of which is set according to the required accuracy environmental. Noise data can be derived from the manual measurement, but the manual measurement is not only time consuming, and the precision is also affected by human factors and a variety of geographic environmental factors. With the progress of science and technology, environmental noise automatic monitoring technology will become a trend. So distribution with the application of noise automatic monitoring technology can automatically obtain environmental noise data by sound region, as well as obtain environmental noise data by existing environmental noise prediction model combining related algorithms and rules. Then under the legend style as shown in Table 1 to determine the range of noise data belongs, each grid of 3D building are rendered with legend. The shown in Figure 5 is the single building 3D graphic example of environmental noise pattern. From the figure we can understand environmental noise pollution of each grid area, thus providing a three-dimensional environmental noise pollution conditions for residents, schools and commercial location.

In actual application process, the surface of single building is divided into grids with the grid design idea, the size of the grid is set according to the required accuracy environmental noise data can be derived from the manual measurement, but the manual measurement is not only time consuming, and the precision is also affected by human factors and a variety of geographic

environmental factors. With the progress of science and technology, environmental noise automatic monitoring technology will become a trend. So distribution with the application of noise automatic monitoring technology can automatically obtain environmental noise data by sound region, as well as obtain environmental noise data by existing environmental noise prediction model combining related algorithms and rules. Then follow the legend style as shown in Table 1 to determine the range of noise data belongs, each grid of 3D model are rendered with legend. As shown in Figure 5 for the single building 3D graphic example of environmental noise pattern. From the figure people can understand environmental noise pollution of each grid area, thus providing a 3D environmental noise pollution conditions for residents, schools and commercial location.

Conclusion

Taking CityEngine as software platform of 3D graphic expression of environment noise, combined with CSG and B-Rep hybrid algorithm, we establish 3D space model for environmental noise monitoring which not only can express the information of 3D geometrical model completely, but also has significance for the distribution of noise monitoring point on 3D model. Grid thought can be used to realize the 3D graphics expression of environment noise. The simulation results show that this method can be used as a 3D graphic expression method of environmental noise.

Keywords: Resource Scheduling Mechanism, CDIO, QoS, Big Data

Abstract. Since CDIO talents training informatization system is employed in Big Data era, this paper shows some studies on the application of the internet of things , cloud computing, Big Data service and other advanced technologies in CDIO talents training informatization system, an informatization framework for the internet of things and cloud computing is constructed based on CDIO talents training, in order to solve the difficulties in managing and monitoring the fully distributed architecture, a distributed resource scheduling mechanism with QoS is proposed.

Introduction

Big data has been widely used in various fields and is becoming increasingly mature because of its distributed computation, virtualization, cloud storage and other features. Similarly, big data platform will provide a large internet environment for knowledge application and innovation and thus lays a foundation for top notch talents training. The application of the internet of things and cloud computing to the field of CDIO talents training can meet the requirements for the collection, transmission, storage, management, processing, sharing and analysis of the data of various teaching links, and effectively improves the informatization level of CDIO talents training. It is a challenge as well as an opportunity to accelerate the establishment of such a CDIO Talents training system that is dominated by colleges and universities, guided by market, supported by enterprises and combines production with education and research.

Informatization framework for CDIO talents training based on the internet of things and cloud computing

(1) The conceptual model of the informatization framework for CDIO talents training

Fig. 1 shows the conceptual model of CDIO talents training informatization system based on the internet of things and cloud computing. This conceptual model preliminarily represents the following relationship. The data collected and processed by the equipment are first transmitted to the data center, and then managed, processed, computed and published by the cloud computing platform, and the final data resources and computing resources are accessed by clients through the application interfaces.

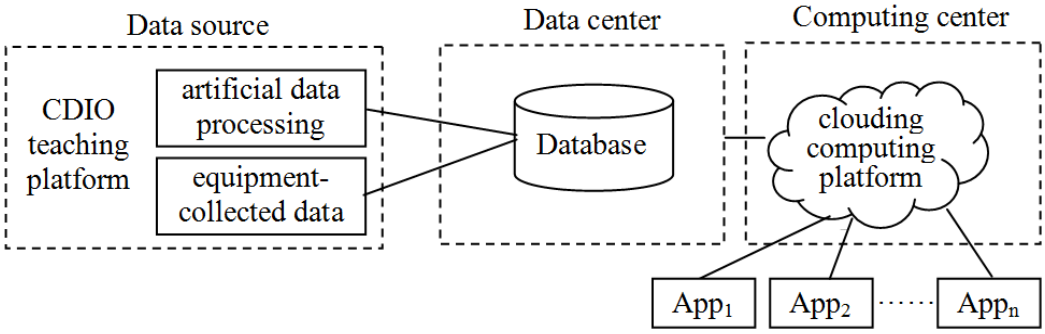

Fig. 1. Conceptual model of CDIO informatization system based on the internet of things- and cloud computing

(2) The framework model of CDIO talents training informatization

Fig. 2 displays the framework of CDIO talents training informatization system based on the internet of things and cloud computing (from the bottom to the top: internet of things of teaching, Big Data center, cloud computing platform of teaching, application). This framework is a complete architecture composed of data generation, organization, storage, query, analysis and service, and can provide reference for intelligence teaching.

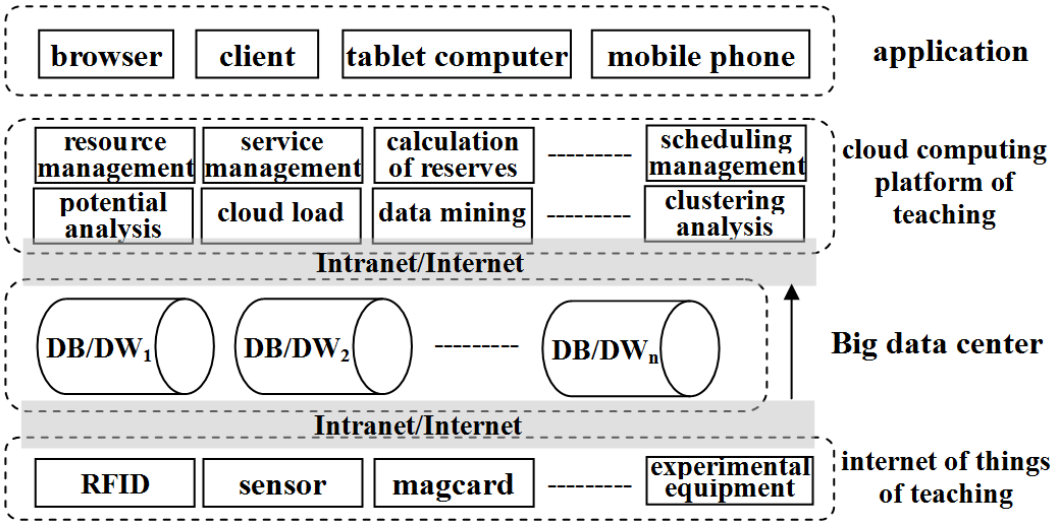

Fig. 2 Framework of the internet of things- and cloud computing-based CDIO talents training informatization system

The cloud computing-based distributed resource scheduling mechanism with QoS guarantee

The cloud computing architecture is usually centralized because of the requirements of business models, feasibility and maintainability. This paper proposes a distributed resource scheduling mechanism with QoS guarantee to solve the difficulties in managing and monitoring the fully distributed architecture.

(1) System model

Priority P1 and P2 are allocated to two kinds of users, and P1 is higher than P2. That is to say, the users with priority P1 has higher requirement for service response time than the users with priority P2. Higher priority is more likely to acquire high quality system resources, which will be discussed in detail in the following section. Similarly, this method can be used to easily extend the priority to n to meet the requirements of different business. Here, U1 refers to the users with priority P1, U1={U11, U12, …, U1(x-1), U1x}; U2 represents the users with priority P2, U2={U21, U22, …, U2(y-l), U2y}. When Priority=l, it means that the request is sent by the user from U1, and when Priority=2, it means that the request is sent by the user from U2.

Va is the average transmission rate of the network, Tr1 refers to the execution time cost by the user from U1 in reading the standard file under the experimental design environment, Tsa is the average addressing time of the hard disk, Tr2 is the the execution time cost by the user from U2 in reading the standard file under the experimental design environment, Tra refers to the average time cost by reading the data per unit, Tc1 refers to the execution time cost by the user from U1 in performing the computing task under the experimental design environment, W is the standard weight. If this standard weight is lower than the weight of the fragment resource combination allocated by the system to the user from U2, the request fails. Tc2 refers to the execution time cost by the user from U2 in performing the computing task under the experimental design environment. The time of storage-oriented business is as follows:

$T_{r1} = T_{sa} + n \cdot \delta \cdot T_{ra}$, $T_{r2} = n\delta / V_a + n \cdot (T_{sa} + \delta \cdot T_{ra})$

For the compute-intensive business:

$T_{c1} = T_{sa} + n \cdot \delta \cdot T_{ra} + \varepsilon$, $T_{c2} = n\delta / V_a + n \cdot (T_{sa} + \delta \cdot T_{ra} + \varepsilon)$

The QoS constraint of the system:

$T_{r2} \le T_r$, $T_{c2} \le T_c$ or $W_s \le W$, $W_c \le W$ 。

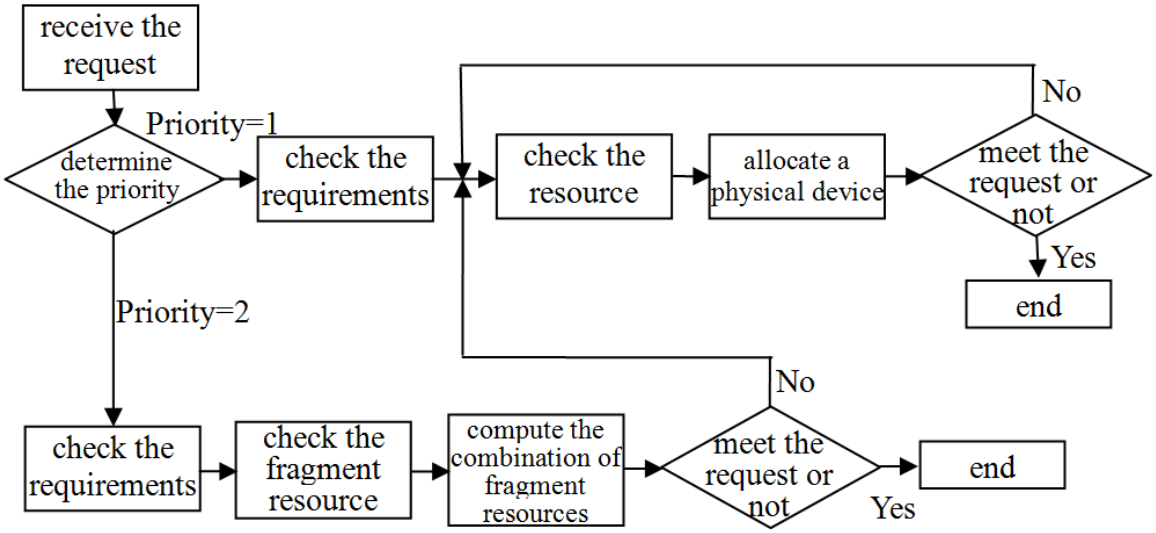

Fig. 3 Chart of the resource scheduling.

(2) A distributed, triple, resource search algorithm with QoS guarantee

It optimizes Chord algorithm and puts forward a distributed task scheduling algorithm with QoS guarantee to share the pressure of centralized schedulers. DQCRS simplifies the clouding computing system itself as well as the application design based on this system, and thus greatly reduces the adjustment and optimization workload of the system in this course.

Firstly, the system determines which type of operation is wanted according to the request R (CPU, Mem, Disk, type, Priority) submitted by the user. Secondly, the system uses the innermost Chord ring to look up and locate the hard disk storage resource that meets the requirements of the user, and then with the location of this storage resource as the fulcrum, the system uses the middle Chord ring to look up and locate the appropriate memory resource; finally the system looks up the appropriate CPU resource according to the location of the memory. The outmost Chord ring is first used to look up and locate the CPU resource that meets the requirements of the user, and then with the location of this resource as the fulcrum, the middle Chord ring is used to look up and locate the appropriate memory resource, and finally the location of the memory is used to look up the appropriate hard disk storage resource. The complexity of this algorithm is O (N *logn).

This search algorithm is located in “look up the fragment resource pool” and “compute the combination of fragment resources” of the flow chart as shown in Fig. 3. It optimizes the chord search process in the second and third rounds of the resource location.

(3) Simulation

The simulation result mainly shows the utilization rate of system resources when DQCRS is applied. In this experiment, the CloudSim simulation software is used to simulate the experiment environment. The experiment results indicate that DQCRS makes full use of the fragment resources in the cloud computing system, and certainly has higher utilization rate, about 13% higher than those systems which ignore the utilization of fragment resources.

Conclusions

Against the background of the age of big data and with the combination of the internet of things and cloud computing technology, this paper conducts an in-depth applied research on CDIO talents training informatization, builds the informatization framework for the internet of things- and cloud computing-based CDIO talents training and proposes a distributed resource scheduling mechanism

with QoS guarantee based on the improved Chord query algorithm. The simulation result shows that this mechanism can effectively improve the utilization rate of fragment resources of the system.

Research on Setting Strategy of Area Router Based on Scale-free Internet

SONG Junqiang [1, a]

[1]Wuxi Professional college of science and technology, Wuxi 214028, China

[a] SongJunqiang09@yeah.net

Keywords: interaction network; internet; scale-free; transmission structure; setting strategy; area router;

Abstract. Due to the large communication network, represented by the Internet such as: biological cell protein interaction networks, collaboration networks, air transport network, many real-world networks are proved to have the characteristics of small world network and scale-free (scale-free) connection properties, research on complex networks and dynamics mechanism has increasingly aroused people's attention.[1] For to the network, people are most concerned about is how to realize the information interaction without congestion, so in scale-free the basic connection problems of information flow transmission structure on the network is becoming a hot research.

Introduction

For the transmission of information to achieve efficient, there have been many studies have been devoted to the routing strategy is proposed to better. Some articles are proposed according to the topological connection information for routing selection judgment. This may apply to the nature of the test in small networks, but for changing wireless network connection structure similar to Internet scale network or high dynamic character, required for this routing strategy of large calculation and energy consumption is not satisfied. [3]So people begin to pay attention to the local routing strategy. Random walk strategy is the local routing strategy of the most primitive, but due to the random walk approach is too simple, the actual effect is very poor in the network. Wang Wenxu et al proposed a local routing strategy, the sending node is calculated according to the index specified neighbor node connectivity and Strategies of the forwarding probability, makes the routing, the routing of the fixed preference factor, so called static preference local routing strategy.[3]

The local routing strategy in this setting the neighbor nodes according to load the dynamic relationships and the ability to send fixed, preference factor adaptively adjust each neighbor node. First of all, the network information flow moderately concentrated to the node degree is large, increasing the utilization of high rate of the node, so as to effectively reduce the average transmission delay of packets in the network; secondly, shunt in the business increases, avoid some degree node supersaturated bring congestion of the whole network, as far as possible make full use of the ability to send all the nodes, improve the network capacity.

The model and definition

In order to losing the general B - A model proposed by Barabdsi and Albert as the basic structure of network, model generation method is similar to the reference, the node degree distribution has a power-law characteristics, namely P (k) ~ K-Y, y=3. [2]

The node degree with high betweenness large in a scale-free network, is the key node in the shortest path connecting nodes in concentrated on, so we should try to use the node degree in communication, making it easy to find the destination quickly (the call node scale-free network medium large as hub node); [4] when business intensified, it should be appropriate to shunt in order to avoid congestion in the hub node. Therefore in the packet generation rate is not high and all nodes are not saturated, it should make the node degree be greatly packet reception probability

preference; while in the node degree of saturation, the node traffic transfer to load light transmitting capability according to its load condition to reduce the probability of acceptance.

The transmission process is defined as follows:

(1) Every moment with R packets generated in the network, and then the packet generation rate is R, which selects packet source and destination nodes for each new generation randomly.

(2) Each node has the storage space of infinite hold packets, packet queue to obey the FIFO principle, transmission capacity of the node i fixed node connectivity ki. [4]

(3) All the nodes in the network at the same time as the cache will be sent to each packet of the next hop destination search and send. If the destination node information packet is the neighbor nodes of the current node, is directly put the packet to the destination node, and to eliminate the packet from the network. Otherwise, by preference in all the neighbor nodes, send packets to the neighbor node are the probability of i.

$$\mathbf{II_i = K_i^a / (\sqrt{K_j^{ai}})} \quad \textbf{(formula (1))} \qquad (1)$$

In the formula (1), ki is the node of I; AI is an adaptive node i adjustable selection index (later called the preference factor), in the initial time of all nodes preference factor is 0. The denominator is the sum of all the neighbor points. [4]

(4) Preference factor all nodes are updated in the network. The adaptive process is as follows: when a node i time stored information packet queue length is less than the transmission ability of Ki, the preference factor AI is increased by one step length; on the contrary, when the queue length of node i moment exceeds the transmitting ability of Ki, the preference factor AI can reduce a step length. At the same time as the preference factor set upper and lower Amax (>0), Amin (0 '). [5]

It is sequential steps of (1) ~ (4) completed service transmission at each time.

Set boundaries Amax, Amin reason is taken into account when preference factor growth is too large, the node preference probability of node will be far greater than the degree of smaller, packets will all try to large degree nodes, probability transfer to small node is very low, is not conducive to search the destination node in the network. To set an upper limit, so the Amax is AI; and the preference factor if the variable is lesser negative, means that the information will try to choose a small degree of ending point as the transfer object, completely avoid the hub node will cause the packet transmission delay greatly increased, so also to set the lower limit for AI amin. It should be noted in the adaptive transmission mechanism under the definition of this strategy, the length of l (KI) increased gradually from 0, when l (KI) ≤ Ki, the completion of each transmission will not have packets stranded at the nodes, so nodes in unsaturated steady state; on the contrary, if l (>ki, Ki). [1] Message packet will accumulate continuously in the node, the node in the supersaturated congestion state. So called l (k) =k as the node is not saturated phase boundary and the saturated.

Setting strategy

In the adaptive strategy, the selecting of any non-negative preference factor limit Amax can get the maximum network capacity Rc_max the same. This is because the adaptive strategies according to the relationship of load and the ability to send the changing preference factor AI, and then adjust the flow of information into the rate, continuously to the node unsaturated shunting packets so that the packets, not in the saturated nodes continue to accumulate, avoiding the node reaches saturation caused global congestion. Unsaturated node, because the queue length has been meet L (KI) ≤ Ki, the preference factor AI will increase with time, until it is equal to its upper limit Amax. In the feedback adaptive preference factor under saturated nodes, packet into the rate will be substantially equal to the transmission capacity, namely, the average queue length stable at the phase boundary L (KI) =ki, because of the phase boundary slope of 1, a reference type (1), preference factor to obtain saturated nodes close to 0. At the same time, taking into account, when all nodes are saturated,

preference factor AI is close to 0, the network to achieve the maximum capacity. So in any preference factor limits under Amax, network has only the maximum capacity of the same Rc_max. [3]

Below picture (2) is the reflection of the different transmission rate, an average queue length of node changes. The phase boundary is represented in the thick line graph. Nodes are not saturated, reflected in the diagram is the L (KI) does not contact the dividing line, then l (KI) subject type (1). With the increase of R, part of the node contact boundary began to enter saturated state, l (KI) also is divided into two sections. The average queue length is part of a larger saturated nodes and phase boundaries coincide, the average queue length is l (KI) =ki; another part of the node does not reach the saturated state, the average queue length keeping the original slope. [5]

$$L(K_i) \sim K_i^{1+\alpha max} \quad (2)$$

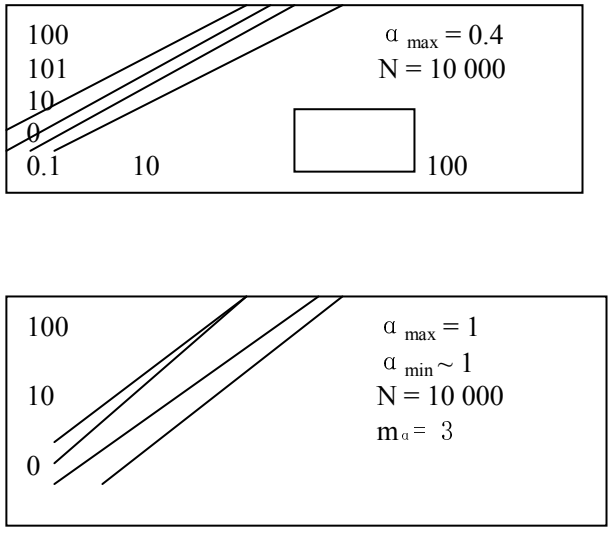

Figure 1. The reflection of the different transmission rate

Conclusion

Each node forwards probability by the node degree of K and a together determine the preference factor. Preference factor is regarded as a value of every node in the cache according to the average queue length adaptive changes. When the node cache average queue length is greater than the ability to send (equal to the node degree k), it will decrease a lot. Upper and lower limit of Amax a, Amin adjustable, and opposite number. When all the nodes in the network are not saturated, preference factor of different degree of nodes are basically reached the upper limit of Amax; when some nodes reaches saturation, the node preference factor shows that the statistical properties of a=0, the node preference factors still remain as amax. It makes the hand regardless of network business degree, which can guarantee the network information flow preferentially to the hub node, connected node degree is fully utilized; on the other hand can make the nodes transmit ability properly use and not to "saturated" state, adaptive to avoid the occurrence of congestion.

Keywords:Big Data; Information Technology; Local Government

Abstract：The era of big data is an inevitable trend of world development, environmental changes poses severe challenges around the local government of information construction in China. On the basis of the full analysis of the content and features of the era of big data, clarify the urgent need of the local government to further deepen the Information Construction in the era of big data, analysis the challenges for local governments of building big data era. On this basis, we propose a solution in the angle of the user, government resource integration, demand forecast and the government's responsibility.

1.The Meaning of the Era of Big Data

In modern society, although big data is a specialized vocabulary, yet it is closely related to each person's life: social networking tools and e-commerce platform in our daily life are both important part of the era of big data. Today, the network is becoming increasingly popular, whether the local government, which is close tied with the public life, can grasp the pulse of the construction of government information is not only related to its application and promotion of the work in local government, but also relate to achieve a successful transition of the government which is about to adapt the requirements of the current economic and social development. It is a key to judge whether government can complete the administrative and service functions or not.

Technological innovations is brought about by the information revolution. In the past, we have always put emphasis on "technology" of the information technology innovation, however, with the continuous development of information technology, the "Information" should be the basis of supporting the development of information technology. Therefore, when the technology reaches a certain level, we should give the "information" more attention. "Big Data" is a phenomenon and results that the development of the information age has reached to a certain level and the information shows explosive trends and accumulate to trigger the revolution. Vast amounts of information and data growth not only posed a serious challenge to the information and data storage, but also require for changing existing ideas and method of information and data processing. As a result, "big data" came into being.

Administrative activities of government, is largely an information processing activities. The level of government Informatization and information processing capabilities is not only the index of measuring the strength of the government, but also an important factor of efficiency. "Big Data" era is a major change for the way we live, work and think: it changes the previous surveys and statistical methods so that we can use all the data and not just a random sample; it changed our obsession with the pursuit of accuracy and allow Imprecision appeared as well as accept the existence of hybridity; it changed our stubborn pursuit of "causal relationship" and let us to focus on the "relationship" of discovery and use. Because of these changes, the information construction of local government is urgent and necessary in the era of big data.

2. Meaning and Necessity of the Government Information in Era of Big Data

2.1 Basic Meaning of Local Government Information

The government information is the use of modern information technology and related equipment, through a variety of information services, to develope and manage the information resources which the government needs.

The era of big data is an inevitable trend of future social development, and will promote the use of open data, and strengthen the open and transparent public information. At the same time, open data is bound to affect the work of government management innovation, local government behavior in the network society and real society interaction management will be greatly enhanced, thereby giving the local government new meaning and requirements.

2.2 The Necessity of Information of Local Government Information in Era of Big Data

In recent years, information technology has made significant progress in the development of China, information network and the intelligent terminals rapidly popularize, by the end of 2012, China's Internet users reached 564 million, Internet penetration rate of 42.1% for the 420 million mobile phone users, 309 million microblog users. Government network public service system has gradually formed, the central and provincial government websites penetration rate has reached 100 %, and the municipal government websites penetration rate reached 99.1%, more than 85% at district level. Although China is not treating big data strategy as a national strategy currently as the Western developed countries, but the relevant departments also showed the importance of big data will be presented at the National Science and Technology as National Basic Research and Development Plan, in February 2013 the basic research should focus on supporting large data calculated in the information sciences. In the era of big data, greater emphasis on transparency and sharing of information, local governments have become increasingly frequent interaction with the public, the extent and level of information technology directly affects the public impression and understanding of the ability that government administration; local government informatization of service-oriented government is also a window of public, it need to be paid more attention.

3.The Challenge of the Local Government Faced in the Era of Big Data

3.1 The Needs of Construction of the Information is More Urgent

In the era of big data, in order to better build a service-oriented government which give full play in communicating with the public, local government should expand channels of communication with people, improve the government portal platform through information technology, to strengthen communication and interaction between government and the public. At present, China has basically completed the establishment of local governments portals, but the efficiency of information integration and use is still relatively low, poor communication between the government and fragmented severely restricts the communication and sharing of information; addition, there are considerable number of local government portal merely hanging introduction on the line, and there is no link with the service information, the public demand for information on official line is difficult. It is not only stray far from the job which the government should do, even in mind different to the construction of informatization.

3.2 Lack of Information and Follow the Trend of Building Construction

Big Data era raise higher requirement of government information collection and storage of workers. However, for the government at all levels , to achieve the government 's information technology resources will face limitations and conditions which the objective conditions and resource shortages faced by local governments tend to be more prominent. Local Government preparedness capacity building in information technology, construction of the objective environment in which the information relative to the challenges facing more serious, far less can be done overnight. For example, compared to higher levels of government or government-developed regions, local governments do not usually have sufficient financial support , in addition to the quality of the civil service and general users can adapt the information reaches all need a process that requires a huge investment.

In addition, in local government information construction process, there are one-sided emphasis on common government information technology , the tendency to underestimate or even ignore the particularity of government information technology throughout its development stages; prevalence of one-sided emphasis on information technology capacity building, despise or ignore government defects environmental differences and environmental construction , there is a certain disregard its own special environment and conditions, blindly copy others' development model of information technology issues.

3.4 Local Government Needs to be Improved Utilization of Information Technology Facilities

In the quite a long time past, China's information infrastructure has been severely constrained economic and social development, accelerate the construction of information capacity, increase the supply of information and communication technology, information technology became a major task. But with the huge investment of resources in recent years, China's information infrastructure has made great progress in many places even a serious communication resources idle phenomenon. Again, a number of local governments disregard the local environment and user needs, the use of the funds is not sufficient to build a more powerful website online functionality, but not many users. In addition there is duplication of grass-roots government building information existing in the process, which will inevitably lead to unnecessary idle capacity and a waste of resources. While local governments directly to the public, in information technology should be more oriented to the needs of the masses, in order to facilitate the people as the goal, efforts to increase public acceptance of local government public information construction.

3.5 the Era of Big Data Related to Increased Risk of Data Misuse

In the era of big data to provide a lot of convenience to local governments and the public but also threaten our freedom and privacy. In the era of big data to make almost lost the ability to forget the whole society, the value of the data is not just based on its basic purpose, which is more secondary use, including forecasts. While the large data emphasize the correlation rather than causality between things, so local governments can organize relevant information to predict future events that may occur, such as grass-roots government through the analysis of relevant data to predict future events may occur in groups and take certain mandatory measures to prevent. However, the public should have done something for him to be responsible, rather than the data predicted by his behavior and responsible. However, current technology still can not analyze the authenticity of the data, we can not guarantee that the data is completely reliable, it is likely to make big data predict to some extent become a "punishment."

4. Strategies Big Data Era of Basic Government Information Technology

4.1 User-Oriented, Moderate Information Technology

The era of big data is released so that the government is no longer the sole source of information, the public enjoys a large degree of freedom of access to information and publishing rights , the traditional small data era is the era of government -led information sources lopsided , information dissemination and public become propagating body . The purpose of government information technology and administrative activities in principle the construction of a " citizen- centered, results-oriented and market- based" computer and network to carry out, to provide more efficient services to the public, so its operation becomes more rational and efficient virtual electronic government. Especially local governments , directly undertake the implementation of administrative work , the most contact with the public , so how can we meet the public demand for government information , how can the rational use of the information infrastructure owned by the Government to better serve the public , local government information technology must think about.

Here, the "User " refers to the actual use of government information resources of people, including public and government , including public servants . User-centric , information capacity builders and information service providers should listen to the views of users more fully consider the needs of users , in the case of resource constraints , the heavier users think business priority the actual utilization of the status of deployment , to create conditions to improve these business improvement services to improve user satisfaction with these services, and strive to achieve the relative

importance of services in the information technology , the reference uniform rate and service satisfaction. To avoid grass-roots government information construction process "information island " phenomenon and idle resources , should develop a unified planning and design of information technology of local government , we must have a long-term strategic vision to make investment in the construction of the current information technology facilities can adapt to the future of e-government development process , but also the construction of information based on the level of economic and social development of the region. Local Government final evaluation criteria and application of information technology should be controlled by the user 's hand.

4.2 Robust Relational Database, Integrating Government Resources

With the development of the process of government information, various local governments have their own portals basically established the level of government resources database, but not have integrated data resources within the library, which information mostly in scattered, isolated and quiet state. In the era of big data there is no longer limits to the use of the data for the first time, the use of data is more secondary or even multiple. Integrate the resources of the database can give full play to the relationship between the data through the use of correlation, we can draw a lot of new information.

Local governments should further collected in a database on the basis of the original information, rich library of data types, and data collected for classification. Meanwhile, governments and departments at all levels must break the monopoly and sealed of information to achieve the integration of government information resources, emphasis on the continuous development of information resources, updating and maintenance; construction of the repository of government information should be in accordance with national governing bodies of unified leadership, standardization of organizations in order to reduce the lack of standardization and regulation and a waste of resources , enhance sharing between government departments.

4.3 Predict Public Demand,Improve the Quality of Government Decision-making

Prediction is the core of large data. In the era of big data, due to the amount of data and more miscellaneous contents, the cost of government when collecting less information in decision-making and public policy feedback is more convenient. Because we can analyze more data, and sometimes we can process a particular phenomenon, without relying on random sampling. With the development of big data, a variety of social networking, instant messaging platforms will become tools for public comment in the media. Therefore, local governments can collect, mining and analysis big data through mobile phones, the Internet and other tools to response to the public opinion in time. Using of big data technologies, local governments may be have full consideration of public views and comments in early time, timely collection and processing of public feedback on the policy decision making process executed, to increase public acceptance and satisfaction of policy, thereby enhancing the quality of decision making.

4.4 Responsibility and Freedom of Both the Local Government Information Management

In the era of traditional small data, and the use of informed consent or fuzzy processing anonymized data can better protect user’s privacy, but in the era of big data, either because these traditional methods can confirm the correlation with each other, either too vague and cannot really protect privacy, or to be too narrow thus limiting the potential value of using big data, so there’s a very high risk of loss the privacy and the data protection is extremely difficult. There is no doubt that local government will face greater difficulties and risks because of financial or technology cause; also there are identifying difficulties and a higher risk when dealing with large data’s "prediction” function.

Therefore, local governments should emphasize principles of responsibility and freedom of information technology construction. The meaning of "freedom" is that local government allow free speech in the public network platform within the legal framework , local governments can use the portal to get the information needed; "responsibility" refers to the government 's obligation to protect its local public information data safety, the obligation to protect the rights of citizens equal access to relevant non-classified government information , the obligation to develop data antitrust-related policies and regulations and assist the legislature to introduce and implement the relevant laws.

Realization of RIP module on GPON OLT system

Wenhui KANG [a], Xiaohang HUANG, Shicai ZHANG, Xiaoyuan ZHANG [b]

Tianjin Normal University, Tianjin, 300387,China

[a]email: 1316675905@qq.com, [b]email: zh_xiao_yuan@126.com

Keywords: GPON; OLT; RIP

Abstract. As networks to be flattened, a direction has been put forward clearly by Telecom operators that Optical Line Terminals (OLT) of Gigabit Passive Optical Network (GPON) should become aggregation[1] OLTs, which makes them to work as both aggregation switches and edge access devices. According to this requirement, a scheme that realizes Routing[2] Information Protocol (RIP) on GPON OLT is put forward after deep analysis of GPON system[3] [4] [5] and RIP. Results shows that IP routing on GPON OLT is realized, which allows OLTs to work on the network layer, at the same time simplifies the broadband network levels and increases the reliability of the network.

Introduction

Recently，flattened network construction has attracted attention of operators, convergent optical line terminal (OLT) with large capacity, small office and high reliability gains more favor because of its contribution to the network construction cost. After a multi service transport platform (MSTP) of SDH, convergent OLT can access to backbone network, this simplifies the network level and saves the cost of operation and maintenance. Traditional GPON OLT works in the, so it needs switch in the convergence layer to access to the transmission network. If three layer routing function has been developed on the GPON OLT, it can work not only in the data link layer but also in the network layer, this conform to the development trend of flat network construction, and bring new challenges and competition for the development of GPON OLT. So, RIP routing protocol implemented in GPON OLT is becoming the focus of our attention.

GPON OLT system framework

Figure 1 is a block diagram of the GPON OLT system. From the chart we can see clearly the RIP module in the OLT system in place. Before the traditional two layer OLTs are all two layer interfaces, have no L3 interface model, so to realize RIP protocol on OLT, the primary work is to create three layer interface.

Realization of three layer interface and three layer driven

In order to realize the creation of three layer interface, we adopt supervlan technology, namely supervlan aggregation technology, Its principle is a supervlan contains one or more sub-vlans, each sub-vlan is a broadcast domain, two layers between different sub-vlan are isolated. A supervlan corresponds to a end driver, which contains two key points: the state of the supervlan and the IP address. These two key points determines supervlan can provide IP interface configuration and perceive the change of the state, thus users between sub-vlans can achieve three layer communication and RIP module can achieve three layer routing function.

In addition, we need to achieve some driving function in the exchange chip. First, there is a ACL module, the RIP module registers some protocol message dispatching rules to ACL module, then the ACL module send these rules to the exchange chip, so the exchange chip will only send the packets conformming to the rules to CPU to deal with, the packets not conformming to the rules are discarded. There is a three layer forwarding table, which contains three tables: the host routing table, network routing table and three layer interface table. Routing management module (RTM) manage RIP routing table, the exchange chip driver application program interface (API), RTM module calls these APIs to write the corresponding table into the three forwarding table of the exchange chip, ultimately to achieve hardware forwarding of three packets.

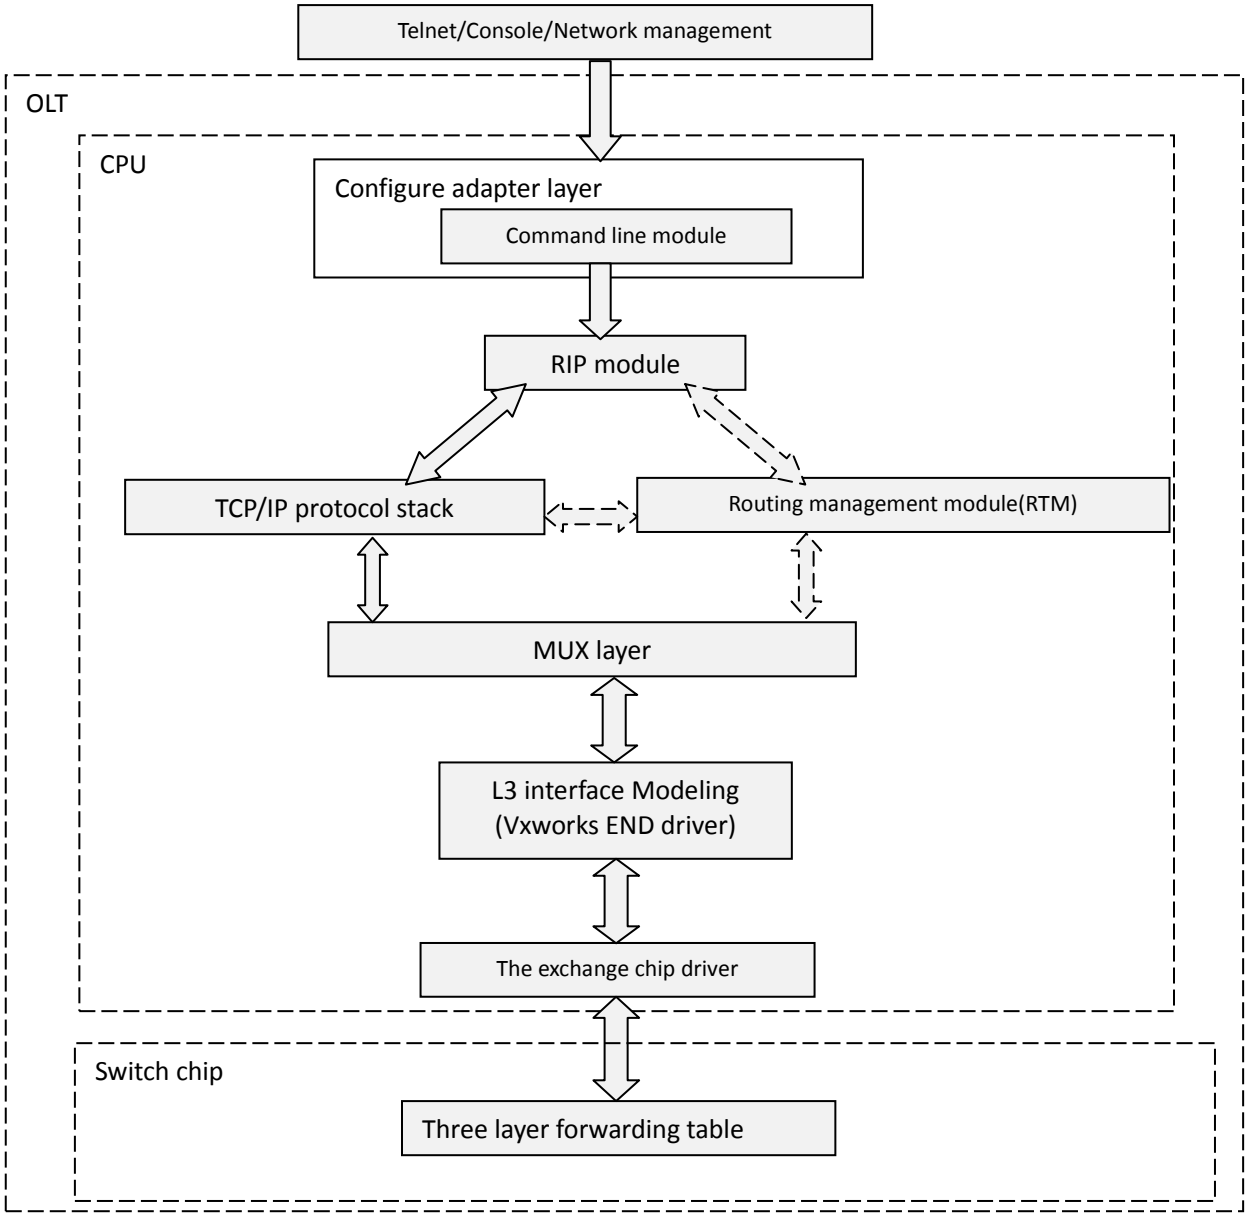

Figure 1 Diagram of the GPON OLT system

Implementation of RIP module

The overall structure of the RIP module as shown in Figure 2 can be separated into several sub module to achieve its function: the protocol module, network management interface module, input processing module, output processing module, Interface management module and RIP routing management module. Except the protocol module, the other modules are all responsible for communication with external module.

If network management interface module communicates with external network configuration module, external network configuration not only can be achieved through the graphical interface of network management but also can be achieved through the command line. But no matter which kind of form, that is needed to send related parameters configuration to the network management module, and then call the API of the network management module to achieve the control and management of RIP.

Input and output processing module communicate with TCP/IP protocol stack through the socket. TCP/IP protocol stack enables server socket. Because RIP is based on UDP, it is needed to create a SOCK-ET-DGRAM type socket to communicate with TCP/IP protocol stack. When we start an instance of RIP, the RIP messaging will be achieved through this created socket. The main function of input processing module is to obtain the protocol data packet received from interface, thus obtain routing information and peer information, and to give the response correspondingly according to the

type of data packet. The output processing module is to send interface function of a response message to the neighbor, form the response protocol, and through the RIP socket send the appropriate message to the adjacent router.

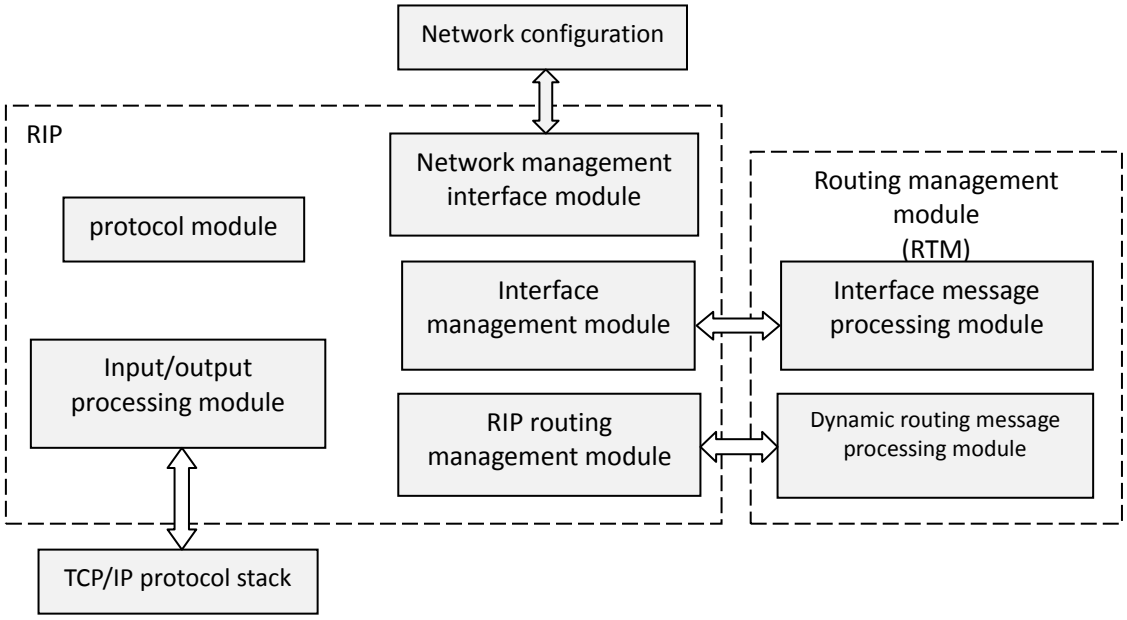

Figure 2 Structure of the RIP module

Interface management module is responsible for communication with interface message processing module of RTM module, they communicate mainly by sending messages with each other. In the RIP initialization interface management module register callback function to the RTM, when the underlying hardware changes, the bottom will notify the RTM, and RTM send corresponding status messages to interface management module of the RIP, then interface management module call corresponding callback function to change the port information saved in RIP system.

RIP routing management module is responsible for communication with routing the message processing module of RTM, it not only can send a message of receiving the routing to the RTM, but also can send a message of adding or deleting destination routing. If RIP want to redistribute a class of routing, such as redistribution of OSPF routing or static routing, it will send a message of adding redistribution to RTM module, and RTM will send the redistributed routing message back. Similarly, when a certain redistribution routing changes, RIP can send this message to RTM, and RTM carry out corresponding processing according to the message.

The protocol module does not communicate with any external module, it mainly process messages received from the input processing module or will sent out from the output processing module, and provide some interface functions for other module to get and set related information of the protocol entities, and directly call these interface functions.

Application of RIP protocol on GPON OLT system

After developing RIP routing software in GPON OLT, we apply it to a small network with voice services, network structure as shown in Figure 3.

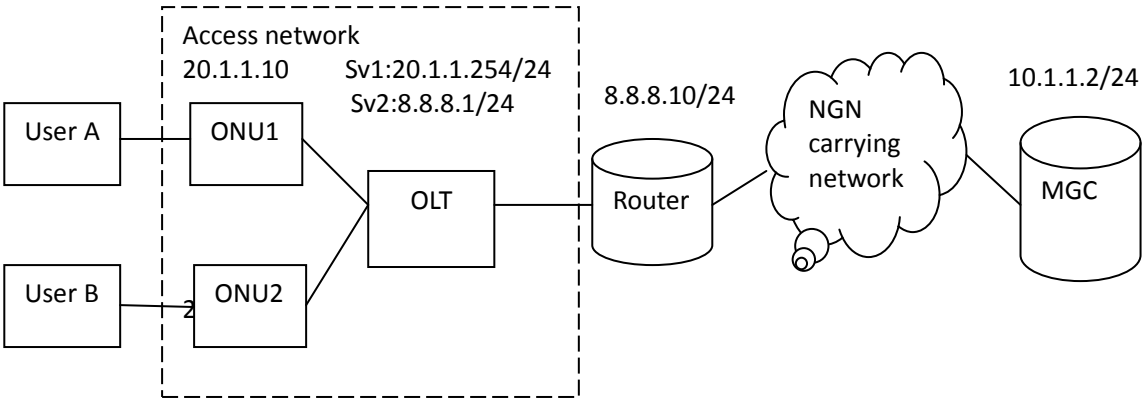

Figure 3 Network NGN voice service under three layer network

We will create two interface with three layers in OLT, as follows:

(1) Create Supervlan1 and Supervlan2.
(2) Create user side and network side Sub-vlan, two layer VLAN traditional.
(3) Join the user side Sub-vlan into Supervlan1, and join the network side Sub–vlan into Supervlan2.
(4) Configure IP address for Supervlan1 and Supervlan2, as shown Sv1 and Sv2 in Figure 3.

Open the RIP protocol in OLT and declared Sv1 and Sv2 corresponding network. If the user A under ONU1 want to phone with user B under ONU2, first of all they must be registered to the MGC (media gateway controller), through the MGC to establish a two-way channel between the user A to the user B and realize a normal conversation between them. To register with the MGC, they must send corresponding control signaling which is transmitted based on IP. Traditional two layer OLT must be externally connected with a three layer switch as the OLT gateway to forward the message. After implementation of the RIP protocol in the OLT, there is no need to pick the three layer switch in access layer of the OLT, we can directly open the RIP dynamic routing protocol in the OLT, and dock with the local side network which is planned well.

Conclusion

The characteristics of this scheme lies in that RIP protocol is introduced into the traditional OLT with two layers, this integrate the function of the aggregation switch and the edge router with no the need for construction of two layer convergence network, so it meets the need of the development of network operators, reduces the number of levels of broadband network and network nodes, saves network construction and operation the cost and greatly enhance the network reliability.

The scheme has been tested in the laboratory by scene. Of course, RIP has its limitation, the agreement provided that a valid routing information for metric cannot be more than 15, which makes the agreement not applied to large network.

Keywords: cloud platform, cloud computing, application mode

Abstract. Based on the background of Wuxi Software Park, building cloud platform system was proposed. The concept of cloud computing and cloud platform functionality was outlined. This paper studied the cloud platform application framework. Discoursing Park Intelligent Property Services cloud platform subsystem, park integrated services cloud platform subsystem and Park enterprise IT services cloud platform subsystem. The system can take advantage of cloud platform mobile terminal to provide application modes for companies, employees, park agencies, Software Park, operators and so on.

1. Introduction

Wuxi Software Park (iPark) is a scientific practice window of the new district to promote the optimization and upgrading of industrial structure. Its build-up area is 1.5 million square meters, including 0.55 million square meters which has been completed. It mainly includes the innovation and creative industry park, Jiangsu software outsourcing industrial park, sensor network information service park and so on.

Cloud computing is based on the addition of internet-related service and delivery mode used. It's always concerned about providing dynamically scalable resources by internet, which is always virtualized [1-3].

The establishing of cloud computing is to improve efficiency so that we can reduce the cost of enterprises. Physical separation can be achieved with logic together. In addition, efficiency can be significantly improved by virtualization, Thus operation cost, hardware cost and software cost will be reduced greatly. But in current trend of cloud computing development, the park is urgent to solve some problems in the process of setting up public service platform such as scattered resource, multiple managements.

2. Construction of cloud platform

IPark cloud platform will be mainly made up of cloud platform portal, park intelligent property, service cloud platform sub-system, park comprehensive service cloud platform sub-system, park enterprise IT service cloud platform sub-system and relevant public supporting infrastructure. It's planned on the whole and carried out step by step. Among them, main work contents of iPark's cloud platform construction includes park property and infrastructure's transformation, construction and integration; enterprises' online service for portals; individual self-help service system; IT service products supermarket's planning, designing, construction and operation.

2.1 Application system of intelligent property service cloud platform

Property systems concerning intelligent park management are security system, public management sub-system and apartment / building management sub-system. The wisdom park's four-staged intelligent property system of iPark is as shown in figure 1.

Construction and operation purposes of intelligent property service cloud platform in cloud portal mainly include: (1) parking and food consumption, bus ride, access control attendance card [4-5]. (2) releasing the park's public information(words, images, speech sound) , displaying unified resources management, providing channels such as image display and activities promotion for enterprises and sellers. (3) intelligent management of parking space and traffic [6-7].(4) introduction and practice of wireless park idea.

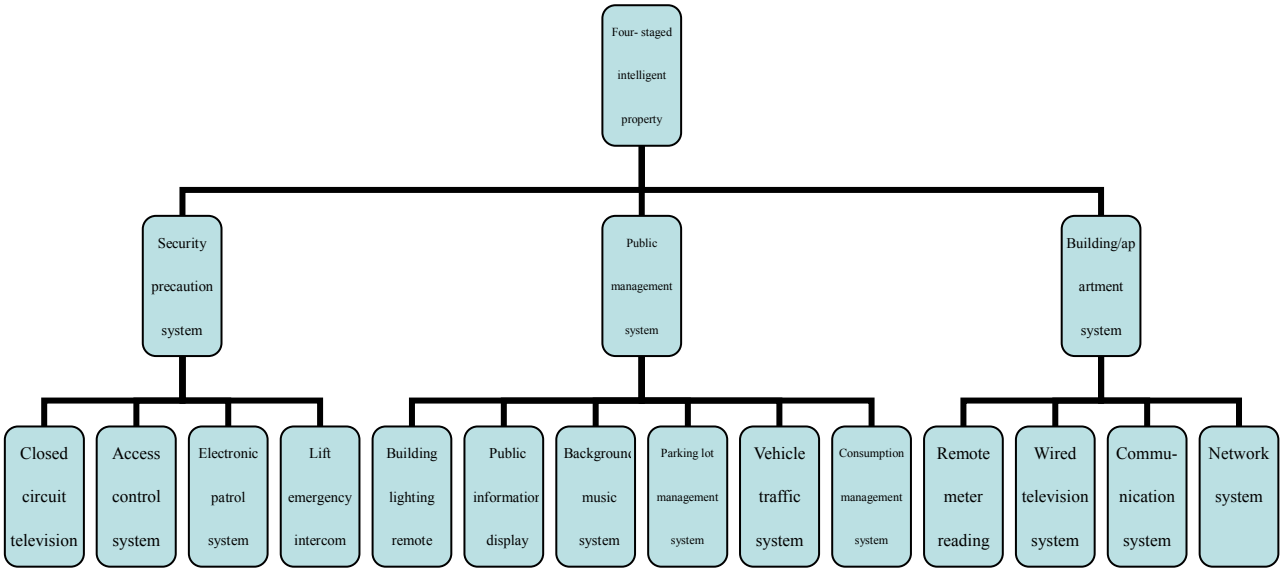

Fig.1: Four-staged intelligent property system of iPark

2.2 Application system of enterprise's IT cloud platform

IT service cloud platform is a generalized and open enterprise application service center, which needs to bring in and operate mature service business models and virtualized universal products from the industry. IT service cloud is orientated as operator of public service platform, which is more inclined to provide SaaS platform level service and serve online service suppliers [8-10].

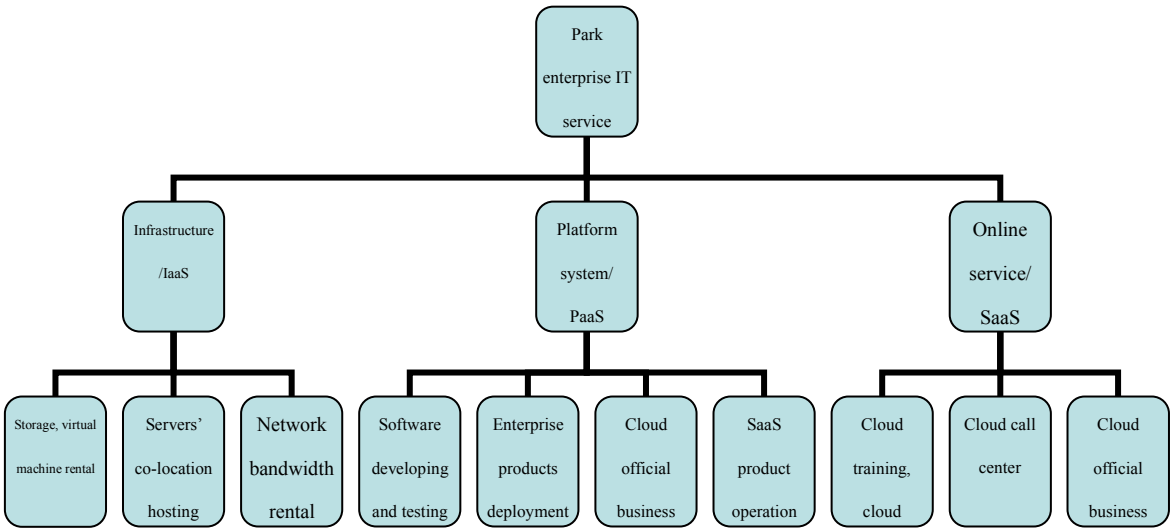

Fig.2: IT service cloud of enterprises in iPark

3. System application mode

3.1 Application of enterprises and staff members in park

Cloud platform will allocate automatically exclusive enterprise user ID for it from the time an enterprise is sure to settle in the park to its departure. The services as follows can be enjoyed by enterprise portals: (1)property services: housing rental, business handling, property repair handling, payment notice, enterprise online payment, query of expenses details and so on. (2) notice: information push, information subscription, complaints proposals and feedback. (3) image display: enterprises' dynamic information releasing in iPark web portals, recruitment releasing, enterprise information's updating. (4) industrial services: statistical investigation, form downloading, material uploading.(5) resource application: rental application of convention and exhibition center as well as public areas.

The park's staff members can register in cloud portals to apply for accounts, real-name registration in principle. They can enjoy the services: (1) property services: housing rental service handling, triple nets service handling and property repair service handling, notice of payment, personal payment, query of expenses details and so on. (2) announcement: information push, information subscription, complaints proposals and feedback. (3) resource application: rental application of convention and exhibition center, sports venues and public areas.

3.2 park institutions, business merchant application

After service agencies/merchants sign a cooperation agreement, the cloud platform will allocate and open exclusive platform provider user ID as "passage key" to interact information with their customers and software park management center in the process of carrying out business activities. Services provided for suppliers are: (1) property service: house rental service handling, property repairing service handling, notice of payment, enterprise online payment, query of expenses details and so on. (2) notice: information push, information subscription, complaints proposals and feedback. (3) image display: enterprises' dynamic information releasing in iPark web portals, promotion information updating and so on. (4) resource application: rental application of convention and exhibition center as well as public areas. (5) cooperative accounting: cooperative accounting agreement with the park, reconciliation, settlement of accounts, distribution and so on.

3.3 Application and Operation of Software park,

The software park is manager and operator by default, while some business operations of the service cloud platform(such as IT service cloud platform, operation and clearing business of the park's one-in-all cards, wireless network services and so on) could be packaged to operate by professional teams from the third party. As service center of park, it provides: (1) business handling and charging: housing resources (flat) leasing transaction service handling, property repairing service handling, public resources rental service handling, charging for call, online payment handling (well versed in both inside and outside with the software park inside business OA system); (2) all-in-one card business: card management, online recharging, query of expenses details and so on; (3) releasing and pushing of all sorts of information, enterprises/sellers releasing information audit, statistical investigation and so on; (4) complaints proposals acceptance and feedbacks; (5)

monitoring center: park entrance intelligent monitoring system with traffic guidance inside park, remote meter control, electronic patrol, closed-circuit television and so on.

4. Conclusion

The construction of iPark cloud platform system has realistic significance in these aspects. It will contribute to the development of Wuxi software park and science and technology industry inside the park and in the surroundings. It can improve customer service efficiency and specialization as well as fine management work efficiency and enhance the satisfaction of enterprises and loyalty of practitioners inside park. Also it could help establish iPark high-end brand image so that investment and construction, canvassing and settling, enterprise service can head towards a virtuous-circle direction. Each part of it has direct and indirect economic benefits and significant social benefits. It's economically viable, according with actual situation of the park's orientation and industry characteristics.

Keywords: APT; Network Attack; Social Engineering; Security Protection

Abstract. Advanced persistent threat (APT) has become a serious chanllenge to network security in recent yeas. Characteristics of this kind of network attack involve purposiveness，concealment，sustainability and variability, and it is hard to protect for critical infrastructure, financial systems, elements of national power, etc. These threats range from unwitting hackers to nation-states, each at various levels of competence. For performing security protection, five typical cases of APT including Night Dragon attack, Google Operation Aurora, RSA SecurID attack, Stuxnet attack and Shady Rat attack were analyzed. Its commonly attack process and technology characteristics are summarized. Finally, some suggestions and opinions on secrutiy protection were presented.

Introduction

With the development of Internet, network security is faced with the flinty challenge and the main security threatens are from new attacks which are characteristic of organization, aiming at special target, sustainability, etc [1][2]. This kind of threaten is usually called APT (Advanced Persistent Threat) attack and its specific connotation can be shown in Figure 1.

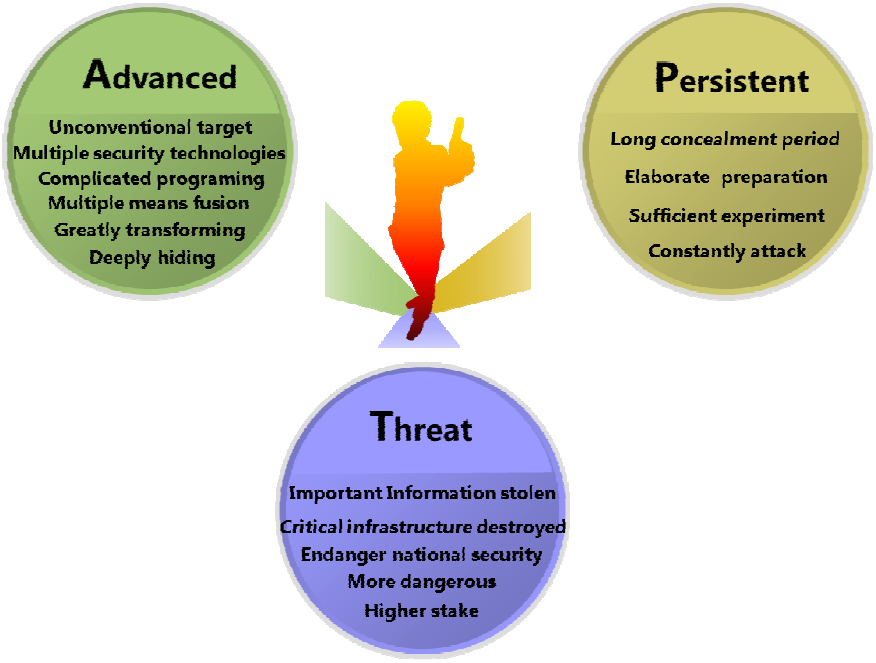

Fig.1. The specific connotation of APT

Since nucleus facilities of Iran waw attacked by Stunex worm virus in July 2010, a lot of APT attacks including Night Dragon, Google Operaion Aurora, RSA SecurID and Shady Rat have happened. The global nerwork warfare on behalf of APT attack weapons has begun a new stage until the Flame virus swept over the Middle East in May 2012 [3]. Considering attack targets of APT are mainly focusing on network infrastructure and key department such as energy, power, finance and national defense, it can endanger security of country politics and economy. It will be meaningful analyzing with typical APT cased and performing pertinence precautionary measures for maintaining security of core cecret information and important industry control system.

Typical APT Attack Cases

Night Dragon Attack. It was found attacking global major energy companies by McAfee in Feb 2011 and its specific attack process is described as follow. Firstly, attacker broke Web server of external network by SQL injection. Secondly, terminals and servers in internal network were scanned with broken Web server. Thirdly, password of terminals and servers in internal network was cracked with brute force. Fourthly, malware including trojans and backdoors were planted, and plenty of secret sensitive files were sent back to attacker. Fifthly, Emial with malware attachment was sent as a top executive and more terminals in internal network would be invaded by inducing emplyee to click the Email.

Google Operation Aurora Attack. Network was permeated for months due to clicking a malicious link in instant message by a Google employee and all kinds of secret system data were stolen. Its specific process is described as follow. Firstly, attacker collected personal information of Google emplyee by social engineering method. Secondly, a Web server hosting photo website was faked by a dynamic DNS provider. So Google employee would be induced dowloading and running malware when he clicked web link receiving from one person he belive. Thirdly, the account password accessing Google server would be stolen by continuous listening after establing connection with terminal of victim within a SSL security tunnel. Fourthly, the Email content information of special Gmail account was stolen continually when attacker succeed in permeating Google Email server taking advantage of account password of the google employee.

RSA SecurID Attack. RSA company affiliating with EMC company was intruded in Mar 2011. As a rusult, part of SecurID technology and customer information were stolen. Several American defense contractors including Lockheed Martin Corporation and Northrop Corporation were attacked leading to important data stolten. Its specific process is described as follow. Firstly, attacker sent two groups of malicious Email to four employees of RSA, and its attachment was excel named 2011 Recruitment plan.xls. Secondly, one employee read this Email and its excel attachment containing new 0Day vulnerability of Adobe Flash. Thirdly, the termial of this employee was panted remote control tool named Poison Ivy and perform task by download instructs from BotNet. Fourthly, attackers left immediately and transformed all data compressed with encrytion by FTP when they were found by RSA. Fifthly, attackers began intruding companies using SecurID after stealing SecurID information.

Shady Rat Attack. It lasted for years and was found by McAfee/Symantec in Aug 2011. It permeated and attack network of global corporations and groups including American government, the United Nations, Red Cross, weapons manufacturers, energy company, financial company, and its number is up to seventy. Its specific process is described as follow. Firstly, attacker collected information of target by social engineering method. Secondly, attackers sent some temptatious Email containing attachment to some typical person of target company. Thirdly, trojan would be planted when victim opened Email and saw the attachment. Fourthly, trojan would connected with remote server and download malicious code. Fifthly, attacker would control terminal of victim by building remote shell connection.

Process of APT Attcak

Tab.1. The comparsions of typical APT permeated methods

Typical APT Cases	Permeating Methods
Night Dragon Attack	SQL Injection, Oday Vulnerability, Password Crack, Malicious Email
Google Operation Aurora	Oday Vulnerability, Malicious Email, Social Engineering
RSA SecurID	Oday Vulnerability, Malicious Email, Social Engineering
Shady Rat	Malicious Email, Social Engineering, Vulnerability Aiming at Excel
Stuxnet	U Disk Ferry, Oday Vulnerability, Social Engineering, Vulnerability Aiming at PLC

Targets of APT attack are usually protected closely and attacked difficultly. The typical target is internal network which has no physical connection with Internet and is protected closely by DMZ isolation. Its representative process is generally permeating outside-in and diverse attack methods, which involves U disk ferry, SQL injection, malicious Email, etc. Oday vulnerability and social engineering are principal methods, which plays a vital role in attack process [4]. Comparsions of typical APT permeated methods are shown as Table 1.

The main process of APT attack consists of three phases such as attack preparation, external penetration and insider attack. It can be shown as Figure 2.

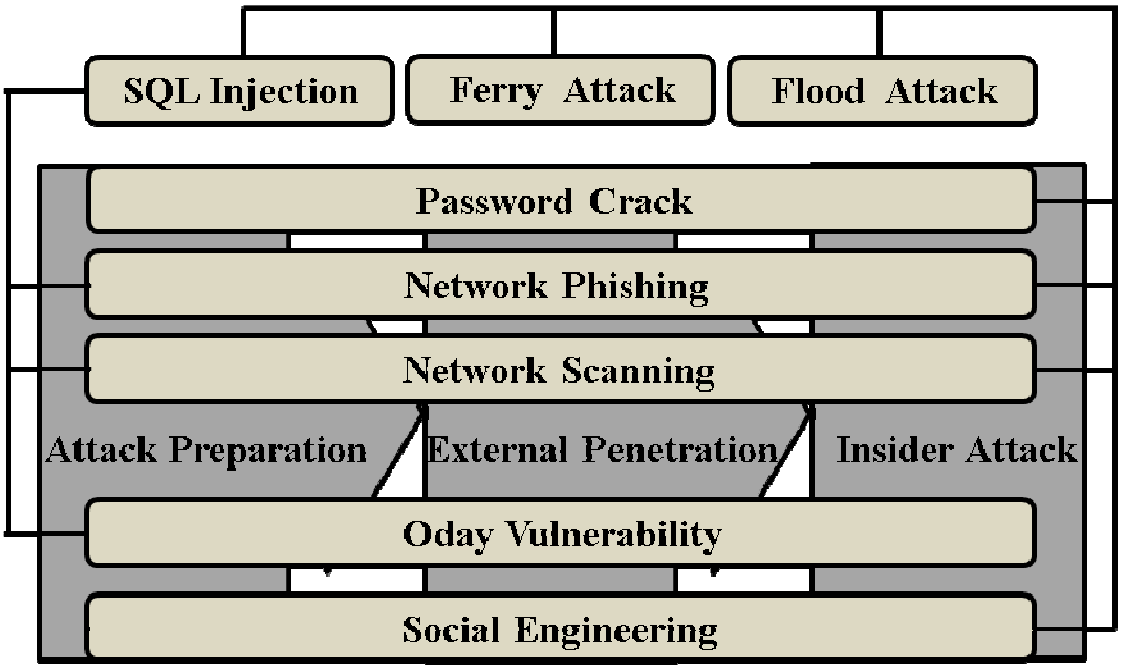

Fig.2. The main process of APT attack

Attack preparation need collect plenty of preparation work in the early after selecting target by attacker. Informaiton of target will be collected and sorted utilizing various technology means including social engineering methods and network phishing. External penetration means permeating and intruding into internal network utilizing various means including remote flood attack, SQL injection and U disk Ferry.

Security Protection of APT attack

As advanced and persistent permeating attack, security danger can't be eliminated by preventing one attack action. Security protection of APT attack must be a long-term and persistent process. Security manager must be on the alert and raise security awareness [5]. The specific security protection measures of APT attack are listed as follow.

Detection of APT Attack. Effective detection is premise for blocking and stopping of APT attack. Multiple dimensional security protection model involved test of technology and analysis-tracing of management should be built in detecting APT attack. It must be able to recognize and analyz unnatural conditions of network and server. So that key actions of APT attack may be captured and overall solution of APT action monitoring could be deduced. Intrusion tracks including network penetration, trojaner plantation and data duplication will be detected no matter how carefully the plan was put forward. Then security action should be put into effect and operation site should be saved. Those suspected infectious terminals should be isolated immediately and inspected in detail.

Response on APT Attack. It depends on effective detection means. More effective countermeasures and higher success rates will be obtained when more information of infected terminals, APT attack means and target information has been collected [6]. Security protection

actions can be put according to predefined protection strategy if APT attack response has been included in emergency plans of information system. Facing with unkown APT attack mans, response methods covering disconnecting with infected terminals, blocking network areas, reconfiguring IDS, locating intrusion and permeating reversely should be adopted.

Prevention of APT Attack. Firstly, prevention should start from users and terminals. Poor security consciousness is important reason for breaking security defence by hacker. As the last defence, terminal must has a certain degree of security protectin capability. Secondly, Control of system operations and network flow must be strengthened. Operations should be allowed in line with security stragegy and malicious operations should be stoped. Finally, system manager should master new security threat and answer unknown security risk actively.

Conclusion

As a new category of network attack method, APT has constituted a huge menace to information security of enterprise and government [7]. Given that APT attack adopted various new technologies and presented some new characteristics including purposiveness，concealment，sustainability and variability, it is hard to protect for personnel of technology and management. The general attack process and technology characteristics are summarized. Some suggestions and opinions on secrutiy protection were also presented. It will provide beneficial reference for protection various unknown APT attack means.

Keywords: data mining, network security, high dimensional data, text clustering.

Abstract. As the Internet is developing fast, network security issues are rising. Data mining technology is applied to the analysis and understanding data, revealing hidden data secret inside knowledge. Especially high dimensional data mining can be used in information security data analyze, making the study of high-dimensional data mining very important. In this paper, traditional data mining is introduced; the concept and core ideas of high dimensional data mining are described, as well as its applications in network security.

Introduction

The rapid development of the Internet brings in a whole bunch of changes to people's life, especially in entertainment and working life, but the openness and security of the Internet is a contradiction. For the sake of a lot of convenience and fun that the Internet brings to us, we have to face the fact that things that are harmful to us are being uncontrolled transmitted, network security issues become increasingly prominent.

For example, users are being spammed, business websites have been hacked by malicious computer programs etc., resulting losses to businesses and users. How to improve network security has become a hot spot of current research.

As an emerging field, many disciplines and methods are involved in data mining[1] .Its core technology has experienced several decades of development, including statistic, nearest neighbors, clustering, decision trees, neural network etc.

Today, these advanced technologies have been put in use in network security, and have achieved good results. For example, network intrusion detection systems based on data mining technology have many advantages over traditional ones.

However, in practice there are still many unresolved issues. One of the most difficult problems is to make the decisions when to use what kind of data mining techniques. In order to be wiser when choosing which data mining technology to use, this paper introduces data mining technology in network security and a variety of data mining techniques applicable occasions.

Data Mining Technology

In recent years, researchers have paid more and more attention to data mining technology in the field of information security. Capable of handling massive amounts of data and easily discovering the hidden information and patterns independently which are subjectively neglected by people are the advantages of data mining technology.

Traditional Data Mining. In the process of information security analysis, we can take advantage of data mining technology to effectively analyze the information, and automatically generate accurate detection model from massive data[2]. Of course, data mining is not simply to build a detection model only, it is a process of knowledge discovery. Knowledge Discovery is iteration consists of the following sequences, including data cleaning, eliminating noise and inconsistent data; data integration, putting together a variety of data sources; data selection, data extraction from data sources which are related to analysis tasks. Data transformation is the process that the data converted into a form suitable for unified mining. Data mining is data mode extraction using intelligent method.

Assessment model is a technique according to certain measure, to identify really meaningful patterns of knowledge. Knowledge representation shows users the mined knowledge in an appropriate way.

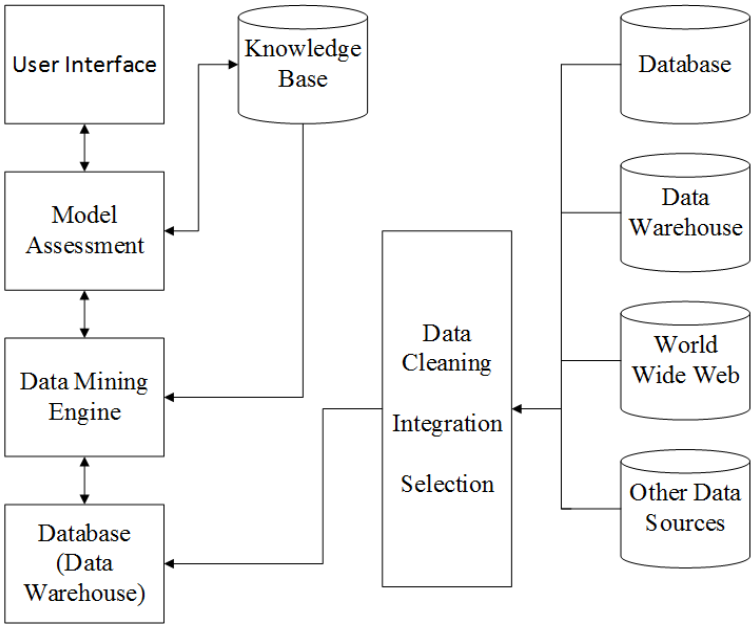

Fig. 1. A typical data mining system components

In the process of knowledge discovery above, data mining is one of the most important steps, and the broader point of view is that: Data mining is the process of discovery of interesting knowledge from large amounts of data which is stored in databases, data warehouses, or other repository. For the reasons above, the typical data mining system has the following main components shown in Fig.1.

Databases, data warehouses, World Wide Web or other information library is a complex set of data sources, which can contain multiple types of repository, where data can be cleaned and integrated.

Database or data warehouse server is used for containing the processed data according to the mining demands of users.

Knowledge base is the domain knowledge from and experts and the users' beliefs, can be used to guide the search mode degree of interest or the assessment of the results. Degree of interest may include additional constraints and thresholds, and meta data.

Data mining engine is a fundamental part of the process, ideally by a set of functional modules for performing characterization, association and correlation analysis, classification, prediction, cluster analysis, outlier analysis and evolution analysis and other tasks. It is capable to describe and predict the two major types of mining according to different needs of users. The so-called descriptive mining refers to the general description of the data; predictive mining is to analyze the existing data inference, predicting future behavior. Specifically, the concept can be divided into descriptions, association rule mining, clustering analysis, classification, anomaly detection and evolutionary analysis. And based on the need to guide the learning process can be divided into data mining methods in: supervised learning and unsupervised learning, the main method of the former is classification, the main method of the latter is cluster analysis method.

Model assessment is the module that interacts with the data mining module, it can be used to filter patterns which have been found, the metrics is the interest threshold. Model assessment can usually be connected together with the data mining module for effective data mining.

User Interface is the module completes the communication between the user and the data mining system , which allows users to interact with the system , to better illustrate the key data mining tasks or queries , and give the user a platform to submit information to help focus. Intermediate results can dig exploratory data mining based on the data. In addition, this component also allows the user to

browse the database, a data warehouse or a data structure model to assess the mining model, to achieve visualization of the model from different angles.

High Dimensional Data Mining. In many application fields of data mining, data is becoming increasingly complex[3]. In fact, various types of transaction data, document data, gene expression data, network communications data can reach dozens, hundreds or thousands of dimensions. If we represent these data into a high dimensional point, the objective world of things can be represented by a collection of high-dimensional data, data mining for that is the high-dimensional data mining problems.

Typical high-dimensional data includes the following:

(l) Shopping basket data: shopping basket data records customer buying behavior for customer relationship management.

Consider using a table to record the customer's once purchase behavior, each row of the table represents a transaction record, in addition to some basic information about the customer , the columns of the table need to record the transaction time, location, transaction method, payment information and promotional information and other items; in addition, you can also breed every kind of goods or services as a column, if customers purchase certain goods or services, then the corresponding columns can be marked or record the quantity or amount of purchase, so that the "shopping basket" of data is a high-dimensional data.

(2) Document data: types of documents typically use vector space model (VSM) to represent. In VSM, each document is represented by a space vector of words.

A typical text mining systems need to process thousands of words, therefore the document data actually have very high dimension. Document data mining specifically includes document classification, text clustering, etc.

(3) Program file data: Program file data is a set of program files to reflect the characteristics of program behavior data, which is the base of data mining computer virus or malware detection system. For example, in Microsoft Windows operating system, the files that records the program API function name calls or a string containing the program files can be used to describe a program, such data typically has thousands of dimensions.

Text Clustering. Text clustering is the most typical application in automatic data classification with high-dimensional data clustering method. A text clustering system is shown in Fig. 2.

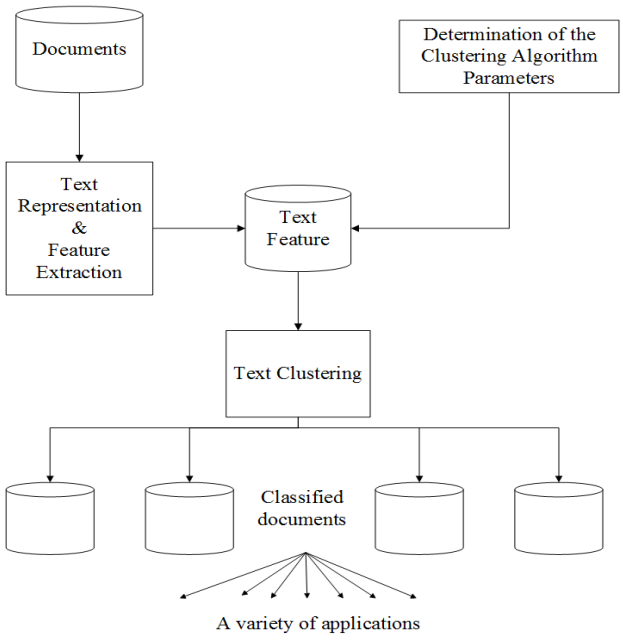

Fig. 2. Structure of a text clustering System

As shown, because the document is unstructured, before text clustering various types of documents need to be converted into structured data. Commonly we use vector space model (VSM)[4] to convert this structured data.

The documents need to be preprocessed when it is represented in VSM (eg: stemming English text, word and POS tagging Chinese texts, stop words filtration, etc.) each document is represented as a vector in word space, which is a high-dimensional sparse space.

VSM-based document clustering also has the typical characteristics of subspace clustering. Clearly, a different set of keywords is different categories of documents, the text subspace clustering subspace clustering features, using local feature weighting method to classify documents at the same time, you can also extract the different document categories there are differences set of keywords.

Network Security

In recent years, with the development of the Internet, network security problems have become more serious[5], and the virus as one of the main issues of information security has become an issue of concern to many researchers.

The Internet is a mixed bag of the world, at the same time a lot of important information, irrelevant information is spread on the Internet, so build information security system is particularly important, including security protocols, computer security operating system security mechanisms (message authentication, data encryption, digital signatures), and the security system, any security vulnerabilities can be a threat to global security. Information is of great significance for specific individuals or group, as a resource, it is universal, shared, and even value-added. Protection of information system or network information resources from various threats is the essence of information security. The typical data mining techniques can be applied to network security projects are anti-spam, intrusion detection and malware detection. .

Some Applications of Data Mining Technology in Network Security

Currently, high-dimensional data mining analysis has been applied in many fields, such as face recognition, voice recognition, the paper recommendation, customer relationship management and web search engines. Following is some application of high-dimensional data mining.

Anti-Spam. A famous anti-spam organization once gave a definition of spam, that junk e-mail should have the following two characteristics: First, uninvited, meaning the user don't request or agree to receive e-mail before; Second, batch , meaning a copy of the e-mail is sent may times in a short period of time to one or more users.

Content-based spam filtering[6] is one of the specific applications of text mining in network security field. Currently, there are two types of spam filtering techniques: content-based and rule-based approach. Rule-based methods include the white list and black list technology, rules -based filtering and content scanning, keyword matching, etc. The downside is that the rules need to manually continue to discover, review and update. It also needs to be considered spam features may change over time and we have to change the rules.

Text content based spam filters get a lot of attention, the basic starting point is regardless of the spam address or other structural part of the change, spam the text content is always different from ordinary email.

Your job will be to stuff and mail
envelopes.You will receive $.25 for each
and every envelope you stuff and mail out.
For example stuff and mail 1000 envelopes
```

Fig. 4. Illustration of spam

There are two kinds of email above. Obviously, Fig. 3 is an email notification of some conference, there is a great difference between the message content of Fig. 4, the message content of Fig. 4 would normally be viewed as spam filters.

Similar to the general text mining system, content-based spam filters typically use VSM Model to structure mail files.

The VSM Model is consisted of the glossary of the mail text, each element of the table is the frequency of words appeared in the corresponding text (which is the simplest form of VSM model) .Various classification methods based on that kind of text representation method, such as decision trees, SVM, etc., are applied to the text-based spam

However, text classification need guidance, it is hard to classify spam with unclear subject. But now application text clustering and subspace clustering technology without guidance based spam classification method has been proven to effectively improve the recognition rate of spam.

Intrusion Detection. Internet is an open environment and sharing of information, security issues is always a severe challenge.

Because the system security vulnerability exists objectively, operating systems, application software, hardware, equipment, etc. security vulnerabilities inevitably exist. Some of the network protocols design exist a number of security risks, which are easily used in hacking web applications.

How to protect network security, prevent network intrusion become an issue of concern. The thought of applying data mining techniques to intrusion detection system is due to increasing amount of network security data issues. The most important feature of clustering based intrusion detection method is no guidance, it can be marked on the audit data were not found new or unknown types of intrusions.

The basic idea of intrusion detection algorithm based on cluster analysis with a different number is from the thought that the difference between invasions and normal behaviors and abnormal behavior patterns should be much larger than the number of acts of intrusion ones[7], so the data set can be divided into different categories, which distinguish between normal and abnormal behavior to detect intrusions. Portnoy first proposed intrusion detection technique based on cluster analysis. Network intrusion detection data is of high dimensional features, we need to use some high-dimensional cluster analysis, for example, using subspace clustering literature to detect hostile access. In Intrusion detection based clustering, outlier is often seen as representative of intrusions which are quite different from normal behavior.

Identification of malware. Computer viruses have serious implications for the normal operation of the computer system and people's daily work and life. With the development of Internet and software technology, the number of computer viruses and attacks is hidden and difficult to prevent. In recent

years, there are about 30 to 100 kinds computer viruses being produced a day, the total number of all types of the virus has reached 100,000 kinds.

At the same time, the concept "computer virus" is also slowly changed, various forms of trojan horses, worms, spyware and backdoor behavior has been difficult to distinguish form "computer virus", we will collectively name the software above as malware.

Currently, in detection and prevention of malware, signature detection is still the main technique. In order to improve the ability of identifying malware, it is crucial to quickly analyze and judge suspected malware or the variant of the malware known, this is malware identification problems.

Using data mining methods for malware auxiliary identification is a good method. Like text clustering, before that we need to convert files into structured data, which is the characteristic of the program file. Through the PE program (Microsoft Windows operating system executable program, including .EXE, .DLL files, etc.) static analysis, using the API function calls to represent their program characteristic is a commonly used method in recent research. Clustering analysis methods can be used to achieve the auxiliary identification of malware.

We can use clustering analysis based on the data files for automatic classification. On the basis of the extracted API call, analyze the program's behavior .Using cluster analysis algorithm for automatic analysis of malware. However, due to frequent variants of malware, and the behavior of the normal software program with "fuzziness" and other factors inherent in these automated analysis tools. There are some false positives and false negatives are to be improved.

Summary

If you Protecting Network information security from damaging is a large, complex work, which need to be fully take into account the diverse data sources. However, if we can excellently make use of data mining techniques in dealing with massive data, the data mining algorithm can automatically dig out effective rules, and can update the rules to improve the system of automation Degrees. But for a perfect system, there are many works to be done, such as: improving data mining algorithms, improving the system's adaptability, improving the timeliness and accuracy of detection systems, etc.

Keywords: E-commerce; Credit Evaluation; Model and Method; Seller Credit; Customer Credit

Abstract. Based on the brief introduction of the credit evaluation system for the primary e-commerce platforms, the advantages and disadvantages of the existing systems were analyzed in details. Moreover, some important problems of e-commerce credit evaluation were systematically discussed, which include the uniform standard of rating scales and marks, the pattern of product rating, the evaluating model and algorithm of sellers and customers credit, etc. A complete credit evaluating model was constructed and an effective credit evaluating method was given. They can be selected as the reference for the practice of credit evaluation for e-commerce.

Introduction

Since there are many characteristics such as the remoteness, the changeability of the trading record, the complexity of the subjects, etc in e-commerce, network transaction maybe faces greater risk than the physical market trading. Usually, objective and accurate credit data can provide strong support for the trading decision and reduce the transacting risk to a certain extent. So both the reliability of the credit model and the practicality of the rating method have an important influence on e-commerce activities [1-4].

In order to overcome the shortcomings in the current systems, a model called SMA (Standard-Model-Algorithm) is established as an effective and objective tool of e-commerce transaction credit evaluation. The following contents are included in SMA: the rating scales and marks, the product rating, the evaluating method of sellers and customers credit, etc.

The Main features of current E-commerce Credit Evaluation System

After a comprehensive analysis of the representative e-commerce service platforms including Amazon, Epinions, BizRate, CNet, eBay, Yahoo and Alibaba, some features of the current transaction credit rating system can be summarized as follows [5-8].

- All of the rating system provides credit information of the trading partners.
- Most of the rating system holds the detailed record of product evaluation results.
- The rating system can timely respond to the request of buyers and quickly generate a list of recommended products for them.
- All the credit information is open and real-time updated. While the computational method of the evaluating indexes is relatively fixed.

On the other hand, there are some limitations in the existing systems in different ways to a certain extent [9-12].

- The credit rating scales are not uniform and the rating marks are not standardized. The credit is divided into five levels in most of the rating systems, but three levels or seven ones are used in other systems. On the other hand, either ‘the pentacle’ or ‘the tick’ or ‘the smiley’ may be selected as the rating marks in different systems.

- The semantics of the rating is vague or ambiguous. In different systems, there are great differences in the corresponding relationship between the semantics, the grade and the mark of the same credit rating. Obviously, this situation is not convenient for credit data sharing
- As one of the most important factors of credit evaluation, the definition of 'Quality of Service' is usually neglected in most system, let alone its measurement method.
- The function relation between credit and time is constructed in a few systems, but other index as the clustering weighted method of the review or the reviewer grade is rarely considered in the system design.
- Overall, qualitative analysis methods are adopted by most systems. While the quantitative analysis ones based on objective data are ignored

The Optimized Model and Method of Credit Evaluation for E-commerce

• Rating Scales and Marks

According to the international practice, the credit is divided into five levels from the 1st to the 5th grade. The grade scores are set in reverse order form, which vary from five points to one point. And also, the corresponding semantics of the classifications can be expressed as excellent, good, moderate, limited and bad respectively. Finally, the related logos are selected from five pentacles to one pentacle. The above contents can be summarized in table 1.

Table1. Five rating scales and its marks

Credit rating	Grade score	Credit semantics	Level logo
1st	5points	Excellent	★★★★★
2nd	4 points	Good	★★★★☆
3rd	3 points	Moderate	★★★☆☆
4th	2 points	Limited	★★☆☆☆
5th	1 point	Bad	★☆☆☆☆

• Rating Model of the Products

Usually, the quantitative calculation is mainly adopted in product rating. A unique first grade index called the overall rating and some secondary indexes are included in this rating scheme. The rating scores of secondary indexes are obtained according to the various attributes of the product, which vary from five points to one point. And also, the overall rating value is drawn by weighted sum of the secondary scores. Moreover, this value can be converted into semantics grade or pentacle logo. This course is detailed shown in table 2.

Table 2.Quantitative rating of the product

<table>
<tr><th colspan="2">Indexes</th><th>Score</th><th>Weight</th><th colspan="2">Grade</th></tr>
<tr><td>First order</td><td>Overall rating</td><td>$y=\sum_{i=1}^{n} w_i x_i$
$0 \le y \le 5$</td><td></td><td>Semantics</td><td>Logo</td></tr>
<tr><td rowspan="3">Second order</td><td>Index 1</td><td>x_1</td><td>w_1</td><td rowspan="3">Semantics</td><td rowspan="3">Logo</td></tr>
<tr><td>……</td><td>……</td><td>……</td></tr>
<tr><td>Index n</td><td>x_n</td><td>w_n</td></tr>
<tr><td colspan="2">Notes</td><td>$x_i \in \{1,2,3,4,5\}$</td><td>$0 \le w_i \le 1$
$\sum_{i=1}^{n} w_i = 1$</td><td colspan="2">The grade is rounded up by the value of the variable y</td></tr>
</table>

As an example, the rating course of 'Furniture Product' is given in table 3. (Equal weight is selected in this example. On the other hand, it is obviously that non-equal weight may be adopted according to the different importance of the secondary indexes)

In a period of time, the cumulative overall rating score of a commodity can be calculated by the formula $\bar{y} = \sum_{j=1}^{m} y_j \big/ m$. Where, the variable m represents the times of product rating. And, y_i stand for each rating scores.

In addition, a qualitative rating for product can be given by the buyers in the form of 'Product Review'. It can be regarded as a necessary complement of the overall rating. Usually, the product review focus on the content does not involve in the quantitative evaluation.

Table 3.The rating course of 'Furniture product'

Indexes		**Score**	**Weight**	**Grade**	**Logo**
First order	Overall rating	4.2		2nd	★★★★☆
Second order	Price	5	0.2	1st	★★★★★
	Function	4	0.2	2nd	★★★★☆
	Material	3	0.2	3rd	★★★☆☆
	Appearance	5	0.2	1st	★★★★★
	Firmness	4	0.2	2nd	★★★★☆

Table 4.The evaluating method of the seller credit

Indexes		**Sub-variables**	**Score**	Weight
First class	Overall rating		$y=\sum_{i=1}^{4} w_i x_i$	
Second class	*Product*	g_1, g_2, g_3	$x_1 = g_1 w_{11} + g_2 w_{12} + g_3 w_{13}$	w_1
	Price	p_1, p_2	$x_2 = p_1 w_{21} + p_2 w_{22}$	w_2
	Delivery	d_1, d_2	$x_3 = d_1 w_{31} + d_2 w_{32}$	w_3
	Quality of service	s_1, s_2, s_3	$x_4 = s_1 w_{41} + s_2 w_{42} + s_3 w_{43}$	w_4

Table 5.The illustrations to sub-variables

Sub-variables	**Semantics**
g_1	The quality of the product
g_2	The integrity of the product
g3	The consistent degree of the produce to the description
p_1	The comparative advantage of the price
p_2	The performance-price ratio
d_1	The delivery of the seller
d_1	The delivery of the logistics company
s_1	The quality of service for the seller
s_2	The quality of service for the logistics company
s_3	The quality of after-sale service

- **The Credit Evaluating Model and Algorithm for the Seller**

1. A single transaction credit evaluation

Generally, the evaluating system is made up of three levels indexes. The first class index is called overall rating of the seller. It is set as the variable T. This variable is regarded as the weighted sum of the four second class indexes. Which include the rating results of the four aspects: the product, the price, the delivery and the quality of service. Moreover, the value of every second class index is supported by several sub-variables. The calculating method of the seller credit is detailed shown in table 4 and the illustrations to sub-variables are listed in table 5.

2. The cumulative transaction credit evaluation

Normally, the reliability of credit scoring can be considered as a decreasing function of the variable for time. So the cumulative credit of the seller will be calculated by the method of weighted average based on all the credit scores in the past time.

In a certain cycle, the evaluating period is usually divided into four categories: x_1, x_2, x_3 and x_4. Where the variables $x_i, i = 1, 2, 3, 4$ are set as the distance from the evaluation time to today. Let the time unit is one day, then the value ranges of x_i can be selected as [0, 30], [30, 90], [90, 180] and [180, +∞] respectively.

Corresponding with the variable x_i, the weighted factors $w_i, i=1,2,3,4$ are taken for 0.50, 0.25, 0.15 and 0.10 respectively. Suppose the credit average of every period is written as $\overline{y}_i, i=1,2,3,4$, then the cumulative transaction credit evaluation of the seller can be drawn by the following formula.

$$\tilde{y}=\sum_{i=1}^{4} w_i \overline{y_i}$$

- **The Credit Evaluating Method of the buyer**

Similarly, a first class index called overall rating of the buyer is set in the evaluating system. It is usually expressed as the function of the five second class indexes including the date of payment, the quality of evaluation, the ratio of evaluation, the quality of review and the ratio of review respectively. The calculating method of the buyer credit is detailed shown in table 6.

Table 6.The rating method of the buyer

Indexes		**Score**	**Weight**
The first class	The overall rating	$y=\sum_{i=1}^{n} w_i x_i$ $0 \le y \le 5$	
The second class	The date of payment	x_1	w_1
	The quality of evaluation	x_2	w_2
	The ratio of evaluation	x_3	w_3
	The quality of review	x_4	w_4
	The ratio of review	x_5	w_5

SMA system of transacting credit evaluation for e-commerce

The model and method of credit evaluation constructed in this paper can be summarized as a schematic diagram in Fig.1.

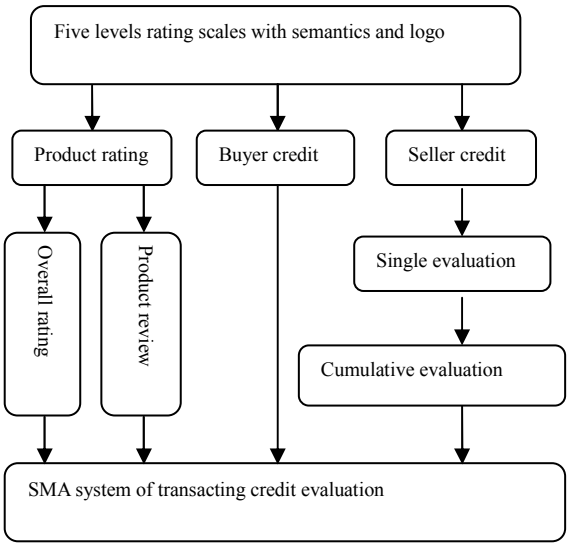

Fig.1. Schematic diagram of SMA

Conclusion

In this paper, some problems of credit evaluation for e-commerce are discussed and a rating system called SMA is designed to improve the traditional credit evaluating methods. Both the quantitative and the qualitative scheme are adopted in this system. It is hoped that SMA can be

selected as a means of credit evaluation in current e-commerce transacting platforms. It should be emphasized that the weighting method may have a great influence on the credit Data. Which method is more suitable for e-business practice will be detailed discussed in another paper.

Research and Implement of Micro-Blog Social Network System Based On Users'Association Analysis

ChenHao

Computer School of Shenzhen Polytechnic, Shenzhen, Guangdong,518055, China

Keywords: Users' association; Micro-blog; Social network system;

Abstract. With the widespread application of web2.0 technology, micro-blog has become an important part of life for many people. A well-designed micro-blog system has the better users' experience and allows users to get the information what they want with high efficiency in the shortest time. After analyzing each of the existing micro-blog systems, we found that the most information of micro-blog is sorted by time. With the users' attention gradually increased, the frequency of message update, its contents appeared homogeneity and repetition, and thus leaded information overload. To solve this problem, this article puts forward a method based on users' association analysis and implements a micro-blog system which presents its contents in priority based on users' interest by way of users' association analysis. It can sort the contents of the micro-blog and show the contents which the user interest in priority.

Introduction

In 2010, the fastest growing of web2.0 application of internet was the micro-blog service in China. After the following SMS, instant messaging, blog, SNS, communication tools and so on, micro-blog relied on its good user experience, and quickly entered the global Internet users' view. Web, which is a small blog can be available for releasing news, its biggest feature is the length of a short post, the diverse ways of post [1]. Micro-blog is so popular, because it is more casual, convenient and instant than other media. There is no need to consider logical rigor. It can use here and here. In addition, user can express their ideas to the public everywhere in any time [2].

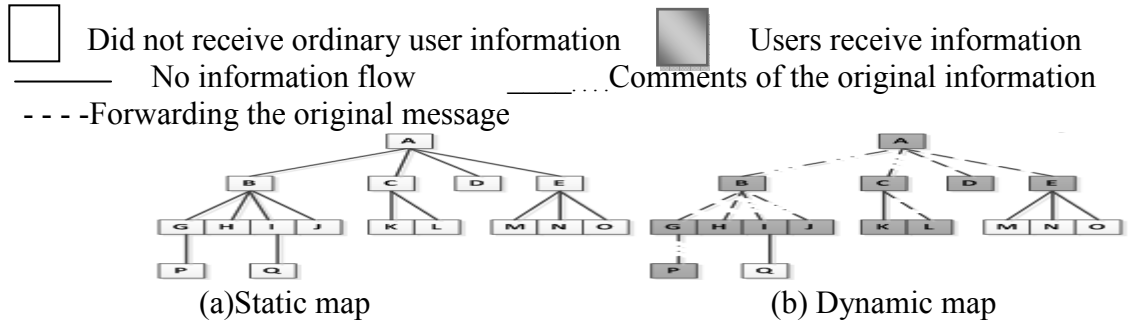
Micro-blog system is a platform that we can share, disseminate and obtain information based on users' association. With the fast transmission of information and the strong fidelity, it can achieve the point transmission and show information [3]. A good micro-blog can be widely disseminated in a similar property circles, at the same people's social needs have been greatly satisfied.

In micro-blog network, users have established close relationship (attention and is concerned) than the forums and other social networks the between the users. Not only established a dynamic relationship between users by forum posts. Dynamic can be understood as information flow. Information can treat the static users' relationship as a track and flow to various users [4]. Therefore, when the micro-blog develops to a certain extent that users' relationship is at the beginning and the information flow is at the back, the relationship shown in Figure 1.

The article combines with the current mainstream micro-blog site, in depth study of the basis of its design and architecture, through the analysis of access to information among users, mining association between the users that designs a user-based association relation and meets social network system key requirements. It is a micro-blog social network system that may show the information which the users interest in priority.

Related work

The first prototype of micro-blog was proposed by Evan Williams in March 2006 in America. It meant the birds' twitter and was extended to the idea for everyone to express their wish and share their desire. The core of the first prototype of micro-blog is in short and random, which is not more than 140 words and tell the others what were you doing [5]. Twitter was fame when it was invented firstly. The annual growth rate of it was reached to 1382％ and its users was over ten million. Moreover, Obama is its loyal users, too.



(a)Static map (b) Dynamic map

Figure 1 Users diagram

In May 2007, Chinas' domestic micro-blog service providers began to appear. From February 2009, the domestic micro-blog has been full of new vitality. Micro-blog sites have on-line continuously and the number of users increases sharply. Micro-blog has become a new feature of the development of internet. In August 2009, Sina micro-blog was on-line and became China's most influential micro-blog. Driven by Sina micro-blog, integrated portal micro-blog, vertical portal micro-blog, news site micro-blog, E-commerce micro-blog, SNS micro-blog, independent micro-blog sites have been established one after another. Even the TV station telecom operators have begun to get involved to micro-blog service [6]. China has really entered into the micro-blog era.

Micro-blog information can spread by means of users' relationship net. Users have their own property, such as stars, media, or grassroots. Users' relationship refers to the micro-blog system that depends on it. And it can excavate the concerned users and the published contents. We can extract the users' property, interest, hobbies and so on. Before the new information arrived, it can sort out the contents combined with the users' property. It can show the micro-blog information that we interest in priority.

Micro-blog user association analysis

Using the correlation theories focus on the number of users, the number of micro-text and are concerned about the number three information analysis, based on the analysis results, the user can calculate the number of targets to increase attention to the behavior of the trend. The correlation coefficient used to indicate the degree of linear relationship between two variables, the Pearson correlation coefficient of the main, Spearman correlation coefficient and correlation coefficient of three kinds of Kendall. Usually Spearman correlation coefficient is calculated as follows:

$$r_s = 1 - \frac{6\sum_{j=1}^{n}(R_j - Q_j)^2}{n(n^2-1)} \quad (1)$$

Where, R_j and Q_j are the j-th rank values of two variables. Believed, | r | closer to 1, the higher the degree of linear correlation; | r | the closer to 0, the lower the degree of linear correlation. $r > 0$, which means that two variables correlated; $r < 0$, which means that negative correlation of two variables; $r = 0$, which means that two uncorrelated variables.

The number of micro-text and concerned are an important factor to measure activity level of micro-blog. While the number of being concerned is an important factor to measure users in the micro-blog. Users are usually most concerned about the factor. Learn the relationship between them, it is good to understand users' behavior and determine the level of activity of the user. In order to eliminate the impact of celebrity, we should remove the celebrity and the user to be concerned about the number, concerned about the number and the number of any one of the micro-text which has no user. Then use SPSS software to the number of micro-text and concern as the control variable number of partial correlation analysis, the specific results as shown in Table 1 and Table 2.

The number of concerned (NOC) is used to a person who pays attention to others' Micro-blog. The number of being concerned (NOBC) is used to a person who is followed by others.

Table 1 The number of micro-text for the control variables and correlation coefficients of the NOC and the NOBC

Control variables	Variable	Parameter category	NOBC	NOC
The number of micro-text	NOBC	The correlation coefficient	1.000	-0.017
		Associated probabilities	0.000	0.376
		Quantity	0.000	2854
	NOC	The correlation coefficient	-0.017	1.000
		Associated probabilities	0.376	0.000
		Quantity	2836	0.000

Table 2 The NOC for the control variables and correlation coefficients of the NOBC and the number of micro-text.

Control variables	Variable	Parameter category	NOBC	NOC
NOC	NOBC	The correlation coefficient	1.000	0.074
		Associated probabilities	0.000	0.000
		Quantity	0.000	2854
	The number of micro-text	The correlation coefficient	0.074	1.000
		Associated probabilities	0.000	0.000
		Quantity	2836	0.000

As can be seen from Table 1,removing the effect of the micro-text, the correlation coefficient concerned about the number and the number of attention is - .017, 376, related to the probability is 0.376, indicating that there is no relations between the two. As can be seen from Table 2, in the removal of several concerns, the correlation coefficient concerned about the number of micro-text and numbers becomes into 0.074, indicating that there is no relations between the two basic.

Using SPSS software calculates Spearman correlation analysis of relations between any two, the results are shown in Table 3.

Table 3 Correlation coefficients of the NOBC, the NOC and the number of micro-text

The correlation coefficient	Variable	Parameter Type	NOBC	NOC	The number of micro-text
Spearman	NOBC	The correlation coefficient	1.000	0.309	0.569
		Associated probabilities	0.000	0.000	0.000
		Quantity	2785	2785	2785
		The correlation coefficient	0.309	1.000	0.437
	NOC	Associated probabilities	0.000	0.000	0.000

		Quantity	2785	2785	2785
		The correlation coefficient	0.569	0.437	1.000
		Associated probabilities	0.000	0.000	0.000
	The number of micro-text	Quantity	2785	2785	2785

As can be seen from Table 3, the correlation coefficient concerned about the number of concerns with the number is 0.309, the relevant probability is 0.000, indicating that there is a certain correlation between the two. Combined analysis Table1 shows that when the number of affected by the micro-text, it is concerned about the existence of relations between the number and the number of attention. If the users release micro-text frequently, there will be more people to concern him. Thus increase the number to be concerned about. With the increasing number of fans, it is easy to make the users to concern others. Otherwise, it is on the contrary. Is concerned about the number and the number of micro-text correlation coefficient is 0.596, the relevant probability is 0.000, showing a moderate positive correlation. Table 2 combined analysis shows that when the number of affected concern, there is a relationship between the number of attention and concern number. That is, if the user paid little attention to other people, even if slightly more users to publish text, others pay attention to him nor the General Assembly.

Users realize the associated

In micro-blog system, each user has two roles there, followers and those who are concerned. It is important how to deal with the relationship between users and let users′information effectively circulate between the two roles.

In Figure 2, it is a conceptual model including users (in the conceptual model entity name for Users) micro-blog information (in the conceptual model entity name for Messages) and customer relationship (in the conceptual model entity name for Relations). For example, user A add the concerned operation to user B. Then it can conduct a piece of corresponding data from A to B, which indicates that A concerns to B. When A gets the new information, then we can find out the corresponding relation with A. Then we can connect to the micro-blog information through a database table relations and get their message queue.

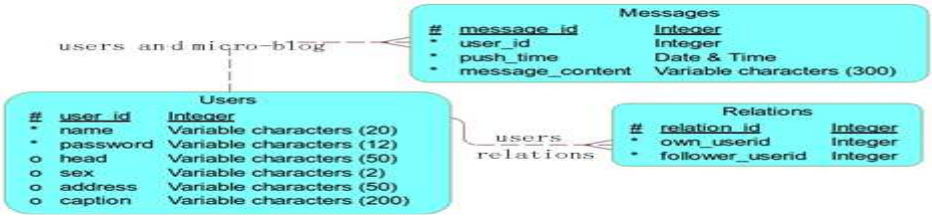


Figure 2 Users, micro-blog conceptual model diagrams and relationships

A user association model is important for users association. We can generalize the user′s module by the user's interests and behavior information. Firstly, we should obtain all the published micro-blog of the users, then analysis the features of the information and describe it in the form of natural language. We can conduct word processing, removing the word and forming the keyword list. We should give appropriate weight to each keyword to form micro-blog feature table. Micro-blog features reflect the characteristics of each user's interests, hobbies, habits and behavior. On the basis of the relationship between the users, through micro-blog characteristics associated table, we can get the user association model. It can reflect the common point of interest between the users. The system is the basis for this analysis of the new micro-blog messages, allowing users to more timely access to the message might be interested.

System Design and Implementation

The system server is designed mainly for using ASP.NET technology. ASP.NET is built on HTTP protocol. It is full of using HTTP commands and strategies to establish bi-directional communication and collaboration browser to server (B / S). It is the biggest difference with other Web development technologies that made it an abstract programming model (Abstract Programming Model), that is, the Web Forms model [7]. Therefore, we can easily use rich controls on the server side development.

Open the website system, users enter the login screen and import a nickname and a password and then click on the login. Otherwise you cannot get in it. When entering the home page, the users concerned people have micro-blog updated and presented at this time. On home page, people can check the concerned people or un-follow. People can also check who concern me. If not, he can concerns them. We can publish the micro-blog or delete the micro-blog. Setting basic personal information, saved to the database, if not saved directly back home; logout login, delete the user's login status, back to the login page.

Conclusion

This system can excavate associations between users and predict new Twitter users ' level of interest and reorder the new micro-blog through the Twitter data for analysis. Interface is simple and clear navigation buttons improve the system efficiency data lookup and data updates, so micro-blog home is more convenient to use and has a strong fault tolerance and security.

We need to further improve the place in the system development, such as the complexity of the algorithm which will lead to lower home micro-blog update efficiency. In the next study, the manner contemplated by calling interface realizes the system with the current mainstream micro-blog system (Sina micro-blog etc.) and achieve information sharing of data. Meanwhile, micro-blog system can also be ported to mobile devices user at any time through the use of smart mobile terminals micro-blog system.

Keywords: Sentence Alignment; Chinese; Uyghur

Abstract. This paper introduces a new method to Chinese-Uyghur sentence alignment, in which a two-step procedure is applied. In the first step, multiple clues such as proper names, technical terms, numbers, punctuation marks, location information and length information are used to generate anchor sentences that satisfy some conditions. In the second step, texts are divided into several segments by using the anchor sentences as boundaries, and then the sentences in each segment are aligned by using a length-based approach. By applying the segmentation technique, the method avoids complex computation and error spreading. Experimental result shows that the accuracy of the method is 95.2% on the average for multi-domain texts.

Introduction

For parallel corpora, the most important annotation is alignment, especially sentence alignment, which is a minimal and essential requirement for a parallel corpus. Aligning Chinese-Uyghur parallel texts at the sentence level, however, is already very difficult because of the considerable differences in writing systems and syntactic structures of the two languages. Chinese uses Chinese characters as its writing system while Uyghur uses alphabetic character. Chinese is an analytic language that has SVO word order. In contrast, Uyghur is a suffixing and agglutinative language that has SOV word order.

A number of alignment techniques have been proposed for other language pairs, varying from statistical methods to lexical methods. There are basically three kinds of approaches on sentence alignment: the length-based approach [1][2], the lexical approach [3], and the combination of the two [4]. However, the method does not capture enough word correspondences for structurally different languages such as Chinese and Uyghur.

This paper introduces a new method to Chinese-Uyghur sentence alignment, in which a two-step procedure is applied. In the first step, multiple clues such as proper names, technical terms, numbers, punctuation marks, location information and length information are used to generate anchor sentences that satisfy some conditions. In the second step, texts are divided into several segments by using the anchor sentences as boundaries, and then the sentences in each segment are aligned by using a length-based approach.

An Overview of the Alignment Method

Our method is similar to Wu's [5] in that it uses both sentence length and lexical information. But in our method, some clues such as proper names, technical terms, numbers, and punctuation marks are used to find anchor sentences. Our method is similar to Simard's [7] in that it uses cognates or anchors for sentence alignment. But in our method, length information and anchors are used at different stages of sentence alignment. Our method is similar to Melamed's [6] in that it uses a bi-text mapping technique to locate anchor points, but in our method, sentences are used as anchor points instead of words or characters. A segmentation technique that splits the text into several sections is also introduced to improve the length-based approach.

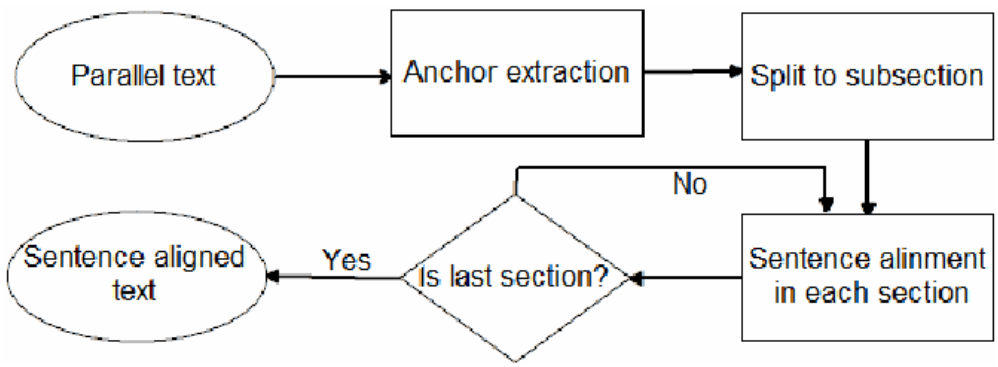

Fig.1. Flowchart of Chinese-Uyghur sentence alignment

As we can see from Fig.1, a two-step procedure is applied to sentence alignment. In the first step, some (1:1) sentence pairs, called anchor sentences, are extracted by using multiple clues. The anchor sentence extraction procedure, as a key part of whole method, will be explained in the following section. In the second step, texts are divided into several segments (subsections) by using these anchors sentences as separator, and then all sentences in each segment are aligned by using a length-based approach.

Anchor Sentence Extractions

3.1 Anchor Sentence

In a parallel corpus, the anchor sentences are specific (1:1) sentence pairs that are strongly correlated and that satisfy some conditions. All such sentence pairs which were extracted from bilingual texts during the first step are seen as anchor sentences. The goal of anchor sentence extraction is to divide the source text and the target text into one-to-one smaller segments. And using the segmentation technique, we attempt to improve the length-based sentence alignment procedure. Sentence alignment tends to be better with shorter segments and, consequently, better sentence alignments are obtained.

For anchor sentence extraction, we applied a bitext mapping technique. A bitext map is a set of pairs (x, y), where x and y refer to precise locations in the first and second texts respectively, with the intention of denoting portions of the texts that correspond to one another [7]. However, we used a bitext map of sentence pairs instead of words or characters to point out the correspondences between these anchor sentences.

In the bitext map, the horizontal axis denotes the sentence number in the Uyghur text, and the vertical axis denotes the sentence number in the Chinese text. The anchor sentences, which are shown as anchor points in the bitext map, can be characterized by three properties:

- **Injectivity:** No two anchor points in a bitext map can have the same x or y coordinates.
- **Linearity:** Anchor points tend to line up straight. In other words, all anchor points are to appear around a straight line.
- **Low variance of slope**: The slope of the anchor points is rarely much different from the bitext slope.

3.2 Algorithm Description

In our anchor sentence extraction algorithm, a three-step process is applied to extract anchor sentences. In other words, the search for each anchor sentence pairs alternates between the following three steps: generation, correction and recognition.

1) Generation

In this step, the search for an anchor sentence begins in a small search rectangle in the bitext map, its diagonal is parallel to the main diagonal. The algorithm generates candidate anchor sentence points within a search rectangle. We define a search rectangle as follows: Rectangle($x,y; x+3, y+3$) in which x is last anchor point(x) in Uyghur and y is last anchor point(y)in Chinese. The first search rectangle is anchored at the origin of the bitext map where x=0, y=0.Subsequent search rectangles are anchored at the previously found points. If no candidate points are found, the search rectangle is

proportionally expanded by the minimum possible amount, and the generation cycle is repeated. The rectangle keeps expanding until at least one acceptable point is found. Three kinds of information such as sentence length, location information and lexical information are used to generate anchor points. Sentence pairs that satisfy the following three conditions are added to the candidate anchor sentence array.

(1)Sentence length ratio

The sentence length ratio is also a very good indication of the alignment of a sentence pair. In our method, sentence pair *P(C,U)* would be candidate anchor sentences, if

$$LenRatio(C,U) \in [MinLenRatio,\ MaxLenRatio] \quad (1)$$

In Eq.1, *MinLenRatio* and *MaxLenRatio* are calculated by using Eq.2

$$MaxLenRatio = TC + A/(L_c + B),\ MinLenRatio = TC - A(L_c + B) \quad (2)$$

$$TC = (C + Len(C)/Len(U))/2 \quad (3)$$

The constant *C* is the expected number of Chinese characters per Uyghur word and *C =2.01*. *TC* is the weighted value when taking whole text size into account, the constants *A=10, B=14*.

(2) Matching score

The matching score is calculated according to the matching degree of clues that explained in subsection 3.3. If the matching score of a sentence pair is above the threshold (we set the threshold = 1.1), it is considered as a candidate anchor sentence. By applying this condition, we reject some sentence pairs with a matching score smaller than the threshold.

(3) Maximum angle deviation (MAD)

According to the properties of the anchor sentences, the slope of the anchor points should not be much different from the bitext slope. So some sentence pairs are rejected by setting a maximum angle deviation. The angle of each anchor point's least-squares line is compared to the arc tangent of the bitext slope. The anchor point is rejected if the difference exceeds the maximum angle deviation threshold (MAD=3). The angle between the least-squares line and the bitext slope is calculated according to the Eq.4

$$\theta = \arctan\left(\frac{|A - B|}{1 + A * B}\right) \quad (4)$$

In Eq.4, A is the slope of the least-squares line, B is the bitext map slope. This filtering process generates anchor sentences with higher accuracy; however, it causes errors in some cases. So, we introduced another correction procedure in order to reject some wrongly aligned sentence pairs.

2) Correction

In this step, some candidate sentences that shouldn't be anchor sentences are eliminated according to characteristics of anchor sentences. Firstly, the algorithm checks if there are any conflicts between anchor points. The injective property of anchor sentences implies that whenever two anchor points overlap in the x or y axis, but are not identical in the region of overlap, then one of the points must be wrong. To resolve such conflicts, we employed a lookup method to eliminate conflicting points. Secondly, length ratios of corresponding segments divided by candidate anchor sentences are calculated according to a similar formula in Eq.2 in order to reject wrongly aligned anchor points.

3) Recognition

A number of candidate anchor sentences can be obtained in a certain search region during application of the above two steps. For anchor sentence alignment, accuracy is more important than recall rate. So it is essential to introduce a recognition step in order to achieve higher accuracy by eliminating some unlikely anchor sentences. In the recognition step, one best anchor sentence pair is selected from candidate anchor sentences according to two parameters: matching score and length similarity. The anchor selection algorithm gives a score to each proposed sentence pair during the recognition phase, and finds the alignment with the largest sum of scores. A parameter estimation method is described in the following section.

3.3 Parameter Estimation

(1)Matching Score

As previous works suggest [4][5], lexical information is critical for sentence alignment, especially for finding anchor points. It is well known that some proper names and technical terms have transliteration or literal translation in many languages; numbers and punctuations appear in the same or similar forms in both source text and translated text. In a parallel text, for instance, if a sentence contains a question mark, it is likely to be aligned to a sentence that also contains this mark, which can be a strong clue for sentence alignment. This is also true for Chinese-Uyghur translations. However, in our method, these clues are not used to align all sentences, but to estimate matching scores and to find the best anchor sentences. We used multiple clues such as proper names, technical terms, punctuation marks and numbers. In most cases, proper names, including person names, location names, organization names, and technical terms have unique translations that will be matched easily. But, the problem is that person names and technical terms are often unknown words. How to identify them is a difficult problem. In our case, we first collected some popular proper names and some most frequent technical terms into a small lexicon that we call key lexicon. More than 6000 words are included in the key lexicon at present. Then, a very simple searching method is applied to match corresponding words (items).

In addition, punctuation marks, including other symbols (e.g. #$%&), are the most obvious clues in Chinese and Uyghur translation. The correlation between Chinese and Uyghur punctuations is extremely high. For punctuation and numbers, no external resources but some rules are applied to estimate the matching degree of these clues.

$$MatchScore(i,j) = 1 - \frac{(x-y)^2}{(x+y)^2} \tag{5}$$

In Eq.5, x is the total number of words (symbols), and y is the matched number of x. The matching scores are calculated according to the average number of matched clues. In other words, the more the matched proper names, technical terms, punctuation and numbers, the higher the matching score.

(2)Length Similarity

Length similarity is a score that reflects the similarity between the length ratio of the current sentence pair and the expected length ratio. The following formula is applied to calculate the length similarity of a proposed sentence pair (C_i, U_j):

$$LenSimilar(C_i,U_j) = \frac{\left|Len(C_i)/Len(U_j) - TC\right|}{TC} * WL \tag{6}$$

TC is the value weighted by the whole text size that is obtained from Eq.3. The sentence length ratio is not stable when a Chinese sentence is shorter than 10 characters. So it is necessary to add WF to obtain more accurate result. Hereby $StableLen=10$, $a=0.5$ and WF is calculated as following:

If $Len(C_i) \le StableLen$, then $WF = a * Len(C_i)/StableLen$, else $WF = 1$.

Length Based Sentence Alignment

According to previous work [1][2], length-based approaches are simple and can achieve good performance for different language pairs. Because of the simplicity, many later researchers integrated this method to their sentence alignment methods. We also applied the length-based approach to the second step of sentence alignment.

4.1 Measuring Length in Words and Characters

Uyghur is an alphabetic language while Chinese is a non-alphabetic language. Therefore, it is a difficult problem to select the best length measuring model. In general, a Chinese sentence does not have word boundary information, so one way to define Chinese sentence length is to count the number of characters in a sentence. Another way is to count how many words are in a sentence after word segmentation. For Uyghur sentences, we can similarly define the length by the number of characters or words. In our case, we examined three possible length models described in the following Table 1.

The mean sentence length ratios, variances and correlation coefficients for each of the length models are calculated from a Chinese-Uyghur corpus of 988 sentence pairs. Statistics of the three sentence length models are shown in Table 1.

Table 1: Statistics on three different length models

Method	Description	Mean	Variance	Correlation
L1	Chinese character to Uygur character	3.99	0.71	0.976
L2	Chinese word to Uyghur word	1.07	0.23	0.953
L3	Chinese character to Uyghur word	2.01	0.21	0.978

In general, the smaller the variance, the better the sentence length model should be. From Table 1, we can see that the character-based length ratio model (*L1*) has significantly larger variance (0.71) than the other two models (*L2: 0.23, L3: 0.21*). This means L1 is not as reliable as *L2* and *L3*. Both *L2* and *L3* have similar variance, but *L3* is better than *L2* with regard to the correlation coefficient, which indicates that sentence lengths have higher correlation if the lengths of Chinese and Uyghur texts are measured in characters and words, respectively. A regression analysis of the three models also proved this result. So we applied the *L3* model to the length ratio examination and length based sentence alignment.

4.2 Preliminary Statistics for the Length-based Method

A length-based sentence alignment program is based on a very simple statistical model of sentence lengths. The model makes use of the fact that longer sentences in one language tend to be translated into longer sentences in the other language, and that shorter sentences tend to be translated into shorter sentences. A probabilistic score is assigned to each pair of proposed sentence pairs, based on the ratio of lengths of the two sentences and the variance of this ratio. This probabilistic score is used in a dynamic programming framework in order to find the maximum likelihood alignment of sentences. The parameters C and S^2 are used for likelihood estimation. C is the expected number of Chinese characters per Uyghur words. The parameters C and S^2 are determined empirically from a hand aligned parallel corpus of multi-domain texts. According to our statistical results, we have $C=2.01$ and $S^2=3.24$.

From the above statistical results, it is clear that the correlation between the length of a Chinese sentence in characters and the length of its Uyghur translation sentence in words is extremely high. This high correlation suggests that length might be a strong clue for sentence alignment. In our cases, we applied the length-based approach to in each segments divided by anchor sentence.

Experimental Results

5.1 Test Corpus

In our experiment, we randomly selected ten texts (total 1483 sentence pairs) from Xinjiang University's Chinese-Uyghur Parallel Corpus as our testing corpus. The texts are come from five domains: fiction, law (legal) texts, official documents, scientific texts and news.

5.2 Results

Firstly, we aligned sentences by using two approaches: a length-based algorithm and our method that using multiple clues. Then we manually checked the alignment results for errors and calculated precision and recall rate.

Table 3: Experimental results

Method	Fiction	Law	Official	science	News	Average
Length- based(Accuracy)	88.5	98.6	97.6	88	89.3	92.5
Length- based(Recall Rate)	87.2	98.1	96.8	88.9	87.6	92.0
Our method(Accuracy)	92.5	100	99.2	90.3	93.5	95.2
Our method (Recall Rate)	92.5	100	98.4	91.3	95.3	95.1

As we can see from Table3, Experimental results show that our method yields higher accuracy than the purely length based approach. The precision of the method is 95.2% on the average for Chinese-Uyghur sentence alignment in multi-domain texts. This is 2.7% higher than that of a purely

length-based approach. We also analyzed all errors of sentence alignment in order to find reasons and solutions.

Conclusions

We have developed a very effective sentence alignment method based on multiple clues. In our method, firstly, anchor sentences are extracted from parallel texts to sentence align by using proper names, technical terms, numbers, punctuation marks, location information and length information; secondly, whole texts are divided into small segments by using anchor sentence points; finally, sentences in each small segment are aligned by using a length-based approach. We have implemented the method on the parallel Chinese-Uyghur corpus. Experimental results show that the precision rate of the method is 2.7% higher than that of a purely length-based approach.

E-commerce personalized recommendation

Yan Zhang

School of economics and management ,Xinxiang university, Henan, China

Email: 837457026@qq.com

Keywords: E-commerce; recommendation; personalized system

Abstract: With the rapid development of electronic commerce, the problem of "information overload" leads to the difficulty that user can't search the required goods effectively , personalized recommendation technology has been applied in e-commerce and popularization. By using the method of qualitative analysis of the current e-commerce site, the paper compare the information retrieval, association rule, content-based filtering and collaborative filtering four main recommendation technologies and analysis the advantages and disadvantages in the application layer, the recommendation technologies are introduced to review e-commerce research hot topic in the field of personalized recommendation, and analysis the current domestic e-commerce personalized recommendation theory research and application status, finally propose the challenges faced by e-commerce personalized recommendation domain.

1 Introduction

The rapid development of e-commerce not only makes the enterprise to save the traditional mana gement mode of the necessary physical investment costs, but also eliminates the traditional store dis play space constraints, gives shoppers a huge counter (also is infinite) goods[1].But because the cust omer can't skim all of the goods through the small computer screen in a short time, and lacking sale s promotion personnel guide carefully, so that users face "information overload". Information overlo ad refers to the commodity information web site to provide users with too much, cause it is difficult to quickly find needed goods, so a user could get tired until losing interest in shopping and leave. Th ee-commerce sites is facing a serious problem: How the user browsing the web site will be suitable f or the users of the goods to him or her, to overcome the adverse effects of information overload, ther eby contributing to more deals in order to increase enterprise sales. At present, information retrieval, association rules, based on the content filtering, and collaborative filtering has been widely used in t he electronic commerce recommendation system. The four kinds of technologies have achieved a ce rtain degree of user oriented personalized recommendation, but it also has some deficiencies. In this context, recommendation system came into being which is according to the user's interests, recomme nd in line with the object of user interests, also known as the personalized recommendation system.

According to the characteristics of the recommended object, at present there are two main types of recommendation system, an object is recommended Web search system, mainly USES the metho d and technology of Web data mining, for users to recommend conforms to the interests of Web pag e, such as Google, etc. Another is online shopping environment for recommended products personal ized recommendation system, referring users to conform to the interests of commodities, such as boo ks, audio and video, etc. Says the recommend system for e-commerce personalized recommender sy stems, hereinafter referred to as e-commerce recommendation system[2].

2 Introduction to e-commerce recommendation system

In this research, we considered only content-based, collaborative filtering, and hybrid approaches that can be implemented by automatic techniques(but not knowledge engineering). By choosing different types of links to use in a recommendation generation process, content-based, collaborative, and

hybrid approaches can be performed using our model. If only product information is used, which means only links in the product layer are activated, it is a content-based approach. If customer-layer and interlayer links are activated, it is a collaborative approach. If all links are activated, it becomes a hybrid approach. The model is flexible because different combinations of links can be activated at run time. For example, we can choose to use product description and price to form product similarity, use demographic data to form customer similarity, and use customers' ratings and purchase history to form interlayer links. The representation can even be personalized for each customer by using a customized weighting scheme. For example, if a customer relies more on the collaborative recommendation, we can assign higher weights to interlayer links and customer-layer links. If the customer is more price-driven, we can assign higher weights to the price information of the product when computing the similarity between products [3].

Recommendation Methods for the Graph Model

Different recommendation methods can be developed based on our model. By viewing the recommendation process as a graph search, we use our model to generate recommendations by finding nodes that have high associations with the starting nodes. Many recommendation methods can be developed based on this graph view. We developed three recommendation methods that covered a wide range of methods being used in the field. For each method, we also describe how collaborative, content-based, and hybrid recommendation approaches can be performed. The direct retrieval method generates recommendations by retrieving products similar to the target customer's previous purchases and products purchased by customers similar to the target customer. It covers most of the recommendation methods that form neighborhoods of customers or products. For content-based recommendation, products that are similar to the target customer's previous purchases are retrieved as recommendations. This situation is similar to document retrieval, in which documents similar to the input queries are retrieved. For collaborative recommendation, a list of customers similar to the target customer is first obtained. Then, similarities can be traced through customer-layer links or through interlayer links from the target customer's previous purchases. In other words, similar customers are those who are demographically similar to the target customer or those who bought the same books as the target customer. The products that are linked to this set of similar customers are retrieved as the collaborative recommendation for the target customer. The hybrid recommendation is obtained by combining the recommendation results from the two approaches described above as shown in Fig1

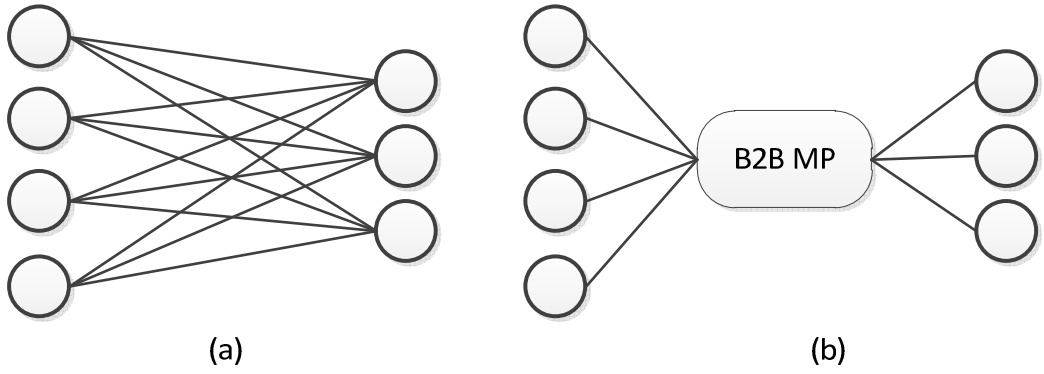

Fig .1 Recommendation system

Recommendation technology

(1)Content- based recommendation It is the continuation and development of the information filtering technology, features related to the project or object by attribute to define. System based on the characteristics of the evaluation objects to learn the user's interest, and to predict the degree of match project according to the user data to recommend, such as newsgroups filtration system[4].

(2)Demographic based recommendation Recommendation system based on users' personal attributes to the user classification, based on class again to recommend classes of users, users are not required to have a history data, and the collaborative filtering and content-based recommendation technology needs to be.
(3) Utility- based recommendation It is calculated according to the utility of users to use the project, the core problem is how to create the utility function for each user, and consider the product attributes, such as providers of reliability and availability of the product and so on.
(4)Know ledge- based recommendation To some extent may be regarded as a kind of reasoning technology, the method has the obvious difference due to different knowledge used in.
(5)Association rule based recommendation Based on association rules, already bought goods as the rules header, recommend object as rules. The association rules are the bottleneck of the algorithm, which are found the key and most time consuming. But can be done offline, name of commodity synonymity problem is also a difficulty of association rules.
(6)Content-based filtering Content-based filtering have many similarities in terms of technology and information retrieval, the difference is that it meets the user's information needs for a long time. Based on content filter for each user to establish a user description , record the contents of the user's likes and dislikes. Then comparing with the content of the project(such as goods, Web page, movies, music, etc.)The similarity of higher project recommended to the user, thus improve the scalability of recommend, and can better explain the recommendation results. Users can describe through the system to the user likes to machine learning to get the content of the project, or by the user's query, questionnaire feedback, etc. Based on the content filtering system such as LIBRA [5].
(7)Collaborative filtering recommendation Collaborative filtering recommendation is one of the most studied the personalized recommendation technology, it based on the recommendations from the neighbor user data to get the target users, recommended by the high degree of personalized collaborative filtering is based on the content to overcome the disadvantages of filters, such as Gold - berg is called collaborative filtering is proposed. The working mechanisms of content-based filtering and collaborative filtering is shown in figure 1.Collaborative filtering according to the target users with similar interests and preferences of other users of certain information to determine whether the information on the target user value, and then decide whether to recommend this information to target users, so as to relieve the information overload. The advantage of the collaborative filtering is to do not need to consider the recommended content of the project, so will not only filter object expanded to all types of resources, and realize the novelty is recommended. To be widely used in the electronic commerce recommendation systems, one of the most successful recommendation algorithm[6].

Recommendation Comments

Recommendation is also recommended, an important problem in the field of overall recommendation can have two kinds of methods: One is the on-line evaluation, another is the line evaluation. Online evaluation is online survey the user evaluation of recommendation system. K.Sw earing enthe recommendation system of evaluation and to recommend your friends compared the experimental results show that the friend's recommendation is often better than recommended recommendation system, recommendation system gives recommendations than friends recommended updates, and identify the key factors for several of the recommended design. Offline evaluation with a set of known data to evaluate the performance of the recommendation system, now generally adopt the digital equipment corporation system research center to provide a special experiment database, the library is a collection of 1996 ~ 2013, a total of 72916 users to 1628 films of 245667618 projects value assessment information, and evaluation analysis using discrete (0, 2, 4, 6, 8, 10),which can be downloaded from the company. Measure generally USES predictive value and the actual and estimated values of the average absolute error, Top - N recommend quality measure generally USES the standard, the evaluation system of information retrieval with accuracy, precision and recall rate (recall), measured accuracy and recall rate to a certain extent, is a pair of contradictory indicators, relatively high accuracy low recall rate. In order to balance the two, usually adopts the comprehensive evaluation index F- measure, in order to control the accuracy and recall rate of preference, E -

measurer index is introduced. A typical experiment database offline Each Movie evaluate all recommendation algorithm is not necessarily correct, especially when considering the date and time, use offline evaluation is not very good for starting from customer satisfaction to evaluate the efficacy of the recommendation.

3 Conclusion

Recommender systems have been applied in different applications to deal with product information overload and to help locate useful information. Their data representations usually are tailored for their specific problems and hence are not flexible enough for use in other applications. In this article, we have described a generic graph model for product recommendation. Customers, products, and transactions were modeled in an extended two-layer graph. To demonstrate the comprehensiveness and flexibility of this model, we experimented with three methods (direct retrieval, association mining, high-degree association retrieval) of making recommendations using three approaches (content-based, collaborative, hybrid). Evaluation results showed that a hybrid recommendation approach achieved better performance than the collaborative approach or the content-based approach. However, the high-degree association method did not perform significantly better than the association mining method or the direct retrieval method because of the high density of the data set we used. We believe that our model is flexible because it can represent different combinations of product, customer, and transaction information and it has the potential to accommodate many graph search techniques for making recommendations. To further validate the current experimental results, we will extend the evaluation study to include frequently used recommendation data sets and directly compare our proposed graph-model-based approaches with approaches employed in previous studies.Other future work includes the use of other graph search algorithms as well as other data mining techniques, the use of a sparse data set to further test the strength of the high-degree association retrieval method and a completesubject evaluation on the usability of our system.

Keywords: Cloud Security; Access Control; Information Security; Trusted Computing Platforms

Abstract. Cloud computing represents one of the most significant shifts in information technology many of us are likely to see in our lifetimes. It offers an innovative business model for organizations to adopt IT services without upfront investment. Cloud computing moves the application software and databases to large data centers, where the management of the data and services may not be fully trustworthy. Security is one of the major issues which hamper the growth of cloud. The security for cloud computing is emerging area for study and this paper provide technical components of cloud computing and security idea in terms of cloud computing based on analysis of cloud security treats.

Introduction

According to the NIST definition, key characteristics of cloud computing include on-demand self service, broad network access, resource pooling, rapid elasticity, and metered service similar to a utility [1]. There are also three main service models—software as a service (SaaS), in which the cloud user controls only application configurations; platform as a service (PaaS), in which the cloud user also controls the hosting environments; and infrastructure as a service (IaaS), in which the cloud user controls everything except the datacenter infrastructure. Amazon EC2 is a well known example of IaaS, Google App engine is an example of PaaS and salesforce.com is an example of SaaS. Further, there are four main deployment models: public clouds, accessible to the general public or a large industry group; community clouds, serving several organizations; private clouds, limited to a single organization; and hybrid clouds, a mix of the others.

It extends Information Technology's (IT) existing capabilities. In the last few years, cloud computing has grown from being a promising business concept to one of the fast growing segments of the IT industry. But as more and more information on individuals and companies are placed in the cloud, concerns are beginning to grow about just how safe an environment it is. Security issues in cloud computing has played a major role in slowing down its acceptance, in fact security ranked first as the greatest challenge issue of cloud computing. After several years of focusing on cloud as a delivery model for their solutions, security vendor strategists are finally turning their attention to securing broader IT application and data workloads as these migrate from corporate data centers into managed cloud services. This shift, from security in the cloud to security of the cloud, marks the beginning of a significant and sustained transformation for the IT security market. This work is a survey more specific to the different security issues and the associated challenges that has emanated in the cloud computing system [2].Cloud security is a complex issue, involving the different levels of the cloud, external and internal threats, and responsibilities that are divided between the user, the provider and even a third party. This paper provides technical components of cloud computing and security idea in terms of cloud computing based on analysis of cloud security controls and threats. In the same time, it proposes a trusted cloud computing platform (TCCP) for ensuring the confidentiality and integrity of computations that are outsourced to IaaS services.

Components of Cloud Computing

As shown in the Fig. 1, key functions of a cloud management system is divided into four layers, respectively the Resources and Network Layer, Services Layer, Access Layer, and User Layer. Each layer includes a set of functions [3]:

1. The Resources and Network Layer manages the physical and virtual resources.
2. The Services Layer includes the main categories of cloud services, namely, NaaS, IaaS, PaaS, SaaS/CaaS, the service orchestration function and the cloud operational function.
3. The Access Layer includes API termination function, and Inter-Cloud peering and federation function.
4. The User Layer includes End-user function, Partner function and Administration function.

Other functions like Management, Security and Privacy, etc. are considered as cross-layer functions that covers all the layers. The main principle of this architecture is that all these layers are supposed to be optional. This means that a cloud provider who wants to use the reference architecture may select and implement only a subset of these layers. However, from the security perspective, the principal of separation requires each layer to take charge of certain responsibilities. In event the security controls of one layer are by passed (e.g. access layer), other security functions could compensate and thus should be implemented either in other layers or as cross-layer functions.

Cloud Security Controls and Threats

Security threats on cloud users are both external and internal. Many of the external threats are similar to the threats that large data centers have already faced. This security concern responsibility is divided among the cloud users, the cloud vendors and the third party vendor involved in ensuring secure sensitive software or configurations. Cloud security architecture is effective only if the correct defensive implementations are in place. Efficient cloud security architecture should recognize the issues that will arise with security management. The security management addresses these issues with security controls. These controls are put in place to safeguard any weaknesses in the system and reduce the effect of an attack. While there are many types of controls behind cloud security architecture, they can usually be found in one of the following categories [4]: **Deterrent controls**: These controls are set in place to prevent any purposeful attack on a cloud system. Much like a warning sign on a fence or a property, these controls do not reduce the actual vulnerability of a system. **Preventative controls**: These controls upgrade the strength of the system by managing the vulnerabilities. The preventative control will safeguard vulnerabilities of the system. If an attack were to occur, the preventative controls are in place to cover the attack and reduce the damage and violation to the system's security. **Corrective controls**: Corrective controls are used to reduce the effect of an attack. Unlike the preventative controls, the corrective controls take action as an attack is occurring. **Detective controls**: Detective controls are used to detect any attacks that may be occurring to the system. In the event of an attack, the detective control will signal the preventative or corrective controls to address the issue.

Threats for Cloud Computing Users are as follows[5]: first generation biosensor, loss of governance, loss of trust, service provider lock-in, unsecured cloud service user access, lack of information/asset management, data loss and leakage. Threats for cloud service providers are as follows[5]:responsibility ambiguity, protection inconsistency, evolutional risks, business discontinuity, supplier lock-in, license risks, bylaw conflict, bad integration, unsecured administration API, shared environment, hyper visor isolation failure, service unavailability, data unreliability, abuse right of cloud service provider.

Cloud Security and Privacy

Identity management: every enterprise will have its own identity management system to control access to information and computing resources. Cloud providers either integrate the customer’s

identity management system into their own infrastructure, using federation or SSO technology, or provide an identity management solution of their own. **Physical and personnel security**: Providers ensure that physical machines are adequately secure and that access to these machines as well as all relevant customer data is not only restricted but that access is documented. **Availability**: Cloud providers assure customers that they will have regular and predictable access to their data and applications. **Application security**: Cloud providers ensure that applications available as a service via the cloud are secure by implementing testing and acceptance procedures for outsourced or packaged application code. It also requires application security measures are in place in the production environment. **Privacy**: Finally, providers ensure that all critical data (credit card numbers, for example) are masked or encrypted (even better) and that only authorized users have access to data in its entirety. Moreover, digital identities and credentials must be protected as should any data that the provider collects or produces about customer activity in the cloud. **Legal issues**: In addition, providers and customers must consider legal issues, such as Contracts and E-Discovery, and the related laws, which may vary by country.

Trusted Computing Platforms

Traditional trusted computing platforms like Terra take a compelling approach to this problem [5]. For example, Terra is able to prevent the owner of a physical host from inspecting and interfering with a computation. Terra also provides a remote attestation capability that enables a remote party to determine upfront whether the host can securely run the computation. This mechanism reliably detects whether or not the host is running a platform implementation that the remote party trusts. These platforms can effectively secure a virtual machines (VM) running in a single host. However, many providers run data centers comprising several hundreds of machines, and a customer's VM can be dynamically scheduled to run on any one of them. This complexity and the opaqueness of the provider backend create vulnerabilities that traditional trusted platforms cannot address.

The Trusted Computing Group (TCG) [6] proposed a set of hardware and software technologies to enable the construction of trusted platforms. In particular, the TCG proposed a standard for the design of the trusted platform module (TPM) chip that is now bundled with commodity hardware. The TPM contains an endorsement private key (EK) that uniquely identifies the TPM (thus, the physical host), and some cryptographic functions that cannot be modified. The respective manufacturers sign the corresponding public key to guarantee the correctness of the chip and validity of the key.

In a computer and service systems, access is a specific type of interaction between a subject and an object that results in the flow of information from one to the other. Exactly what the subject does when it accesses the object is further defined by introducing access modes such as read, read-write, write, and execute. Access control deals with the limits on the interactions between subjects and objects [7].

Trusted Cloud Computing Platform

We present the trusted cloud computing platform (TCCP) that provides a closed box execution environment by extending the concept of trusted platform to an entire IaaS backend. The TCCP guarantees the confidentiality and the integrity of a user's VM, and allows a user to determine up front whether or not the IaaS enforces these properties. TCCP enhances today's IaaS backbends to enable closed box semantics without substantially changing the architecture as shown in Fig. 2. The components of the trusted cloud computing platform include a set of trusted nodes (N) and the trusted coordinator (TC). The untrusted cloud manager (CM) makes a set of services available to users. The TC is maintained by an external trusted entity (ETE). The trusted computing base of the TCCP includes two components: a trusted virtual machine monitor (TVMM), and a trusted coordinator (TC). The TCCP must guarantee that the node's configuration remains trusted; otherwise the node could compromise the security of the TCCP.

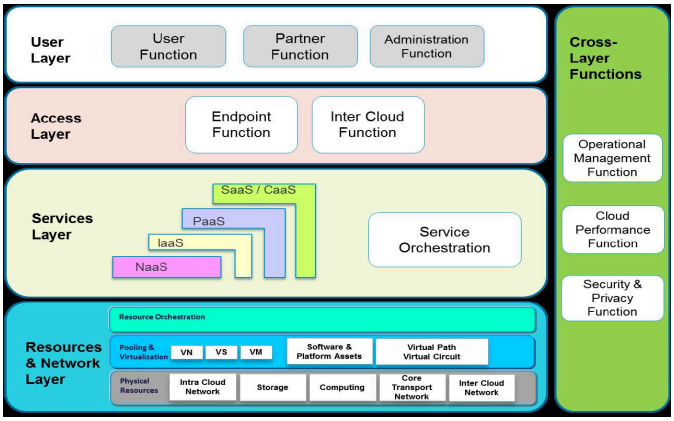

Fig. 1 Key functions of a cloud management system

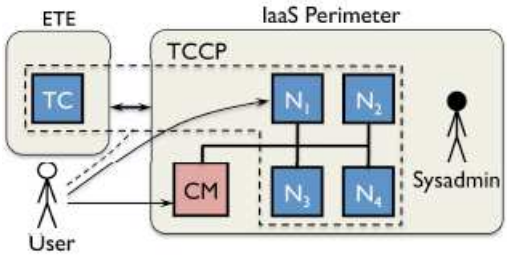

Fig. 2 Changing the architecture of TCCP

Conclusions

In this paper, we argue that concerns about technical components of cloud computing and security idea in terms of cloud computing based on analysis of cloud security controls and threats. In the same time, it proposes a trusted cloud computing platform (TCCP) for ensuring the confidentiality and integrity of computations that are outsourced to IaaS services. We plan to implement a fully functional prototype based on TCCP design and evaluate its performance in the near future.

Keywords：Internet of Things;RFID; Cloud Computing

Abstract. With the rapid development of information technology and network technology， especially the RFID technology, the development of internet of things has been greatly promoted. Meanwhile, the integration of the technology of internet of things and the Cloud Computing products the increasing number of information goods based on the RFID technology. This paper mainly expounds the application of the integration of the technology of internet of things and the Cloud Computing by analysing bar code which are extensively applied in the RFID technology, and interprets the application research of orientation tracing, remote control and information security products based on the RFID technology.

Internet of Things

Since the concept of Internet of Things was proposed in 1999, it has been gotten more and more attention, which was called the third wave of the world information industry after the computer, internet. Recently, with the constantly improvement and widely application of the core technologies, such as RFID, sensor technology, global standard of Internet of Things, the Internet of Things has been a hot topic that was gotten board attention at home and abroad.

The concept of "networking" was developed on the basis of the concept of "internet", it extends and expands its client to the between of any goods, which is the concept of network of conducting information exchange and communication, and it could also be named "internet of goods attached". Specifically speaking, Internet of things refers to as IOF, which is the network that through the sensing equipment information, such as radio frequency identification (RFID) device, infrared sensors, global positioning system, laser scanner, according to the agreement, it connects any goods and Internet, conducting exchange of information and communication, in order to realize intelligent identification, location, tracking and monitoring and management. Its purpose is to let all goods can remote perception and control, and combine with internet to a more wisdom production system of life.

The concept of "Internet of Things" evolves continuously, which named from "the wisdom of earth" of American to "the perception of China" of China, M2M is the specific pattern that the internet of things are using now. M2M represents the connection and communication of Machine to Machine, Man to Machine, Machine to Man, Mobile to Machine, which covers the technologies and methods that realized among all the people, Machine, systems' communication connection.

The blockage of the network development

With the internet of things gradually applied, its unprecedented function are slowly thorough popular feeling, everybody was very forward with a change of meaning that the arrival of the era of internet of things. But, as a new product, the road of internet of things will be difficult and long, currently ,we are facing the five big bottleneck .

A. the industry standard is lacking

This is the biggest constraining bottleneck. At present, the development of internet of things in all countries is different, countries all over the world have different standards, and mutual compatibility. Different industry related technology and product also have each difference, the uniform standard won't achieve real interworking.

B. Security problems

Security is the most pressing of the internet of things, which will greatly influence the development and application of this technology. The sensing technology content networking is mainly RFID,implant the chip, the products, could be perceived by anybody, it can be convenient to carry on the management by this system. But it also has a huge problem, other people are able to perceive, so how to do in perception, transmission, application process, these valuable information can be adopted by us, but not used by others. This needs the safety fluctuation and formed a strong security system. Now, what should be said that security problems, how to deal with these problems, how to screen is some very complex problems, even is not clear.

C. Unified agreement

The internet of things is the extension of the Internet thing, the former's core level based on TCP/IP protocol, it would also involve various types of agreement, GPRS/CDMA, text messaging, sensors, cable, etc channels, The internet of things need a uniform protocol stack.

D. Expansion and compatible with IP address problems

To ensure that each item in the content can be looking for to, networking must assigne a unique address to everyone. Because of the internet of things related to hundreds of thousands of items, so many things to the IP address of the network, it will lead to the current use of IPv4 resource exhaustion, it needs the support for IPv6. Transition form IPv4 to IPv6 is a long process, so the internet of things once use IPv6 address, which will inevitable result of the compatibility issue of existence and IPv4.

E. The ecological system (Eco-system)

Stability problem ,for the internet of things, it needs many fields, such as hardware with the coordination, firmware, software, (firmware) interface, etc. This is a big industry chain, only put a complete set up the ecological system, the internet of things can truly networking the sustainable development.

The strategies of the development of the Logistics Network

The development of the Logistics Network is still in the primary stage in the whole world, which will face variety problems. How to promote the development the Logistics Network ? How to solve the problem in the course of the development, due to the cooperation of the whole world. In my opinion, we can start with following invention at present.

A. Establish the standard system

The standard is the unified specification to any technology, the whole industry and the market will become confusion if there is no unified standard, the users can not choose and apply in more situations. The development of the Logistics Network is still in the primary stage in the world, there are no uniform standards, and the missing of the standard will restrict the development greatly. The basic problem which will be solved in the primary stage is to reinforce the international cooperation, draw up the related international standard.

B．Breakthrough the core technology of the sovereign intellectual property rights

The core technology of the sovereign intellectual property rights are the fundamental driving force of the sustainable development of the Logistics Network. As the emerging technologies of the national strategy, it will face more and more problems in the future development in the international competition, if we have no crucial core technology. Therefore, the most important in the development of the Logistics Network is to establish national and area research center, and then, grasp the core technology of the sovereign intellectual property rights.

C．Formulate the active and feasible policies

The Logistics Network is the strategic and emerging technology, which play more and more important role in the national strategy and sustainable development. According to the different characteristics of the application, the country consort to offer the dedicated or shared frequency resources. The country also provide related preferential policy in the industry of the Logistics Network, which similar to the software industry, IC industry. The administration, the production sector, the teaching institutions and the research institute should be responsible for the affairs which belongs to themselves, and committed to the cultivate demand, applied research and core technology research, carry out standard strategy and promote the industrial distribution, in order to promote the form and the development of the Logistics Network industry chain.

D．Actively coordination and cooperation among authorities in different area

The application area of the Logistics Network is very wide, there is so much overlapping in many industries, which belongs to different government function department. In order to guarantee the smooth development of the Logistics Network effectively, we should strengthen the coordination and cooperation in the course of the industry. For example: strengthen the cooperation of the radio and TV, telecommunications and the traffic, in order to establish the information and intelligent traffic system.

E．Take precedence the major special industry in the implement application area

We also have to establish some major application special to promote the development of the Logistics Network industry, promote the key technology research and application demonstration, according to the industry development mode that experimental partly and focus on demonstration, to promote the sustained orderly development in the whole industry.

The prospect of the Logistics Network is very optimistic, the value of the Logistics Network was forecasted to as 30 times as the internet. Though, the development of the Logistics Network will face many resistances, which need verities support from the government, the enterprise, the association of the industry , the media ,even the public, only in this way we can realize a new and transformational period.

Research on the security of the digital learning resources library based on cloud storage

Hui Cao

Henan Radio and Television University, Zhengzhou 450008, China

402793927@qq.com

Keywords: cloud storage, digital learning resources library, cloud system, hidden danger, safe storage.

Abstract. This paper mainly analysis the hidden dangers exist in the process of the construction and application of cloud system, and presents new strategies of safe storage for the digital learning resources library based on cloud storage to realize the protection of data transition and storage.

Introduction

The digital learning resources library based on cloud storage is a cloud system, that is used to solve the Integration, integration and sharing of the lifelong learning resources which is distributed, heterogeneous, massive and multi mode; and that offers the public services of digital learning resources. The digital learning resources library based on cloud storage is the specific application of storage management of the digital learning resources, through the cluster applications, grid technology and distributed file system and other functions, this system adapts the application software to organize the devices, that are distributed in different regions of the network and in a large variety of different types, to load balancing and work together to offer data storage and business visits for the users of the digital learning resources library.

With the increase in the number of users of cloud storage, the data storied in cloud increase, whether these data are security has become a hot issue. These years, data leakage incidents occurred frequently, for example, in 2009, 30000 customers' credit cards information of Japanese life-insurance company Aliko leaked[1]; in 2011, 6000000 users' information of the largest programmer community in China were stolen[2]; in 2013, the secrete file about American National Security Agency (NSA) stole data was exposed[3]. These events indicate that the data is lack of strict protection and the systems still exist security flaws in the network world.

Whether the cloud storage services how powerful, the cloud storage can solve the security problem is always the determining element of the cloud storage life. Only the safe cloud storage can stimulate the user enthusiasm. Therefore, cloud storage security must get people's attention. This paper mainly analysis the hidden dangers exist in the process of the construction and application of cloud system, and presents new strategies of safe storage for the digital learning resources library based on cloud storage to realize the protection of data transition and storage.

The hidden danger of the digital learning resources library based on cloud storage

User access control: User access control is mainly refers to the identity authentication. Rapid and effective user authentication determines the safety and efficiency of cloud service. The system should realize single sign on, Strengthen the identity authentication system, take a unified way to authenticate users of different levels, the users can have a unique identity authentication to access system data to ensure legal users accessing safe and reliable data at any time.

Data transmission security: The system data story in the cloud, data management and maintenance is carried out through the network. The Internet environment is very complex, the system data face the hacker's attack at any time and have the risk of interception. If the data is not encrypted or the encrypted data are easy to crack, the accident of Leakage of

information, data destruction and service interruption will happen. To protect the data cloud storage system security must enhance the password technology and platform reinforcement technology so that ensure the integrity of the system and identity authentication based on PKI, as well as the security server.

Storage virtualization: The most popular understanding of the storage virtualization technology is the abstract expression on storage hardware resources. They provide comprehensive and useful function service uniformity through integrating one (or more) target service or function with other additional functions. Typical virtualization includes the following situations: shield the complexity of system, increase or integrate new functions, simulate, integrate or disintegrate available service etc. Virtualization is in one or more entities and these entities are used to provide storage resources or other services. Users do not have to care about their data through which path to which a specific storage device.[4] Storage virtualization contribute to improve the storage efficiency and reduce the storage cost, at the same time, bring some security risks. Since the physical location of data storage can not be clearly defined, the difficulty of protection measures about data storage increases. The system have to adapt effective strategies of spatial separation and effective division of physical storage space to ensure the security of user data and data switching and transmission security between the virtual platforms.

Data audit: Data audit can record real time data activities on the network, manage data operation with fine grained auditing, give an alarm of the risk data suffer from and block attacks. Through recoding, analyzing and reporting behaviors that users visit database, it helps users to produce compliance report, trace accident, enhance recording network behavior of Internal and external database, improve data assets security.[5]

Cloud service provider: The digital learning resources library based on cloud storage to be deployed on a commercial cloud, must choose a cloud service provider. How to ensure data security of infrastructure, the key application and sensitive data, it is important to choose the cloud service provider. Cloud service providers must have the technical strength to ensure the security of data, and provide third party audit to prove that they have this ability.

Countermeasures of safe hidden danger of the digital learning resources library based on cloud storage

Strengthen the management and monitoring: The digital learning resources library based on cloud storage must strengthen the monitoring capacity of user access behavior, take authority verification and control measures to monitor and limit users' behavior and permissions. Measures to protect the resource base for the core data can be from two aspects, one is to adopt the perfect encryption algorithm to encrypt core data, on the other hand is that the core data is arranged in the private cloud and the non sensitive data is arranged in a public cloud. The resource base needs to detect and protect base threat from the client, adopts monitoring technology to guard against unknown threats. When the suspicious flow appears, cloud monitoring center will analyze data by the powerful computation ability and send the analysis results to all the clients and security gateway to improve the control ability of the resource base for security threats.

Enhance the robustness of the system: The system adopts advanced password technology to realize security encryption of data. During the transfer, the data can not be decrypted even if stolen. Through the reinforcement on the server, operating system, database and application system, timely patch the application and system, reduce the number of vulnerabilities, ensure the security of the server and programs and prevent illegal tampering.

Safety measures based on virtual technology: System memory safety includes the authentication service, data encryption storage, safety management, safety log and audit. According to the identity of the user, the system grants different levels of permissions. The user can only operate on the authorization data so as to protect users' private data and space. When the resource library and other application sharing server, the system should ensure users of different applications have separated operating system and application software, isolate storage data fully in logic and realize resource database communication security during virtual machine system, software and platform to ensure the security of data switching, data transmission, data synchronization between multiple virtual platforms.[6]

Data backup strategy: The system adopts cloud backup service to storage data remotely. The data will be stored on the local and cloud after data backup. The clouds can be one or more private data center or a virtual data center. Local backup save recent data and the clouds storage all data. Local backup can be used to quickly restore data to the nearest backup node. Backup data in cloud is used to recovery data to prior backup node, that can be used for disaster recovery scenarios or restore data to a different site.

Conclusion

With the construction and application continually deepening and expanding, the safety issues of operation, maintenance and customer service of resource database will be more prominent. The system should be analyzed comprehensively for system security threats in design phase and use advanced security technology, not only that, but also follow the latest development in security field continually to make sure the system can respond to network environment varied from minute to minute.

Key words: Data mining; AHP; Elo rating system

Abstract. The ranking of coaches is of great significance for sports teams to find talented coaches. Traditional ranking mechanism is relatively subjective which is usually accomplished by voting. In this paper, we establish a ranking mechanism based on both subjective and objective factors. We use data mining method to classify and analyze the data. The regression tree and the decision tree (CART) are used to narrow down the number of coaches to a reasonable scale. We put forward our AHP model to rank the "candidates" and propose a coach rating analysis system (CRAS) for evaluating the accuracy of system. We verify our ranking system more comprehensive in terms of the evaluation of the coaches through analyzing the result. The proposed mechanism is also significant to find potential coaches.

Introduction

The ranking of coaches is of great significance for sports teams to find talented coaches. The traditional ranking mechanism is relatively subjective and it is usually accomplished by voting, therefore sometimes the result is not that convincing. According to the final goal of coaches ranking, we collect the related data on the internet [1, 2] and use them to improve the objectivity. To find out the top 5 coaches we firstly use data mining [3] (the analysis step of the "Knowledge Discovery and Data Mining" process, or KDD) methods to classify and analyze the data. Then we introduce CART [4] to narrow down the number of the candidates according to the features we have. After the filtering we change the evaluation features to accomplish further ranking. The reasonability of every chosen feature is verified by the correlation coefficient analysis [3] on SPSS. After the analysis we found the relative features for the AHP model [5] we build to find out the result that suits our goal of coaches ranking best [6]. Then we introduce Elo rating system [7], which is a method for calculating the relative skill levels of players, and propose our CRAS model to achieve our ranking goal. Finally we analyze the result and find out our ranking mechanism as time-irrelevant with flexibility and objectivity. It can be applied into other fields such as qualitative comparison or other related fields.

Problem formulation

Suppose our goal is to find out the top 5 college coaches in the last century and we take the sport of American football as an example. Then we should collect the data we need and analyze it. We have thousands of candidates, therefore it is reasonable to narrow down the range to a reasonable scale [8].

In this section data filtering model is mainly designed according to the ideology of CART. We use this model to process data, which can be divided into two major phases[9]:

Phase1: Primary filtering. According to the ideology of recursively dividing the independent features' space. We use the median of *OG*, *NC* and the mean value of *OP*, *SRS* one by one to narrow down the range of the candidates to a reasonable scale of 3%-5%.

Phase2: Limited filtering. According to the ideology of cutting the data with the validation features, we choose the top 5 candidates according to *OG*, *OP*, *NC* and *SRS* respectively and then collect them together. It is reasonable that if there is no feature ranking top 5(Suppose our goal is to acquire the top 5 coaches), then the candidate have no reason to stay in the candidate list.

We want to analyze a coach from 5 main aspects: professionalism; ability; achievement; psychological control on major matches; support rate. Each of the candidate has 6 main features:

1. *OG*: game number that the coach directing in NCAA data record -Stands for professionalism.
2. *OP*: win-lost percentage in NCAA data record -Stands for ability.
3. *NC*: NCAA championship winning time -Stands for achievement.
4. *FP/FFP*: winning percentage of NCAA final/final four -Stands for psychological control on major matches.
5. *Ye*: year of the coaches' career in college -Stands for professionalism.
6. *SRS*: a rating system proposed by the NCAA official -Stands for Support rate.

In primary filtering model, we choose *OG*, *OP*, *YE* and *NC* as our main features considering their integrity, comprehensive and generic. After the primary filtering, we need to change the evaluation features. In order to determine the main features during the evaluation of the coach, we have done correlation analysis for all the features. The result is listed in Table.1.

Table. 1 Correlation Coefficient (CC)

Spearman		*YE*	*OG*	*OP*	*NC*	*SRS*
YE	CC	1.000	0.979	0.036	0.438	0.165
	Sig	0.000	0.000	0.775	0.000	0.186
OG	CC	0.979	1.000	0.031	0.547	0.156
	Sig	0.000	0.000	0.804	0.000	0.210
OP	CC	0.036	0.031	1.000	0.130	0.561
	Sig	0.775	0.804	0.000	0.298	0.000
NC	CC	0.438	0.547	0.130	1.000	0.216
	Sig	0.000	0.000	0.298	0.000	0.082
SRS	CC	0.165	0.156	0.561	0.216	1.000
	Sig	0.186	0.210	0.000	0.082	0.000

If correlation coefficient ranks high and sig ranks low, the corresponding parameters are more likely to be correlated. Table.1 shows that *YE* and *OG* are significantly correlated, while others are not. Therefore, we choose one of the features between *YE* and *OG* to represent the professionalism. *NC* can reflect coaches' achievement of high level. *SRS* reflects the support rate of coaches. Finally, we decided to adopt the following features in the limited filtering model: *OG*, *OP*, *NC* and *SRS*. After the limited filtering, the data are reduced to less than 15. We can see *FP/FFP* is a generic factor for these coaches. Then, *OG*, *OP*, *NC*, *FP/FFP* and *SRS* are selected for the AHP model.

AHP model

Our AHP model aims at generating the top 5 according to the parameters: *OG*, *OP*, *NC*, *FP/FFP* and *SRS*. The Structure of the AHP model consists of 3 different layers: goal; criteria; alternatives. The relationship is shown in fig.1.

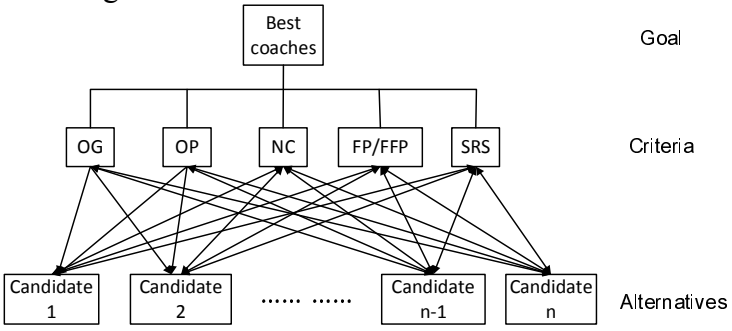

Fig. 1 AHP model hierarchy

The criteria was achieved by the analysis of the data and the target. The alternatives refer to the candidate list and it is achieved by the data filtering. The relative strength of rating scale 'a_{ij}' is achieved by the analysis against the value of the 5 features listed on the criteria. A rating scale is shown on table.2, where C_i refers to the absolute strength. Through the AHP model we got the preliminary relative strength 'R_{ij}'.

Table. 2 Rating scale

scale a_{ij}	meaning
1	$C_i = C_j$
3	$C_i > C_j$ and R_{ij} is tiny
5	$C_i > C_j$ and R_{ij} is small
7	$C_i > C_j$ and R_{ij} is moderate
9	$C_i > C_j$ and R_{ij} is
2,4,6,8	$C_i > C_j$ and R_{ij} is between the adjacent R that mentioned above
1,1/2,...,1/9	$C_i < C_j$ and R_{ij} is the reciprocal of the R that mentioned above

The 5 features may be impacted by time. For example the number of matches taking place 100 years ago is definitely less than that of today. Inspiration: considering that it is impossible to take everything into consideration and the data we got have its limitation. We introduce the Elo rating system to combat it. If we want to compare two different coaches A and D, whose careers were located in the different timespans. We may have to introduce B and C who have competence records enough to build a relation diagram. It is shown in Fig.2.

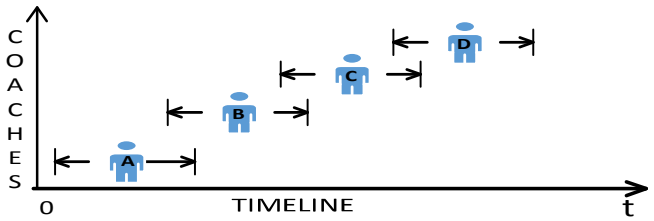

Fig.2 Relation schema

Assume coach i and j represent two coaches. $i = j$ means two same coaches. $i \neq j$ means two different coaches. E_i and E_j represent the expected score for coach i and coach j. There is 3 different results of a match: win; lose; tie. Each ot them have its percentage. Assuming that each coach's base score is 100, we change the base value according to the AP poll to get the initial rating R_i of coach i. Then we use equations to get the final R_i. With the introduction of K-factor we, we not only consider the competition information but also consider the potentiality of a coach. We compare the AP post of two different coaches and limit the range of it from1 to 25. Table.3. show the divide 5 levels we divided for the strength of coaches.

Table. 3 Strength of coaches

Difference of AP post	Sacle coach ij	Meaning
[-25,-20)	1	Preceding large stronger
[-20,-15)	3	Preceding moderate stronger
[-15,-10)	5	Preceding small stronger
[-10,-5)	7	Preceding tiny stronger
[-5,0)	9	Equal
(0,5]	-1	Equal
(5,10]	-3	Behind tiny stronger
(10,15]	-5	Behind small stronger
(15,20]	-7	Behind moderate stronger
(20,25]	-9	Behind large stronger

The expected score E_i of coach i follows the formula:

$$E_i = 1/(1+10^{(R_j - R_i)/40}), \quad (1)$$

Where R_j is the coaches' rating of coach j. The CRAS model is a linear enhancement proportional to the amount by which a coach over-performed or underperformed his expected score. The maximum

possible per game called the *K*-factor, was set to $K = 16$ for the stronger coaches and $K = 32$ for the weaker coaches. *K*-factor may reflect the potentility of a coach. Supposing coach *i* was expected to score E_i points but actually scored S_i points. The formula for updating his rating is:

$$R_i^{'} = R_i + K(S_i - E_i) \quad (2)$$

Table.4 listed part of the results compared with the result on the NCAA official website[10].

Table. 4 Results

scale a_{ij}	AHP model	Weight(AHP)	CRAS model	Final Ri	NCAA list
1	Joe Paterno	0.1568	Bear Bryant	92.45	Bear Bryant
2	Tom Osborne	0.1511	Woody Hayes	86.42	Nick Saban
3	Bobby Bowden	0.1455	Bud Wilkinson	73.6	Bobby Bowden
4	Bear Bryant	0.1236	Joe Paterno	67.16	Eddie Robinson
5	Barry Swither	0.1116	Bobby Bowden	62.86	Woody Hayes

Conclusions

According to the NCAA list, the CRAS model performs better than the AHP model. Supported by the data, we consider our system more reliable and objective than the traditional methods. The proposed system is not limited by the time line horizon, the gender and the different sports field. With the development of computer technology and data technologies, our ranking system will be greatly expanded and applied into other fields such as qualitative comparison or other related fields. For sports team, the proposed system has a huge advantage to find the talent coaches.

Keywords: Ontology, Aircraft Carrier, Geographic Information

Abstract. This paper aimed to build an ontology of aircraft carrier geographic information, defined ontology's constants, predicates, functions about aircraft carrier geographic information, and proposed a series of competency questions which could be solved by this ontology. Paper presented disjoint axioms, simple axioms and complex axioms of this ontology around these competency questions, and proved the consistency of the carrier ontology by examples. Finally, paper gave the answers for competency questions.

Introduction

An ontology is a declaration of terminology together with a specification of the meaning (semantics) of the terms, just likes a particular conceptual model. Ontology of aircraft carrier can help us understand the information of carrier easily and infer the actions of the carrier during the next period of time. Geographic information is an important part of aircraft carrier ontology, regardless of the carrier itself, or people related to carrier, things, facilities, events ..... they are closely associated with geographic information. Geographic information including aircraft carrier, people, ports and other's locations and coordinate information, you can get this information to analyze the aircraft carrier state, route, and even the tasks being performed. Such as through the port to get the docked state of aircraft carrier; Based on the location of boatyard that build aircraft carrier to get the country which this aircraft carrier belong to; Based on the sail track of aircraft carrier at sea to get its route and then analyze the task being performed ..... So reasoning geographic information of carrier by ontology can provide more information, and that is necessary for reasoning of the country's military action in sea.

Related Work

Recently, ontology was emerging as a new hotspot of research in computer science [1]. Contents of those researches involved all aspects of ontology, including the theory concept; application of information system; semantic Web etc [2]. Many domestic scholars have done research about geographic information ontology. Li Hongwei [3] elucidated the exact meaning of geographic ontology and the function and the sense of ontology in the geographic information science domain, presented a three-layer ontology framework by acting the basic concept design for geographic ontology, and showed the ontology's research potential and value in geographic information science domain. Huang Yong-qi [4] discussed how to adopt three theories to build geo-ontology, and prove its solution was feasible by experiment. Liu Wei and Gu He-he [5] proposed a solution for spatial data retrieval, took Dalian Bay land utilization ontology as the example, and showed the availability of its method by experiment. Foreign scholars have done many studies on ontology of geographic information. Agustina Buccella [6] proposed a novel system to integrate geographic sources by formalizing the information as normalized ontologies and provided a consistent and complete integration of their sources by testing in the context of projects of the Italian Institute for Environmental Protection and Research.

Although there were many researches of geographic information ontology, few scholars did research on building the ontology of aircraft carrier geographic information. There was no related literature in the result by searching in all the literatures with “aircraft carrier ontology” as keyword. This paper aimed to build an ontology of aircraft carrier geographic information, provided a detailed description of all the objects of aircraft carrier geographic information. It was important for the construction of ontology of aircraft carrier.

Competency Questions

Before building this ontology, we should find out what the ontology’s goals are，in other words, we should make it clear that what the requirements of using ontology to complete task are. Competency questions are these requirements which can be specified a set of queries that the ontology should be able to answer. We propose the following competency questions for the ontology of aircraft carrier geographic information. Note that x and t represent unknown quantities.

- Which country doses the aircraft carrier x belong to?
- Which port does the aircraft carrier x stay at?
- Which ocean is the aircraft carrier x shipping in?
- What is the longitude of the aircraft carrier x?
- Which aircraft carrier is at the position x?
- What are the positions of the route points when carrier x carry out task t?
- What is the northernmost latitude of area x?

Intuition

Aircraft carrier geographic information mainly concerns the area related to carrier. Figure 1 shows the basic elements of our ontology which is build by intuition.

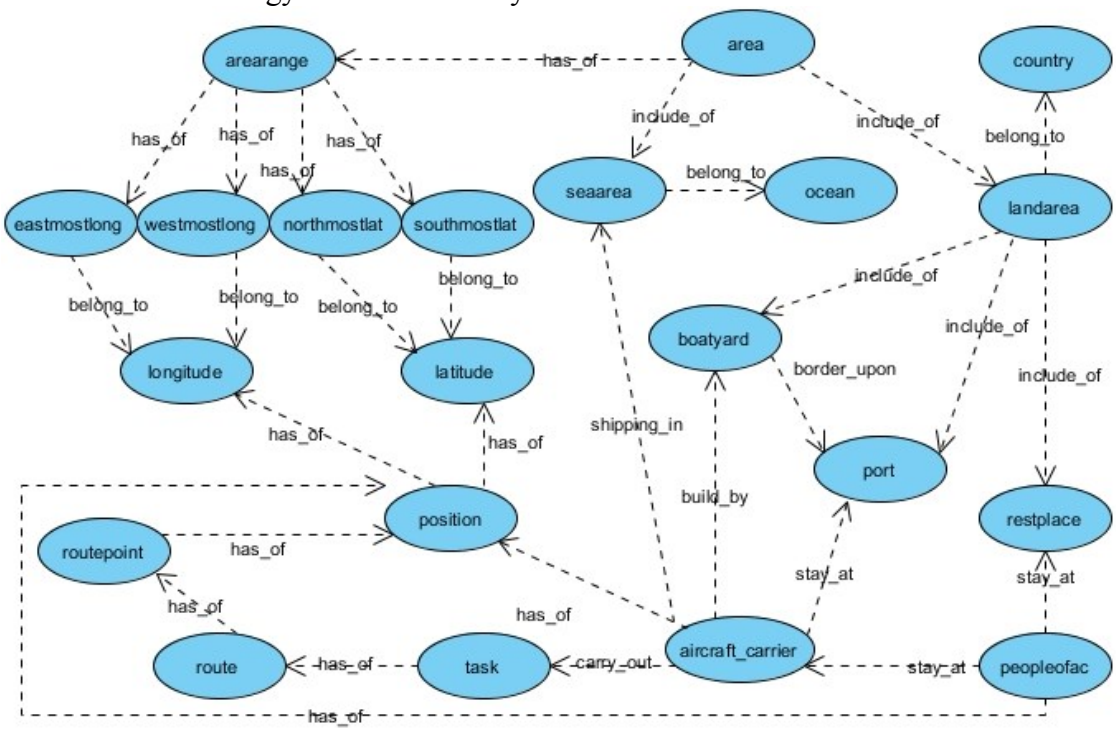

Figure 1: Structure of the aircraft carrier geographic information ontology

Through the understanding of the aircraft carrier, we can get following intuition.

Intuition 1: Areas related to aircraft carrier include the sea and land. The sea area belongs to one ocean and the land area belongs to one country. The land areas are mainly ports, boatyards and rest place where the people related to carrier live in.

Intuition 2: Each area has its range. The range of area has four attributes: easternmost longitude, westernmost longitude, northernmost latitude, southernmost latitude. The area range can be expressed by these four attributes.

Intuition 3: Aircraft carrier is built by boatyard and it sails in sea or stays at port. Aircraft carrier performs task, each task has its route. Aircraft carrier must pass through the route points given by the performing task.

Intuition 4: Route points and aircraft carriers, people have these positions. And each position has the exclusive longitude and latitude.

Nonlogical Lexicon

After giving the structure of ontology, we should get the nonlogical lexicon about aircraft carrier geographic information. The lexicon likes vocabulary that is one part of expressing knowledge. The lexicon contains the set of named individuals, types of objects, the set of attributes, relationships etc. Those lexicons are expressed by predicates, functions and constants. The following is our design of the nonlogical lexicon in our ontology.

Unary predicate

- aircraft_carrier(x) denotes object x is aircraft carrier.
- area(x) denotes x is a region.
- seaarea(x) is subclass of area(x) and denotes x is sea area.
- landarea(x) is subclass of area(x) and denotes x is land area.
- ocean(x) denotes x is an ocean.
- country(x) denotes x is a country.
- arearange(x) denotes x is the range of area.
- eastmostlong(x) denotes x is the easternmost longitude of an area.
- westmostlong(x) denotes x is the westernmost longitude of an area.
- northmostlat(x) denotes x is the northernmost latitude of an area.
- southmostlat(x) denotes x is the northernmost latitude of an area.
- boatyard(x) is subclass of landarea(x) and denotes x is a boatyard.
- port(x) is subclass of landarea(x) and denotes x is a port.
- restplace(x) is subclass of landarea(x) and denotes x is a rest place.
- position(x) denotes x is a position of an object.
- longitude(x) denotes x is longitude. West longitude is represented by negative
- latitude(x) denotes x is latitude. South latitude is represented by negative
- peopleofac(x) denotes x is people about aircraft carrier.
- task(x) denotes x is a task.
- route(x) denotes x is a route.
- routepoint(x) denotes x is a route point.

Binary predicate

- has_of(x,y) denotes the relation in which x has the property y.
- include_of(x,y) denotes the relation in which x include y.
- belong_to(x,y) denotes the relation in which x belongs to y.
- stay_at(x,y) denotes the relation in which x stay at y.
- build_by(x,y) denotes that aircraft carrier x is built by y.
- border_upon(x,y) denotes the relation in which x border upon y.
- carry_out(x,y) denotes that aircraft carrier x carry out task y.
- shipping_in(x,y) denotes that aircraft carrier x is shipping in sea area y.

Functions

- getlongitude(x). This function can get the longitude of position x.
- getlatitude(x). This function can get the latitude of position x.

Constants

There are many constants, and they will be presented in the practical application.

Axiom

According to the ontology, the axioms are based on the intuitions above. The building of axioms is in order to answer and solve the competency questions, and through axioms our ontology can express the competency questions necessary and sufficient. We just show the following examples of all kinds of axioms in our ontology.

Disjoint Axioms

- Sea area and land area are disjoint sets; Boatyard, port and rest place are disjoint sets.
  $(\forall x)seaarea(x) \supset \neg landarea(x)$ $(\forall x)boatyard(x) \supset \neg(port(x) \vee restplace(x))$
- At same area range, easternmost longitude and westernmost longitude are disjoint sets. Northernmost latitude and southernmost latitude are the same.
  $(\forall x)eastmostlong(x) \wedge has_of(y,x) \wedge arearange(y) \supset \neg westmostlong(x)$
  $(\forall x)northmostlat(x) \wedge has_of(y,x) \wedge arearange(y) \supset \neg southmostlat(x)$
- Longitude and latitude are disjoint sets.
  $(\forall x)longitude(x) \supset \neg latitude(x)$

General Axioms

1) Has_of:

- Axiom 1.1: One area must have one and only one area range.
  $(\forall x)area(x) \supset ((\exists y)arearange(y) \wedge has_of(x,y)) \wedge (\forall z)arearange(z) \wedge has_of(x,z) \wedge (y = z)$
- Axiom 1.2: One area range must have one and only one easternmost longitude. The same to westernmost longitude, northernmost latitude, southernmost latitude. We don't repeat them here.
  $(\forall x)arearange(x) \supset ((\exists y)eastmostlong(y) \wedge has_of(x,y)) \wedge (\forall z)eastmostlong(z) \wedge has_of(x,z) \wedge (y = z)$
- Axiom 1.3: One position must have one and only one longitude. The same to latitude.
  $(\forall x)position(x) \supset ((\exists y)longitude(y) \wedge has_of(x,y)) \wedge (\forall z)longitude(z) \wedge has_of(x,z) \wedge (y = z)$
- Axiom 1.4: Aircraft carrier must have one and only one position. The same to carrier-related people.
  $(\forall x)aircraft_carrier(x) \supset ((\exists y)position(y) \wedge has_of(x,y)) \wedge (\forall z)position(z) \wedge has_of(x,z) \wedge (y = z)$
- Axiom 1.5: Route point has one position, and there is only one position correspondence with this route point.
  $(\forall x)routepo\,\mathrm{int}(x) \supset ((\exists y)position(y) \wedge has_of(x,y)) \wedge (\forall z)position(z) \wedge has_of(x,z) \wedge (y = z)$
- Axiom 1.6: Agreed in our ontology, one task must have one route.
  $(\forall x)task(x) \supset ((\exists y)route(y) \wedge has_of(x,y)) \wedge (\forall z)route(z) \wedge has_of(x,z) \wedge (y = z)$
- Axiom 1.7: Route has some route points.
  $(\forall x)route(x) \supset (\exists y)has_of(x,y) \wedge routepo\,\mathrm{int}(y)$

2) Include_of:

- Axiom 2.1: The area includes sea area and land area.
  $(\forall x)area(x) \supset seaarea(x) \vee landarea(x)$
- Axiom 2.2: Boatyards belong to land area. Ports and rest place also belong to the land area. We also don't repeat them.
  $(\forall x)boatyard(x) \supset landarea(x)$

3) Belong_to:

- Axiom 3.1: Each one sea area belongs to only one ocean.
  $(\forall x)seaarea(x) \supset ((\exists y)ocean(y) \wedge belong_to(x,y)) \wedge (\forall z)ocean(z) \wedge belong_to(x,z) \wedge (y = z)$
- Axiom 3.2: Each one land area belongs to only one country.
  $(\forall x)landarea(x) \supset ((\exists y)country(y) \wedge belong_to(x,y)) \wedge (\forall z)country(z) \wedge belong_to(x,z) \wedge (y = z)$
- Axiom3.3: Easternmost longitude belongs to longitude. The same to westernmost longitude.
  $(\forall x)eastmostlong(x) \supset longitude(x)$

- Axiom 3.4: Northernmost latitude belongs to latitude. The same to southernmost latitude.
  $(\forall x)northmostlong(x) \supset latitude(x)$

4) Stay_at:

- Axiom 4.1: Either aircraft carrier ships in sea area or stays at port.
  $(\forall x)aircraft_carrier(x) \supset (\exists y)port(y) \wedge stay_at(x,y) \vee (\exists z)seaarea(z) \wedge shipping_in(x,z)$

5) Build_by:

- Axiom 5.1: Aircraft carrier was built by boatyard.
  $(\forall x,y)build_by(x,y) \supset aircraft_carrier(x) \wedge boatyard(y)$
- Axiom 5.2: Agreed in our ontology, there is only one boatyard built this aircraft carrier.
  $(\forall x)aircraft_carrier(x) \supset ((\exists y)boatyard(y) \wedge build_by(x,y)) \wedge (\forall z)boatyard(z) \wedge build_by(x,z) \wedge (y=z)$

6) Border_upon:

- Axiom 6.1: The two units are border upon to each other is port and boatyard.
  $(\forall x,y)border_upon(x,y) \supset (boatyard(x) \wedge port(y)) \vee (boatyard(y) \wedge port(x))$
- Axiom 6.2: A port border upon the boatyard so that the boatyard border upon the port.
  $\text{border_upon}(x,y) \supset \text{border_upon}(y,x)$
- Axiom 6.3: Each boatyard has only one port border upon.
  $(\forall x)boatyard(x) \supset ((\exists y)port(y) \wedge border_upon(x,y)) \wedge (\forall z)port(z) \wedge border_upon(x,z) \wedge (y=z)$

7) Carry_out:

- Axiom 7: Aircraft carrier carries out its task.
  $(\forall x,y)carry_out(x,y) \supset aircraft_carrier(x) \wedge task(y)$

8) Shipping_in:

- Axiom 8.1: Aircraft carrier ships in sea area.
  $(\forall x,y)shipping_in(x,y) \supset aircraft_carrier(x) \wedge seaarea(y)$
- Axiom 8.2: Every aircraft carrier only ships in one sea area.
  $(\forall x)(\exists y)aircraft_carrier(x) \wedge seaarea(y) \wedge shipping_in(x,y) \supset$
  $(\forall z)seaarea(z) \wedge shipping_in(x,z) \wedge (y=z)$

Complex axioms

- Axiom 9: Different aircraft carriers have different position.
  $(\forall x,y)aircraft_carrier(x) \wedge aircraft_carrier(y) \wedge (x \neq y) \supset$
  $(\exists xp,yp)position(xp) \wedge position(yp) \wedge has_of(x,xp) \wedge has_of(y,yp) \wedge (xp \neq yp)$
- Axiom 10: Aircraft carrier is shipping at sea area. The position of aircraft carrier is in the sea area range. That is to say its longitude will not exceed the scope of the longitude range of sea area. Its latitude will not exceed the scope of the latitude range of sea area too, we also don't give it. By the same token, when carrier is staying at port, its position is in the port.
  $(\forall x)aircraft_carrier(x) \wedge seaarea(y) \wedge shipping_in(x,y) \wedge position(xp) \wedge has_of(x,xp)$
  $\wedge arearange(yr) \wedge has_of(y,yr) \wedge eastmostlong(ye) \wedge has_of(yr,ye)$
  $\wedge westmostlong(yw) \wedge has_of(yr,yw) \supset (yw < getlongitude(xp) < ye)$
- Axiom 11: Aircraft carrier performing task and its position is same as the position of route point of the task.
  $(\forall x)aircraft_carrier(x) \wedge carry_out(x,k) \wedge task(k) \wedge has_of(k,r) \wedge route(r)$
  $\wedge has_of(r,pt) \wedge routepo\text{int}(pt) \wedge has_of(pt,p) \wedge position(p) \supset has_of(x,p)$

Consistency Proofs

After the building of ontology, we should test and verify its consistency. The following example can prove the above axioms are consistent.

Example

"Kitty Hawk" aircraft carrier (USS Kitty Hawk CV-63) is the U.S. Navy Kitty Hawk-class aircraft carrier of the first ship, "Kitty Hawk" aircraft carrier built by the boatyard in New York, watered in New York sea area in 1960, first entered service in 1961. New York sea area is in Atlantic.

After shakedown from Atlantic waters, the USS Kitty Hawk left Norfolk in August 11, 1961.Then USS Kitty Hawk carried out a task that joint exercise with the Brazilian Navy. The requirement of the task was that USS Kitty Hawk should pass Cape Horn in the October 1, pulled into Chile 's Valparaiso Harbor in October 13.

Then USS Kitty Hawk entered the Peruvian waters (easternmost longitude -76.87' , westernmost longitude -77.35', northernmost latitude -11.60', southernmost latitude -12.40') two days later. According to satellite monitoring the position of USS Kitty Hawk was (-77.50',-12.22') at that time.

Proof

1) By analyzing the first paragraph, we can get a series of constants:

aircraft_carrier(KittyHawk) seaarea(NewYorkSeaArea)
country(USA) boatyard(NewYorkBoatyard)
landarea(NewYork) port(NewYorkHarbor)
ocean(Atlantic)

These constants have some relationship between each other, expressed by the following formulas.

include_of(NewYork, NewYorkBoatyard) belong_to(NewYork, USA)
build_by(KittyHawk, NewYorkBoatyard) belong_to(NewYorkSeaArea, Atlantic)
border(NewYorkBoatyard, NewYorkHarbor)

Through axiom 2.2, axiom 5.1, axiom 5.2, axiom 3.1, axiom 3.2, we can get the facts:

belong_to(NewYorkBoatyard,USA) belong_to(NewYorkHarbor,USA)

Through axiom 6.1, axiom 6.2, axiom 6.3, we can get the fact:

border(NewYorkHarbor, NewYorkBoatyard)

2) By analyzing the second paragraph, we can get a series of constants:

country(Chile) routepoint(CapeHorn)
port(ValparaisoHarbor) position(CapeHornPosition)
task(JointExercise) latitude(-55.59')
route(JERoute) longitude(-67.16')
belong_to(ValparaisoHarbor, Chile)

The relationship between them is following:

carry_out(KittyHawk ,JointExercise) has_of(JERoute, CapeHorn)
has_of(JointExercise, JERoute) has_of(CapeHorn, CapeHornPosition)
has_of(CapeHornPosition, -55.59') $\wedge$ latitude(-55.59')
has_of(CapeHornPosition, -67.16') $\wedge$ longitude(-67.16')
getlongitude(CapeHornPosition)= -67.16' getlatitude(CapeHornPosition)= -55.59'

Through axiom 1.3, axiom 1.5, axiom 1.6, axiom 1.7, axiom 7, axiom 12, we can get the fact: has_of(KittyHawk ,CapeHornPosition) when Kitty Hawk carried out the JointExercise task in October 1.

Through axiom 8.1, axiom 4.1, we can get the fact:

stay_at(KittyHawk, ValparaisoHarbor) $\vee$ shipping_in(KittyHawk, ?seaarea) $\wedge$ belong_to(?seaarea, Atlantic), "?" express unknown.

3) By analyzing the third paragraph, we can get a series of constants and the relationship:

seaarea(PeruvianWaters) arearange(PeruvianWatersRange)
has_of(PeruvianWaters, PeruvianWatersRange)
has_of(PeruvianWatersRange, -76.87') $\wedge$ eastmostlong (-76.87')
has_of(PeruvianWatersRange, -77.35') $\wedge$ westmostlong (-77.35')
has_of(PeruvianWatersRange, -11.60') $\wedge$ northmostlat(-11.60')
has_of(PeruvianWatersRange, -12.40') $\wedge$ southmostlat(-12.40')
position(KHPosition) has_of(KittyHawk, KHPosition)
has_of(KHPosition, -12.22') $\wedge$ latitude(-12.22')
has_of(KHPosition, -77.50') $\wedge$ longitude(-77.50')
getlongitude(KHPosition)= -77.50' getlatitude(KHPosition)= -12.22'

Through axiom 3.3, axiom 3.4, axiom 1.1, axiom 1.2, axiom 1.3, axiom 1.4, axiom 10, we can get the fact:

-76.87'<-77.50'<-77.35' -12.40'<-12.22'<-11.60'

It is proved that these axioms are realistic. Some axioms don't write here. Obviously they can be proven because of the above proof.

Competency Revisited

In this section we repeat the competency and follow each with the query that would provide the answer. Note that parameters that are preceded with a "?" are variables. We also leave out the situational calculus predicates since all of the logical statements refer to the current situation.

- Which country doses the aircraft carrier x belong to (?c is the answer)?
  $build_by(x,?b) \wedge belong_to(?b,?c)$
- Which port does the aircraft carrier x stay at (?p is the answer)?
  $stay_at(x,?p)$
- Which ocean is the aircraft carrier x shipping in (?s is the answer)?
  $shipping_in(x,?s)$
- What is the longitude of the aircraft carrier x (?l is the answer)?
  $has_of(x,?pn) \wedge has_of(?pn,?l) \wedge longitude(?l)$
- Which aircraft carrier is at the position pn (?x is the answer)?
  $has_of(?x,pn)$
- What are the positions of the route points when carrier x carry out task t (?pn is the answer)?
  $carry_out(x,t) \wedge has_of(t,?r) \wedge has_of(?r,?rp) \wedge has_of(?r,?pn)$
- What is the northernmost latitude of area x (?nmlat is the answer)?
  $has_of(x,?ar) \wedge has_of(?ar,?nmlat) \wedge northmostlat(?nmlat)$

Conclusions

Ontologies are shared views of domains. They provide conceptualizations that are agreed upon by participants in collaborative action and decision making. The explicit existence of such shared perspectives makes it possible for people to communicate and cooperate.

The paper presents ontology for geographic information of aircraft carrier. With the help of this ontology, people will know more clearly about aircraft carrier. And reasoning geographic information of carrier by ontology can provide information about war. It helps leader analysis and decision.

Study on Utilizing Foreign Direct Investment in Underdeveloped Areas

Jianbo HU

Guizhou University of Finance and Economics, Guiyang 550025 China

email:hjbbo@126.com

Keywords: Underdeveloped Areas; Foreign Direct Investment; Performance Index

Abstract. The use of foreign investment is an important engine of developing inland opening economy. In 2012, in face of weak external demand, insufficient domestic effective demand and other serious and complex economic situation, the introduce of foreign investment in Guizhou keeps high growth , the actual use of foreign capital breakthrough $1 billion for the first time, up to $1.046 billion, growing by 55.35% year on year. The total amount ranked the sixth and the growth ranked the third in western regions. The utilization of foreign investment has realized the improvement of speed, quality and efficiency. The economic contribution of foreign investment to Guizhou has improved continuously, laying a solid foundation to accelerating the speed of economic development for Guizhou. But we also found many problems existing in the process of attracting foreign investment in Guizhou. And we need to seek reasonable countermeasures to further strengthen the role of foreign investment in promoting the economy of Guizhou and improve the core competitiveness of Guizhou to realize sustainable development of the economy.

Introduction

With the continuous development of economic globalization, International Investment is playing a more important historic role than any other time. As an important part of international investment, International Direct Investment (IDI) has an essential effect on promoting global economy. Since reform and opening up, China's foreign direct investment (FDI) has made great progress on both quantity items and amount in total, which has been driving GDP growth in China.Western regions where economic development are relatively backward in China, are also trying to attract FDI in various ways, trying to solve the "funding gap" and control the bottlenecks of slow growth of capital effectively. Therefore, introducing FDI has always being a strategic guidance for all levels of government in western regions to improve the level of local economic growth and the structure of the industrial development.Guizhou as less developed western region, is later than other provinces in China on introducing FDI. But in recent years, with national policies tilting to the western regions and expanding and improving opening to the outside world and the strategy of introducing FDI in Guizhou, introducing of FDI in Guizhou has advanced unprecedentedly both in the scale and quality.

The development status of FDI in Guizhou

1) Scale of FDI.There were total 53 industrial items from FDI enterprise in 2012, falling by 19.7% year on year. Thereinto:11 items of primary industry accounted for 20.75%, increasing by 83.33% year on year; 27 items of secondary industry remained the same year on year, accounting for 50.94%;15 items of tertiary industry fell by 54.55% year on year, accounting for 28.3%. Contracted foreign capital of FDI enterprise by industry was $573.83 million, falling by 66.4% year on year. Thereinto: contracted foreign capital of primary industry was $57.83 million, accounting for 10.08% of contracted foreign capital, falling by 33.27% year on year; contracted foreign capital of secondary industry was $306.66 million, accounting for 53.44%, falling by 63.81% year on year; Contracted foreign capital of tertiary industry was $209.34 million, accounting for 36.48%, falling by72.95% year on year. Foreign investment in actual use of FDI enterprise by industry was $1045.82 million in 2012, increasing by 55.35% year on year, and it ranked sixth in western areas, placed behind Chongqing, Sichuan, Inner Mongolia, Shanxi and Gansu. Its speedup ranked front

three in western areas. Contracted foreign capital which has been actually used of FDI enterprise was $491.16 million, accounting for 46.96%, falling by 4.70% year on year. According to statistics of department of foreign exchange control, foreign loan of the difference between investment and registered investment which has been actually used of FDI enterprise in Guizhou was $173.83 million, accounting for 16.62%; Domestic investment which has been actually used of FDI enterprise accumulated to $380.84 million,accounting for 36.42%. Thereinto; foreign investment which has been actually used of primary industry was $12.36 million, accounting for1.18%; Foreign investment which has been actually used of secondary industry was $688.25 million, accounting for 65.81%, among which foreign investment which has been actually used of manufacturing was $107.92 million, accounting for 15.68%; foreign investment which has been actually used of tertiary industry was $345.22 million, accounting for 33.01%. The industries of scale of foreign investment which has been actually used of tertiary industry ranked front five respectively; real estate, $224.84 million, wholesale and retail sale, $63.98 million, scientific research, technical service and geological exploration, $29.91million, leasing and business service industry, $15.08 million, information transmission, computer service and software industry,$5 million. Foreign investment which has been actually used of these five industries accounted for 65.13%, 18.53%, 8.66%, 4.37%, 1.45% respectively.

2) Means and structure of FDI.After reform and opening-up, every industry opened up to the outside world moderately and with measured strokes. Entering of foreign investment into every industry was somewhat limited at first, but with the deepening of reform and opening, the limitation was less and less. Foreign investment is allowed to enter into for most industries except for a few industries. At initial stage of reform and opening-up, foreign investment did not have enough faith in China because of little understanding. Foreign investment generally entered into Chinese market in the way of joint venture or cooperation for the sake of sharing risk. Although sole proprietorship can work on own and enjoy the benefit exclusively, but its risk was higher. Foreign businessmen would not choose singleproprietorship. Through more than 30-years' reform and opening-up, the growth miracle of Chinese economy is obvious to all. With the continuous enhancing faith of foreign businessmen to Chinese economy, single proprietorship has become the main way for foreign businessmen in China. As to Gui zhou, the transferring process of FDI ways is basically similar to the whole situation of our country. The items of Sino-foreign joint venture decreased from 18 to 4 from 2007 to 2010, and increased to 22 in 2012; FDI actual use is rising all the time, increasing from $42.88 million to $178.54 million from 2007 to 2012; The numbers of items of Sino-foreign joint venture is less than wholly foreign-owned enterprises all along. The items of wholly foreign-owned enterprises reached up to 31, FDI which has been actually used rises to $309.51 million, which is 1.73 multiples of foreign investment that has been actually used of Sino-foreign joint venture; Scale of Chinese-foreign cooperative enterprise is at a low situation. There were 7 items in 2010, even none left in 2012. The investment was only $3.2 million, which was far below other two investment ways.

3) Countries (regions) of origin structure of FDI.In view of the foreign investment by countries and by areas, we could find some facts. There were 42 enterprises in Asian countries (regions) invested Guizhou in 2012, downed 8.7% year on year; The value of contractual foreign investment were $384.84 million, downed 70.02% year on year; The actual use of foreign accounted $316.88 million, downed 21.89% year on year. There are 1 enterprise in European countries (regions) invest Guizhou in 2012, downed 75.00% year on year; The value of contractual foreign investment were $4.06 million, downed88.02% year on year; The actual use of foreign accounted $4 million, increased 41.84% year on year. There are 1 enterprise in South American countries (regions) invest Guizhou in 2012, downed 50% year on year; The value of contractual foreign investment were $1.58 million, downed 97.54%year on year; The actual use of foreign accounted $16.31 million, increased35.35% year on year. There are 1 enterprise in North American countries (regions) invest Guizhou in 2012, downed 75% year on year; The value of contractual foreign investment decreased $27.31 million, downed 122.47%year on year; The actual use of foreign accounted $58.26 million, increased 5.93% year on year. There were 1 enterprise in Oceania countries (regions)

invest Guizhou in 2012, downed 50% year on year; The value of contractual foreign investment were $0.63 million, downed 96.10% year on year; The actual use of foreign accounted $6.5 million, downed 30.11% year on year.

4) Industry structure of FDI.According to the FDI by industry, we could find some facts. There were 11 companies invest the agriculture animal husbandry and fishery in 2012, increased 83.33% year on year; The value of contractual foreign investment were $57.83 million, downed 33.27%year on year; The actual use of foreign accounted $7.55 million, downed 90.79% year on year. There were 3 companies invest The mining industry enterprise in 2012, increased 50% year on year; The value of contractual foreign investment were$36.77 million, increased 96.11%year on year; The actual use of foreign accounted $4.5 million, downed 38.94% year on year. There were 20 companies invest Manufacture in 2012, increased 25% year on year; The value of contractual foreign investment were $237.79 million, downed 56.99%year on year; The actual use of foreign accounted $51.79 million, downed 74.21%year on year. There were 3 companies invest electricity, gas and water production and supply industry in 2012, downed 57.14% year on year; The value of contractual foreign investment were $30.68 million, downed 80.20%year on year; The actual use of foreign accounted $81.88 million, increased 11.71%year on year. There was 1 company invest construction industry in 2012, downed 50% year on year; The value of contractual foreign investment were $1.42 million, downed 98.82%year on year; The actual use of foreign accounted $53.28 million, increased 25271.43%year on year. There was 1 company invest Transportation, warehousing and postal service in 2012, the value of contractual foreign investment were $80.53 million. There were 3 companies invest wholesale and retail sales in 2012, downed 57.14% year on year; The value of contractual foreign investment decreased $11.6 million; The actual use of foreign accounted $25.26 million, increased 115.53% year on year. There was 1 company invest real estate in 2012, downed 80%year on year; The value of contractual foreign investment were $4.83 million, downed 98.03%year on year; The actual use of foreign accounted $224.84 million, increased 889.61%year on year. There were 6 companies invest leasing and commercial service in 2012, downed 40%year on year; The value of contractual foreign investment were $123.14 million, downed 55.88%year on year; The actual use of foreign accounted $5.48 million, downed 91.34%year on year. The actual use of foreign of scientific research, technical service and geological prospecting industry accounted $29.91 million, increased 50.86%year on year. There was 1 company invest water conservancy, environment and administration of public facilities in 2012, downed 66.67% year on year; The value of contractual foreign investment were $640000, downed 98.40%year on year; The actual use of foreign accounted $640000.

Problems in the Process of Guizhou's FDI development

1) Small investment scale and inferior quality.As we can see from the absolute number, the ranking that amount and the number of enterprises of Guizhou's FDI is lower in 31 provinces. For example, in 2012, number of entry and contract amount that Guizhou used were reductive. Number of entry only accounted for 0.21%, and actual foreign capital Guizhou used only accounted for 0.44% over the country. Although the actual foreign capital increased a little, the total amount only accounted for the sixth in western region. As we can see from the relative number, maybe we can show with a Inward FDI Performance Index (IND) of foreign capital that a district attracted. (IND) means that in a certain period, the proportion that a region's FDI inflow accounted for the country's was divided by the proportion that the region's GDP accounted for the country's, which can be showed with mathematical formula as in (1):

$$IND_i = \frac{FDI_i / FDI_n}{GDP_i / GDP_n} \tag{1}$$

Thereinto, i represents a certain province , n represents all provinces of the country, That is n=1,2,...,31; if the greater a region's economic scale is, the more FDI that a province attracts is, so

the more close to 1 IND is, on the contrary, the more close to 0. According to the above formula and the relative dates of Guizhou's FDI, we can solve IND of Guizhou in recent years, the details are shown in table 1. In the table, all IND are below 1, and the most of IND is lower than 0.2, which shows that the promote force of FDI to Guizhou's economic development needs to be improved, and further shows that the proportion Guizhou using FDI is on the low side, so Guizhou still needs to further increase the intensity of introduction of foreign capital.

Table.1 Inward FDI performance index in Guizhou from 2007 to 2012

	2007	2008	2009	2010	2011	2012
Actual use of FDI in Guizhou ($0.1 billion)	1.27	1.49	1.34	2.95	5.15	4.91
Actual use of FDI in Chia ($0.1 billion)	747.7	924	900.3	1057	1160	1117
proportion that FDI in Guizhou accounting for China （%）	0.17	0.16	0.15	0.28	0.44	0.44
GDP in Guizhou (0.1 billion yuan)	2884	3562	3913	4602	5702	6852
GDP in China (10 billion yuan)	2658	3141	3409	4015	4731	5189
The proportion that GDP in Guizhou accounting for China（%）	1.08	1.13	1.15	1.15	1.21	1.32
IND of FDI in Guizhou	0.16	0.14	0.13	0.24	0.36	0.33

Data sources: the information is calculated and sorted according to the relative data of China Statistical Yearbook in 2013 and Guizhou Statistical Yearbook .

2) Higher utilization of foreign capital in individual industries and regions, and unbalanced distribution of development.One is that the distribution of FDI industry is unbalanced. In addition to the individual year, investment proportion of FDI in the primary industry was larger, the other years' was less, and it showed no continuity, which indicates that investment of FDI in agriculture is less and no obvious endurance; For a long time, the FDI investment mainly concentrated in the second industry, and especially in the manufacturing industry. The average capital investment of FDI in the third industry accounts for about 30%, but since 1992, the amount of investment to the third industry presents the obvious increasing trend, by 2012, which has been more than the second industry, mainly concentrated in the real estate, scientific and technical services, geological prospecting industry, finance, insurance and so on; in 2012, the ratio between the number of three times industry and the actual investment of foreign capital was 20.75: 50.94: 28.30 and 1.54: 38.98: 59.48. The Second is that the regional distribution of FDI is not unbalanced. FDI exists in every city in Guizhou, but it is not uniformity. Guiyang accounts for the highest proportion, for example in 2012, the number of new signing projects, the actual use of foreign capital and the investment amount of foreign merchant's agreement respectively accounted for 23%, 31.5% and 39.4% of the whole Guizhou. And in the 9 cities and states, the actual investment of foreign capital in Guiyang was more than one third, which played a leading role; the amplification of actual use of foreign capital in Tongren and other cities and states was larger, but the gap between Guiyang and the other cities and states did not shrink, and the actual use of foreign capital scale in mountainous and hilly region was smaller, and such imbalanced situation was bad for comprehensive and balanced development of Guizhou's economy.

3) Foreign capital of country of origin comparative intensively, Euramerican foreign businessmen investment on the low side.FDI enter into Guizhou on a large scale, which has become one of the important sources of capital accumulation, promoting rapid growth of stock of agent of production effectively, and then pushing Guizhou economic sustainable growth to a large degree. However, highly centralized source of FDI make Guizhou be influenced easily by international economic cycles and bear higher risk. Since affected by original industry base, Guizhou competitive industries concentrate on resource-integrated industry, labor-integrated industry, resource processing and so on. High processing industries develop deficiently, and added value of industry products is one the low side. Comparing to eastern province, tertiary industry develops evident laggingly. For example, in 2010, tertiary industry accounts for 36.4% in Chongqing, 46.1% in Tianjin,57.3%in Shanghai, 75.1% in Beijing, but only 26.4% in Guizhou. Modern service industry

in Guizhou. Develops laggingly, financial environment is not perfect, research and development ability is weak, new high-tech industry develops slowly, causing Hong Kong to become the main source district of foreign capital in Guizhou, and European and the United States foreign capital is short for it requests environment higher. Taking 2010 as an example, a new body of foreign-investment enterprise in Guizhou mainly concentrates in Hong Kong, Taiwan,Malaysia, items of which are 29, 4, 3 respectively, accounting for 67.92% of total items; Contracted foreign capital concentrates in Hong Kong, reaching up to $334.56 million, accounting for 58.3% and surpassing half; Contracted foreign capital which has been actual used mainly concentrated in such as Hong Kong, Bermuda, British Virgin Islands, Singapore, capital which has been actually used is $296.28 million, $56.45million, $13.61 million and $9.99 million respectively, the total capital that above-mentioned capital plus accounts for 76.62%.

Measures of accelerating the utilization of FDI in Guizhou

1) Try to perfect the policy on industry development and strengthen support and guidance on accelerating development of foreign capital.According to the Catalogue for the guidance of foreign investment industries and catalogue of priority industries for foreign investment in central and western regions promulgated by the state council and the file spirit of the western development and acceptance the industry transfer, we should consider about the actual of Guizhou, enlarge the support of attracting foreign capital policy and strengthen the 12th five-year development strategy planning in order to lead the foreign investment into modern agriculture in Guizhou and promote the industrialization of agricultural effectively. Encouraging foreign investment into native, advantageous and capital and technology intensive industries of Guizhou, and setting up production bases and research and development centers should also be done. Perfecting foreign participation in the high-tech industrialization and establishing open type autonomous innovation system of policy measures is also necessary. We should pay attention to increase state enterprise restructuring intensity and boot foreign investment into Guizhou state enterprise of technology and assets restructuring and optimize state enterprise capital structure. Try to research and develop the policy measures of improve zone competitiveness, achieve transformation upgrade and sustainable development. Perfect foreign investment established venture investment enterprise and equity investment enterprise of policy and control effectively "three high" (high energy, and high pollution, and high emissions) industries of blind investment; vigilance based facilities of repeat construction and the ahead construction; strictly according to national industry policy and the acts about foreign investment , we cannot blind mention some unrealistic of "leap" type of slogan blindly or act in incessant movements to deal with the investment and construction, then promote economic prosperity in Guizhou’s cities and states.

2) Try to guide foreign investment into cities and states and promote regionally balanced development of foreign capital.As the seat of the capital of Guizhou, Guiyang whose economy is more developed and investment environment is superior, with strong appeal to foreign investment has always been the preferred destination of foreign investment while investing in southwestern, the southeast and the south areas in Guizhou has less foreign investments. Continued to maintain the advantages of absorbing foreign capital, Guiyang, should also optimize the expanding foreign investment actively. Foreign investment in Guizhou in a long period of key industries including: agriculture, infrastructure construction, high-tech industry, energy, environmental protection and raw material industries, urban facilities upgrading and tertiary industry. Introduction of the high-tech industry, basic raw materials industries and service work should be combined with the adjustment of industrial structure in Guizhou and modern enterprise system reform. Relevant government departments should gradually reduce the introduction of labor-intensive capital, with a focus on developing high-tech industries such as electronic information, bio-pharmaceuticals. While, government sector should effort to improve traffic, and communications, and water, based facilities conditions in Guizhou southwest, southeast, and the south areas and constantly perfect investment environment, adjust industry structure, improve industrialized level, increase publicity intensively in order to create good conditions to attract foreign capital , boot foreign investment from center

city to around areas actively and promote the balance development of foreign capital in each city in Guizhou.

3) Optimizing the industrial structure of investment attraction and accelerating the development of service outsourcing.It is supposed to actively undertake industrial transfer, and promote a further opening-up and optimization and upgrading of industrial structure together, besides, Taking the initiative to undertake industrial transfer abroad is beneficial. Apart from that, it is seizing the opportunities of global industrial restructuring, relying Guizhou resources, comparative advantage and industrial base markets that can put various development zones carrier and platforms into full play and can optimize the conditions of the business environment and supporting industries. Also, focusing on undertaking modern agriculture, high-end manufacturing, high-tech industries, modern service industry, new energy and energy-saving environmental protection industry transfer are firmly important. Moreover, it is a must to boost the related service institution and the innovation of government regulation, to make special economic function areas (such as Guiyang Comprehensive Bonded Zone) become a big platform facing the international market to develop service outsourcing industry so that government can enhance their own capacity in Guizhou service outsourcing industry and strengthen the service outsourcing talents education and training. Both taking every effort to train local service providers and undertake location services are equally essential. And actively guide the medium-sized state-owned enterprises and private enterprises with strength to participate in this process in order to deepen the division of labor, and strengthen self-service subcontracting as its starting point, and then will be able to constantly improve the level of participation in domestic and international division of labor services. Through enhancing the level of cooperation by multinational corporations, promoting the core competitiveness of local service levels, ultimately, it can facilitate a number of local outsourcing providers to success.

Keywords: English test, computer, reliability, validity

Abstract. With the rapid development of computer technology, the computer has rapidly entered our daily life. People begin to use the computer for scientific research, production, entertainment, and information consulting and other activities widely, which brings about the Computer Aided Designing, Computer Aided Manufacturing, Computer Aided Instruction in order to improve the efficiency and quality of life. Using computer technology in language testing has become the trend of language testing both at home and abroad. Communicative language teaching becomes the guiding ideology and theoretical basis of modern language testing. The reliability and validity in computerized language assessments have become the two important criteria of evaluation of test quality. Computer Assisted English test with its unique advantages has opened up a new heaven and earth for English test.

Reliability and validity

Reliability of language testing refers to the reliability of the results, which means whether the test results is relatively stable or not. If the results of a set of questions tested today compared to a few days later are consistent, the reliability of the questions is high. The scale of the reliability of language testing mainly reflects the actual language behavior. There are many factors which can affect the reliability; they exist in every link of language testing.

Validity is a kind of correlation, indicating the connection degree of the test and objectives of the test. Generally speaking, if a set of questions measures what the designers want to measure or test about content or ability, then this is a test with high reliability and validity. According to the traditional explanation of structuralism, validity of language testing refers to whether it takes an examination of the test.

The reliability of language testing explains the relationship between examination results and language behavior. No reliability means that the test results are not credible and are not the real reflection of the examinees' language behavior, according to which is difficult for us to measure anything. With no validity but only the reliability of the test is meaningless, because it accurately measured the not related or unrelated things with language ability. In this case, we can't speculate the true language ability of these examinees from the test results also. To achieve the purpose of a language testing, reliability and validity are both required, which are the unity of the two relations.

The guiding ideology of computer aided English testing.

To design a good Computer Aided English Testing System and to improve its reliability and validity, we must have a basic understanding of the development of its guiding ideology and theory. The US education testing service put forward to establish a new English Testing System based on cultivating communicative ability. Obviously, this sets CLT (communicative language teaching) as the basic guiding ideology and theoretical basis, a new test model of communication skills to test candidates. CLI was brought about in 1960 ~ 1970 s by the British linguistics, it greatly improves the efficiency of language teaching and the learners' learning because it completely abandoned the previous thoughts that were putting emphasis on the mastery of language knowledge, and focusing

on calculation and improvement of the communicative competence, and thus has been widely accepted and promoted.

Communicative language testing includes communication ability such as grammar, discourse and social language ability and strategy ability and by the truth to make the candidates clearly handles language information and the implied meaning or function at the same time. Computer Assisted Language Testing is a new exam system based on the communicative competence, which is a kind of examination setting Communicative Language Teaching as the basic guiding ideology and theoretical basis, and its main purpose is to test actual communication skills of the recipients.

Testing models assisted by computer.

Use computer technology to test is a supplement to traditional language testing means. It can make up for the defect of system model and improve working efficiency to some extent and can achieve paperless test.

3.1Online testing model.

Online examination is suitable for large-scale network. After designing the test, the tester will compile the questions into database and put in the Data Server as stipulated. When examined, examinees enter personal information first, and then answer questions. When time arrived, it will automatically end the exam. Some tests just have objective questions, it can show examinee's score immediately, and print statements and the related certificate according to their need. In the future, examinee may use the form of dial-up in their own home to take the examination. If there is a large enough database and the questions have been dealt with certain difficulty processing, every time the examinee takes a test, computer can automatically generate a set of questions. So, the test can open all the year round, examinee can be flexible to arrange the time according to their own conditions.This will greatly improve the processing speed of the examination paper, save time and energy for reading; lower the error rate to zero. if the detailed performance statistics are not issued on the spot, it can also be sent to students via email quickly.

3.2PC testing model.

For the usual class test, phase test and homework test, the most feasible way is standalone software test. Questions are designed by the teacher on the special software. Students take the disk to attend the exam in a unified computer classroom or to test at home or at friend's on computer easily. Due to the same time that the software gives each student to answer, test is fair on the whole. Then, students hand the disk back to teachers, who read through the test software which actually done by computers and gives teachers the statistical report of the results. Stand-alone software test can reduce teachers' workload, increase students' interest in subjects, and can also greatly reduce the cost of printing papers. It has a very practical effec for all levels of the teaching unit.

3.3Unique advantages of the computer aided English testing.

With the development of English teaching reform, the use of multimedia network source to strengthen students' listening and speaking skills has become a important task in English teaching. Computerized test has gone through many forms, is born with the characteristics of dynamic, intuitive, image.

Problems can use words, pictures, voice or video or other forms to let the examinee maximum show their language skills and interpersonal skills within the given time. The computer aided test can not only check the basic language such as grammar, voice quality of the candidates, but also can test the examinees' speculative ability, understanding ability, personal skills and the understanding of the culture both at home and abroad, the grasp of the English idioms and interpersonal communication in foreign language etc. All in all, realizing the modernization of language testing and pick up with the world are the trend of the Times, are also the only way to our English test reformation in the future and improvement of the quality of foreign language teaching. Computer aided teaching may make students understand easily, especially difficult math. For example, some functions can be drawn to pictures and set math model such as **$y=a+bx$, $1/y=a+b/x$, $y=(x^b)$, and $y=a(e^{b/x})$ est.**

FFT and CAT.

FFT is face-to-face test, which examinees take test when the teachers are present and monitoring. CAT is computer aided test, which examinees take test on the computer.

Chart 1

	Average	Mode	Twin Tail	Minimum	Maximum
FFT	78.755	81	0.312	39	98
CAT	77.675	80	0.312	33	96

We see from chart 1 that the average grade of the FFT is higher than CAT. And chart 1, chart 2 and chart 3 show that CAT has higher discreteness while FFT has a trend to centre, among which the grade of 70-89 accounts for 85%, while 60-69 only accounts for 5% and more than 90 accounts for 8%. Compare to FFT, CAT is more reasonable. CAT system helps reduce the judge for scoring reliability of subjective factors, therefore, the result is more scientific and reliable.

Chart 2

Scores	<40	40-59	60-69	70-79	80-89	>90
FFT	2	1	6	51	62	12
CAT	1	1	23	40	46	23

Chart 3

	Reading	Question 1	Question 2	Discussion
FFT	0.65	0.72	0.77	0.75
CAT	0.70	0.69	0.75	0.71

Improving the reliability validity of computer-assisted English test.

Training the examiner before the test is a useful way to guarantee the reliability and validity. Examination is a kind of education measurement. For the so-called measurement, the first thing to have is a standardized measuring tool; then people who use the measuring tool should be able to maintain the consistent standards. If computer-assisted language testing examiner want to achieve this, the examiner must have a consistent view on the measured language ability, have a consistent understanding on scoring criteria, and grasp the scoring criteria consistently. Language testing is not only a performance test, but also a proficiency test, because the fundamental purpose of the test is that student learn through specific textbook content finally learned the content and form a kind of ability, both language ability and auxiliary language understanding and expression of language ability. This kind of reliability is indispensable to any kind of exams and is an important feature in any exam, otherwise the examination results will not be able to accurately reflect the real examinee's true ability.

Summary

Facing the trend of computer aided language testing at home and abroad, to design good Computer Aided English Testing System, improve its reliability and validity need designers and managers of the Computer Aided English Testing System to understand and grasp the guiding ideology and theoretical basis of modern language testing, at the same time, do more research and exploration in the examiner training and the quality monitoring of computer aided testing marks. Only with the validity and reliability of test, will the exam reflect the real level of the examinee and promote the development of English teaching.

Comparative Analysis of the Professional Situations and System of Television Basketball Commentator in China and America

Fan Yanwei, Fan Xiao

Physical Education Department of Ji'nan University, Guangzhou, 510632

Keywords: television basketball commentators; China; America; comparative analysis

Abstract. As unique scenery when the fans are appreciating high-level basketball matches through television signals, the television basketball commentators stand as an excellent channel for the fans to better and carefully appreciate the matches and to learn the information in and off the court. By means of document and data and comparative analysis, this thesis makes an analysis of the professional situations and system of television basketball commentator in China and America. Finally, it arrives at a conclusion that compared with those in America, Chinese television basketball commentators have huge gaps in many aspects, especially that the professionalization of working system urgently requires improvement and enhancement.

Basketball matches in China are growing energetically. Every year, hundreds of high-level basketball matches from China Basketball Association and China University Basketball Association are held significantly. In the meantime, on the other coast of the Pacific Ocean, countless high-level matches are held in America, and the so-called "the kingdom of basketball" and NBA (National Basketball Association) have been universally recognized as the professional sports event with the highest competitive level and appreciation values. It is the basketball matches of the highest level all over the world, including Olympic Games and the World Basketball Tournament that become the necessities for Chinese basketball fans. In order to satisfy the large demands from fans, every year, live broadcasting of numerous basketball matches prove to be materialized by CCTV-5. Different local stations and online channels enable the Chinese fans to watch high-level basketball matches closely, learn match process and characteristics in time and cheer for their own favorite teams, in all of which the television commentators play a crucial role. A qualified commentator requires the ability to allow the fans to learn information in and off the court at all aspects more comprehensively, watch the matches more intensely and enjoy an on-site experience and a long aftertaste of the matches.

The current era in which the electronic media constitute the mainstream is replete with internet information. The basketball matches are becoming more and more worth appreciating, in that the spectators include basketball fans as well as experts in basketball teaching, training and researching. They collect information by all means, conduct further researches in sports and athletes and possess rich first-hand materials comparable with those possessed by television commentators. Meanwhile, along with the results of the matches no longer as the single focus, it proves to be the major content to analyze matches from all perspectives and track the latest life information and details of teams, player and caches, all of whom gradually bring basketball matches back to their complex and diverse ontology plane and the diversification edge of the entertainment. Therefore, the traditional "know-all" television sports commentators fail to meet higher requirements from audiences and it will be a mainstream for the professional basketball commentators to commentate matches. Compared with the professionalized and specialized American basketball commentators who enjoy profound professional basis and commentating capacity, the Chinese basketball commentators encounter gaps at the following major aspects.

To Compare Chinese And American Basketball Commentators From The Perspective Of Composition

Most commentators in China come from the channel of CCTV, different local television stations and network channels. Most of them prove to be broadcasters or prove to major in sports news, including Yang Yi, Su Qun and Sun Zhengping. In the meantime, a minority of commentators

possess professional sports background, including Zhang Weiping (former main power forward of Chinese National Basketball Team) and Xu Jicheng (former player of Beijing Military Area Basketball Team). From time to time, some high-level professional athletes or coaches are invited as the commentary guests, for instance, Yao Ming and Wang Shipeng were invited as the commentary guests in the 2011 Wuhan Asia Championship for Men and some domestic famous basketball characters including Li Nan and Zhang Jinsong. Two former players of Rockets, Wang Fei, the chief coach of Zhejiang Guangsha, were invited as the commentary guests during the broadcasting of CBA matches; however, few commentators who have commentated basketball matches with rich professional basketball experience are available, due to which some conspicuous basketball tactic mistakes during commendation would occur and mislead the basketball fans.

A large number of NBA commentators turn out to be former prestigious NBA stars, coaches or team accompanying staff, including "Evil Bird" Charles Barkley, former player of Phoenix Suns, Reggie Wayne Miller, former player of Indiana Pacers and "the Glide" Clyde Drexler, former player of Huston Rockets. After their player career in NBA, they gradually became well-known NBA basketball commentators and Barkley had been laughed at by the fans across the world since kissing the ass of a donkey due to losing the bet that Yao Ming would never score over 19 points in his first year in NBA. Van Gundy, former chief coach of Huston Rockets, the team Yao Ming once played for, becomes an outstanding NBA commentator after his coach career.

Thanks to energies required in professional basketball matches and their own tolerable language talents, with professional systematic trainings, these players or coaches prove to be commentators of the basketball matches at will. What's more, some "professional" basketball commentators would drop some comments on their own sporting experience at intervals, which turns out to be fans' favorite thing.

To Compare Chinese And American Basketball Commentators From The Perspective Of Commentating Style

Excellent commentations would allow the adrenal hormone of fans and players to soar in a short time. On the contrary, however, monotonous ones would devitalize the exhilarating matches. Therefore, it is not uncommon for us to notice that some fans would like to watch a match for a specific commentator while some would turn off the sound of the TV when they are watching the matches. With every commentator characterized with his or her own personalities, Chinese and American commentators bear huge differences in commentating styles. As for American television commentators, individuality is encouraged so that some incredible actions would be presented during the commentations; nonetheless, most Chinese commentators prove to be modest and prudent, and they could always provide their audiences with soul-stirring feelings at the vital moments.

Local television stations in America are characterized by typical American style and the resonant American pronunciation accords with the court atmosphere perfectly; nevertheless, it can be easily found out that most commentations broadcast by local stations prove to be descriptions for the matches. Some commentators are used to commentating energetically. For instance, once they are invited as the commentators of ESPN, Bill Walton looks like an extremist and feels like employing a series of words to express one opinion powerfully and vigorously. By comparison, in American commentating field, Charles Barkley from TNT turns out to be more explosive in that he frequently displays some unbelievable actions. Apart from the coexistence of steady and profound academism styles, for example, Hubie Brown from ABC television station seems to pay more attentions to "rationalness". With unparalleled understanding of basketball, old Brown would endow anyone sitting beside with basketball knacks within a short period of time. During the prudent and humorous commentating, Van Gundy successfully gets himself "vampire eyes" with his pervious experience as a basketball coach.

Chinese television commentators tend to attach more attentions to the style of a team, the backgrounds of the players, as well as the tactics. Unique styles have been formed in Chinese commentations which can be exemplified by CCTV. Among all CCTV-5 commentators, Sun

Zhengping might be taken as a has-been while Yu Jia and Yang Jian present outstanding commentations; with regard to the commentary guests, with plain languages, Xu Jicheng is as kind as a senior who watches the matches over drinking tea; humorous and exhilarating, Yang Yi is quite familiar with the overall information of NBA and presents audiences with well-organized and logic commentations or bombing words and expressions. Home at the basketball knowledge, Su Qun, the chief editor of *Basketball Pioneers*, has conducted numerous highly professional interviews in NBA All-stars and finals; at the time when it comes to the professional level of domestic men's basketball commentations, Zhang Weiping turns out to be second to none, due to which he has been entitled to "rational tutor" by his fans out of the good will. During the commentations, Chinese commentators apparently tend to give emphasis on the explanations of tactics, as well as the analysis of players' actions.

Differences Between Chinese And American Working System Of Television Basketball Commentators

China has witnessed an immature selection and evaluation system for television basketball commentators, most of who suffer from the low professionalization due to undertaking commentations for other sports. Professional basketball commentators prove to be peculiar to CCTV in that all CBA teams possess no television basketball commentators and there are only three local television stations, including Beijing, Shanghai and Guangdong Province that are equipped with their own professional television sports commentators. All of them have to be commentators of other sports at the same time and sometimes invite the assistant coaches or retired players as the commentary guests. With profound basketball knowledge, these guests can not become qualified television basketball commentators without systematic knowledge and professional training of being commentators.

Each team in NBA employs its own professional basketball commentators to commentate matches at local television stations. For instance, Clyde Drexler, former player of Huston Rockets became a basketball commentator for Huston Rockets after his retirement and he made commentations of numerous matches of Yao Ming. Having been working for his team for 27 years, Brad Davis, commentator of Dallas Mavericks, is quite familiar with the players and coaches and from time to time blurts out some novel punch lines. In America, all local television stations possess their own professional basketball commentators. Once establishing Bulk Dynasty together with Micheal Jordan, Steve Kerr used to be a commentator at TNT television station to offer on-site feelings for the audiences with his rich court experience. Thanks to the long-term company with the teams, their professional experience in NBA as players and constant commentating, they enjoy a high level of professional commentations.

Differences In Payments For Television Basketball Commentators In China And America

There exist huge gaps when it comes to the payments for television basketball commentators between China and America. While being invited as commentary guests in Wuhan Asia Basketball Championship for Men, Yao Ming and Wang Shipeng received 500RMB, which proved to be incomparable with the payments of CBA professional players. As the commentary guests for CCTV in CBA matches in 2008, Wang Fei was paid over 3000RMB in total after a half of the season, which even proved to be lower than the salaries of workers in some private enterprises in south China. Therefore, it turns out to be rather difficult for them to attract the domestic basketball elites to commentate matches with such low payments.

The author came across Josh Brown, a consultant invited by China's Basketball Association and former television basketball commentator for a certain NBA team at a CUBA summer camp, who revealed to the author that in America commentation payment for one match was 5,000 dollars and as for NBA celebrities, the payment could be higher. For instance, Van Gundy, mentor of Yao Ming signed a five-year contract with ESPN, with the annual salary as 1.2 million dollars (nearly 7.6 million RMB) which required CCTV commentary guests to commentate 15,320 matches. Charles Barkley, a TNT commentator and NBA celebrity obtained an annual salary of 1 million dollars

(nearly 6.4 million RMB) while those with narrow reputations, including Mark Jackson and Jon Barry, could receive an annual salary of 600,000 to 800,000 dollars. Compared with 50,000 dollars, Americans' average annual salary, proved to be much higher, though far lower than that of the NBA stars. Therefore, plentiful payments attract more stars and celebrities to commentate, due to which more fans would like to watch live broadcastings.

Conclusions and Suggestions

A. Conclusions

Compared with television basketball commentators in America, Chinese television basketball commentators possess their own job category and commentation characteristics, both of which play a vital role in enabling the basketball fans to better appreciate the basketball matches. Here are the specific conclusions as follows:

• China and America differ greatly in the sources of television basketball commentators. Speaking it more concretely, Chinese commentators are mainly engaged in professional news media, and few of them have possessed professional experience; however, most American commentators are retired players or accompanying staffs from NBA teams, who constitute the majority of American commentators. Their professional level in basketball and professionalization of commentation are absolutely higher than those in China.

• Both Chinese and American television basketball commentators enjoy their respective commentating styles. The commentators China are relatively more prudent and serious, while those in America are alive with their characteristic individuality, which can be mainly explained by their differences in the cultural landscape.

• The working system of China's television basketball commentators proves to be partially professionalized than that of America in that as professional commentators. Most commentators in America are professional, who engage themselves into basketball commentating all year round; however, in China, and the vast majority of the commentators are temporary or part-time commentators who are players or coaches invited from CBA teams. This is quite common phenomenon in China.

• Compared with that in America, the payment of Chinese basketball commentators proves to be rather low, which differs greatly from that in America. It is really difficult to employ the retired players or coaches from CBA or other high-level basketball leagues. It is directly influencing the professional grade of commentators.

B. Suggestions

• It requires Chinese television basketball commentators to fulfill their own commentating personalities on the condition that the modesty and prudence are maintained so that more basketball fans can be attracted by their unique styles. They should give full play to their individuality in being a commentator so as to attract more and more fans.

• China should further specialize and professionalize the working system of television basketball commentators. In the meantime, all local television stations should also employ the corresponding professional commentators, in order to satisfy the infinite demands from all of the fans of basketball.

• The payment of professional television basketball commentators in China must be increased to a higher level, so as to attract all kinds of elites with professional basketball experience to apply for commentating. In this way, the overall level of China's basketball commentating can be further improved and enhanced to a higher level to better serve the fans.

The impact of RMB appreciation on the sporting goods industry and Countermeasures

Fan Wei Yan , Fan Xiao

Sports Ministry, Jinan University, Kaifeng 475001

Keywords: domestic currency appreciation; sporting goods industry; effects and countermeasures

Abstract. This paper uses literature survey and online survey to analyze the reasons for the appreciation of the currencies and its impact on the sporting goods business in China. It proposes a few strategies for the companies to deal with the appreciation such as: Restructure the finance and manage the foreign currency debt effectively; utilize the oversea resources to reduce the production cost; improve the added value to the products, increase the investment in the research and development, follow the brand and sales strategy and become more competitive.

Objective

Exchange rate is an important international financial issue closely related to national economy. The fluctuation can have significant impact on the international trade. Since China adopted the reform policy, the rapid development of China's foreign trade surplus

Has accumulated a large reserve and exert unprecedented pressure on RMB appreciation. As Chinese sporting goods industry heavily rely on exports for its growth, the RMB exchange rate is critical. They need to comprehensively understand the impact of the RMB appreciation and make timely changes in terms of resource allocation and sales, restructure the business.

Research Methods

2.1 Literature survey

Through journals, newspapers and other books, we gained more information about the RMB appreciation and investigated on both the positive and negative impact of currency appreciation on the sporting goods industry.

2.2 Field survey

We visited Zhejiang, Fujian, Guangdong and other sporting goods manufacturing centers and sent out questionnaires to 80 companies, among which 74 were recovered (the effective recovery rate of 92.5 %).

2.3 Online information query

The reference material we found online include State Sports Information Institute's "foreign sports information database", China Sporting Goods Association's "Sports Information Network China". From them we can better understand the sporting goods industry, changes in operating conditions and the impact of the exchange rate.

Results and Analysis

3.1 The reasons behind RMB appreciation

As U.S. still dominates the world economy, the fluctuation of the U.S. dollar exchange is a top news for the world finance. From the historical peak of 0.8 euros, the dollar decline against the euro has accumulated more than 60%. As a result of pegging the foreign exchange rate to the dollar, the yuan against other major currencies depreciated indirectly[1]. For a time, from their own interests, the United States, Europe, Japan, all advocated to revalue Yuan. And the rumors on the new exchange policy for the RMB kept on coming, while the non-deliverable forward contract (NDF) discount rate reached record highs. China exchange rate policy became the world top attention.

3.1.1 RMB appreciation is due to decreased U.S. dollar value

The depreciation of U.S. dollar is caused by the market worries of the large US debt and the rapidly deteriorating current account deficit. America has always been a high consumption, low savings country. Therefore, the current account deficit inevitably accompanied the huge budget deficit. When Bush took office in 2001, there were $127.3 billion federal fiscal surplus, but after the large-scale tax cuts, the economic recession led to revenue decreases, and the war on terror further increased the financial expenses dramatically. The financial situation deteriorated rapidly. In fiscal year 2004 , the federal deficit reached $ 413 billion. In addition to these two points, the U.S. dollar was also affected by the impact of direct investment. In 1999 and 2000, foreign direct investment in the United States reached $ 283.4 billion and $ 314 billion; but then the world's direct investment went to a low ebb, and the amount was significantly reduced, by 44.9% from 2002 to 2003. As U.S. current account imbalance becomes more severe, the pressure on a cheaper dollar has increased.

3.1.2 The inflation pressure

Recently a large number of speculative capital flew into China's financial markets, betting on RMB’s appreciation. The rapid increase can be seen from China’s foreign exchange reserves since 2003,. Over a long period of time, China's capital flight had been a problem. Although there were huge trade surplus, the amount of foreign exchange reserves did not reflect the growth of these "surplus". Since 2003, even if the surplus did not increase as much, foreign exchange reserves climbed up really fast. Customs statistics showed that in the first eight months of 2004 China's total trade surplus was $8.86 billion only, but according to the Bank of China’s statistics, September 2004 alone saw China's foreign exchange reserves increasing by $183.69 billion. As of end of March 2005, China's foreign exchange reserves reached $659.1 billion and broke a new record. Under the mandatory sale of foreign exchange, large amount of dollars were sold to the central bank, and the central bank had to pay 8.28RMB to each dollar. As RMB were circulated, inflationary pressure followed.

3.1.3 The internal dynamics within the economic system

The major internal factors for Chinese economy include foreign exchange reserves, inflation, price levels, balance of payments, interest rates and economic growth conditions [2]. The RMB appreciation would help alleviate the “overheating" of the economy. In certain circumstances the currency appreciation pressure can be converted to inflationary pressure and help get rid of the fixed currency model, preparing for yuan to become the world's hard currency. It is also an opportunity to narrow the difference between the RMB and the Hong Kong dollar for the gradual transition to 1:1, and in due course, the yuan, the Hong Kong dollar, the Macao dollar can be integrated to form a single currency.

3.1.4 Historical Reasons and External Pressure

Between1994 and 2004, the RMB exchange rate had not been adjusted for 10 years. Since then, China began to implement a managed floating exchange rate system and officially ended the pegging system. China resumed the pegging during the recession but eventually let it flow again. In the last ten years China's economy has undergone profound changes. The trade surplus got too large, and foreign exchange reserves got excessive due to the payment imbalances. RMB appreciation is unavoidable. In addition, since 2001 currencies in all major Southeast Asia countries have been greatly appreciated against dollar, and RMB was devalued as it pegged to the dollar. After joining the WTO, the trade surplus further increased as China exported a large number of cheap goods all over the world and affected the domestic labor markets. For example, US government has elevated the currency issue to a key political issue, hoping to use RMB appreciation to limit Chinese imports.

3.2 The Impact of the exchange rate fluctuation on the sporting goods business

3.2.1 RMB appreciation affected the export significantly

China's sporting goods companies are mostly focused on production only, in the processing trade, and in the middle of the smile curve, playing the production role in the global value chain [3]. Currency appreciation brings into less domestic currency. Coupled with price increases and high

inflation, exports almost have no profit and even have to suffer losses. Many companies are not willing to accept orders and having hard time to continue with their productions.

3.2.2 RMB appreciation can help the companies to repay the foreign debt

Since the exchange rate reform, the RMB against the U.S. dollar dropped from 1:8.7 to 1:6.34 (December 2011), which is very beneficial for companies bearing foreign debts. they should delay the repayment time, to increase the amount of foreign debt purchases, to reduce debt costs. Data shows that RMB appreciation can inhibit the inflow of foreign capital, which includes foreign direct investment and foreign borrowing to debt.

3.3 RMB appreciation is conducive for direct trade to foreign partners

3.3.1 RMB appreciation will help lower purchasing cost of overseas material and reduce production cost RMB appreciation means the devaluation of the foreign currency.

Companies can use an equal amount of yuan to buy more raw materials from overseas market, and therefore reduce the final cost and hedge the impact of the domestic inflation. Along with the RMB appreciation, the domestic price level rises rapidly for raw materials and labor costs and harms the export competitiveness of enterprises. Companies should seize the opportunity to take advantage of the high currency, increase the purchase of foreign low-cost factors of production, reduce production costs to rise.

3.3.2 Able companies should increase the direct overseas investment

In the 1990s, the sharp appreciation of the yen forced many Japanese enterprises to develop new technologies and new products to improve value-added products and reduce production costs, but the magnitude of the appreciation of the yen was too large to offset the yen's appreciation [4]. To increase the competitiveness, the majority of enterprises adjusted the business strategy and adopted approach of the direct investment. They built local factories, purchased and sold locally and thus maintained the share of exports business. Therefore, Chinese companies should learn from their experiences and set up factories overseas. This is not only to seize the foreign market but also to bypass the barriers and reduce the increasing trade friction.

Suggestions and strategies

4.1 Speed up the product innovation and promote the development of industrial clusters

Most of the sporting goods industry are labor-intensive, low value-added. They are likely to get hit first during market turmoil due to the lack of product innovation and brands. The sporting goods industry cluster development can promote the product specialization, increase the economies of scale, reduce transaction costs, and help share information, technology, brand and sales network channels and thus increase the ability of resisting the risks.

4.2 Adjust the industrial structure and speed up the industrial upgrading

RMB appreciation can reduce the raw material cost and can be used to adjust the product structure and accelerate new product development and research. With increased usage of imported parts and raw materials, companies can further increase their export shares, China's sports goods exports was mainly targeted at the United States, Japan and Hong Kong. RMB appreciation would weaken the competitive advantage of these companies. They are forced to speed up the restructuring and upgrade their products [5] and move from the low value-added processing to high value-added products. During this value chain upgrade, companies can enhance their international competitiveness and reduce the exposure to the risks of price competition.

4.3 Use "going out" strategy to reduce trade friction and avoid trade barriers

After thirty years of development, there emerged a number of listed Chinese sporting goods companies who own their own brands and R & D capabilities. They have the capital, technology and marketing channels and the ability to expand overseas. They should take advantage of the RMB appreciation to invest in foreign markets directly, use local production and local sales to bypass trade barriers and reduce trade friction. On the other hand, they should actively explore new markets and focus on Africa, Eastern Europe, Central Asia and other emerging markets to avoid the adverse trade situation due to over-concentration on developed markets.

4.4 Actively participate in the export credit insurance

Export credit insurance is the insurance policy offered from the Chinese insurance companies and banks to encourage enterprises to export and protect their income stability. Under the circumstance of large fluctuation of RMB, sporting goods export enterprises should participate in these insurance programs, using limited insurance costs to lock down the currency benefit of the coming period and have the insurance company to share the losses caused by appreciation. This will help enterprises to maintain more stable operation.

4.5 Improve the business training and increase the enterprise's risk awareness

Chinese enterprises have been accustomed to a fixed exchange rate and relying on the currency devaluation and low cost to stimulate exports instead of strengthening the management, reducing costs, improving the efficiency to enhance export competitiveness. A considerable number of domestic companies are still not aware of the potential impact and risk of rising exchange rate. Government should reach out and do more research to educate these companies. 5. Conclusion. In summary, RMB appreciation has become unavoidable and the sporting goods export enterprises bear the brunt of its impact. It is not so meaningful to discuss the pros and cons at this moment and it is more important for companies to find coping strategies, such as increasing the purchase of foreign raw materials and other parts, more direct investment in local markets to get around the trade barriers, and upgrading the products and more innovations.

Keywords: virtual performance evaluation; Internet of Things; dynamic alliance performance

Abstract. With the development of modern information and communication technology and network technology, modern enterprises choose to build virtual dynamic alliance to achieve business development goals. There are many uncertain relationships between the participating companies in the virtual dynamic alliance. These companies join together to accomplish a particular goal, but also has their own unique individual needs. Internet of Things is an important part of a new generation of information technology. Things technology is an extension and expansion of the network based on the Internet. Basis for building virtual dynamic alliance is the Internet. The enterprises participating in a virtual dynamic alliance communicate with each other relying on information communication technology. Internet of Things technology provides real-time performance evaluation data to the participating enterprises. This will ensure real-time performance data communication between the dynamic alliance enterprises relatively loose.

Introduction

Dynamic alliance is a virtual dynamic structure, which incorporates many enterprises management realistic goals and expectations of future developments. Dynamic alliance is a common mode of operation and management of the project. Many enterprises will participate in the dynamic alliance in order to complete specific core projects. These participating enterprises of dynamic alliance have their own management entity.

In order to better achieve the specific project objectives, the dynamic alliance need to establish an effective of real-time performance evaluation system. Such evaluations system will be beneficial to each participating enterprise for the real-time regulation and management. If each participating enterprises can achieve real-time performance communication, performance evaluation of dynamic alliance can be achieved on the participating enterprises real-time evaluation. Meanwhile each participating enterprises can also get rectification dynamic alliance performance evaluation system in the first time.

The dependency between the participating companies of dynamic alliance is a dynamic process of change. Performance evaluation system of the dynamic alliance will collect the daily performance effects of the participating enterprises real-time. Virtual combination architecture of dynamic alliance requires a dynamic real-time data communication platform. Things technology can take full satisfy the real-time data communication needs of virtual performance evaluation in dynamic alliance. Things technology can efficiently complete the communication and sharing of data, combined with the actual implementation of the core projects in the dynamic alliance virtual performance evaluation process.

Performance evaluation of the dynamic alliance

Virtual dynamic alliance is an external optimization and integration based on the core competencies of the core business. Alliance's core businesses will focus their own investment and

management attention on their core capabilities. They make other dynamic alliance enterprises to accomplish the non-core capabilities and the ability that they could not master in a short time.

The more common performance evaluation process will use mathematical statistics, operations research principles and specific indicators. In the performance evaluation, the organization will reference to a uniform standard, accordance with certain procedures. Generally, the organization's performance evaluation will rely on quantitative and qualitative comparative analysis method. Within a certain period of operation of each project, the normal performance evaluation process will make an objective, fair and accurate operational efficiency and comprehensive evaluation results of operations for these projects.

Dynamic business alliances is an integrated enterprises combination based on the core needs of the project. The enterprises themselves are individual independent body. All enterprises in their business activities have established a performance evaluation system in line with their own development needs. Each enterprise in a dynamic alliance enterprises need to adapt to other collaborative enterprises according to the actual operation of the core project. These enterprises will continuously adjust their own management process in compatible with the overall performance of dynamic alliance in order to meet the requirements of the overall dynamic alliance performance evaluation system.

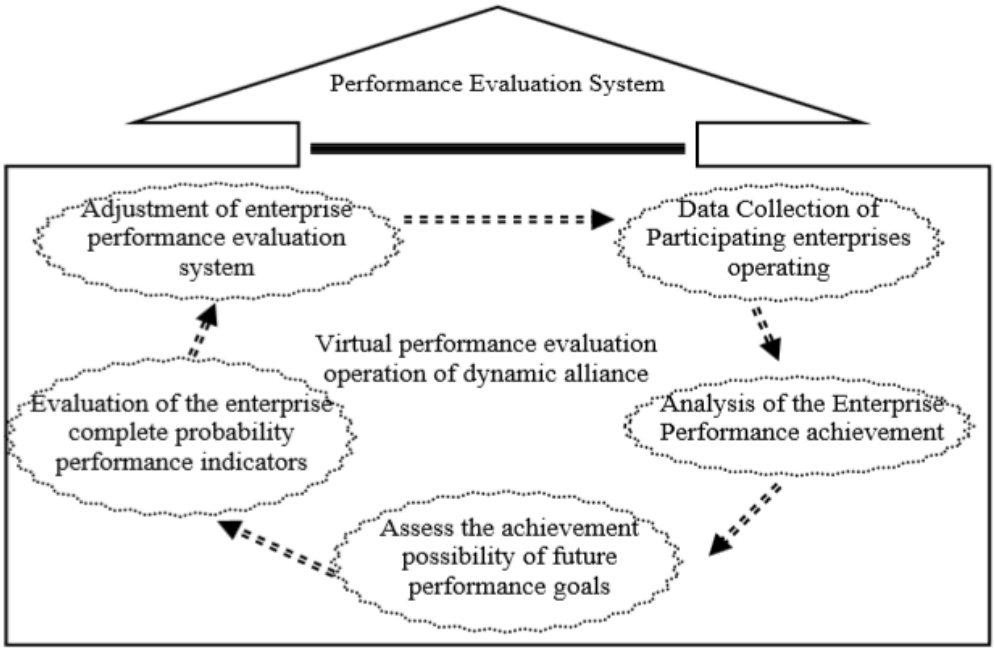

Figure 1. Virtual Performance Evaluation of Dynamic Alliance

Performance evaluation of dynamic alliance is different from the ordinary business of the daily performance evaluation process. Dynamic Alliance of each enterprise will be subject supervision and evaluation of real-time, based on performance evaluation system dynamic alliance. Guided by real-time performance evaluation indicators, the participating enterprises can conduct business management and operations to meet the overall goal of dynamic alliance. Performance evaluation of dynamic alliance will no longer be directly linked to the expected evaluation of specific participants. The foundation of the dynamic alliance is based on the expected return of the core projects. Each participating businesses will organize their own business enterprises in accordance with their understanding of the expected benefits of the project. Therefore, the participating enterprises are possible to adjust their position in the dynamic alliance at any time, even with dynamic alliance relationship, according to the needs of their own survival and development. Performance evaluation of dynamic alliance should always be in the form of a dynamic evaluation system. Such performance evaluation will play a supervisory role for the alliance participating enterprises in the process of realization of dynamic alliance's overall performance goals.

About Internet of Things

Internet of Things is an important part of a new generation of information technology. Internet of Things is a model which is based interconnection, grand Integration and based SaaS operations on cloud computing, etc. Internet of Things will connect the ubiquitous of terminal equipment and facilities, using a variety of wireless or wire line long-distance or short-distance communications network.

Internet of Things technology is widely used in the integration of network resources through intelligent perception, recognition technology and pervasive computing, etc. The clients can already extend and expand the process of information exchange and communication between any goods and goods. Internet of Things is an extension and expansion of the network based on the Internet. Core and foundation of Internet of things is still the application about the Internet.

Internet of Things is an extension of the Internet technology in modern information communication and processing technologies. It will meet the needs of the actual resources sharing between customers at a deeper level and extent of broader. Internet of Things includes all resources on the Internet and the Internet. Internet of Things is compatible with all Internet applications. But at the same time all the elements in Internet of Things have the characteristics of personalization and privatization. So, Internet of Things will be able to provide basic networking platform to ensure the integration of the personalized resources and the common network applications.

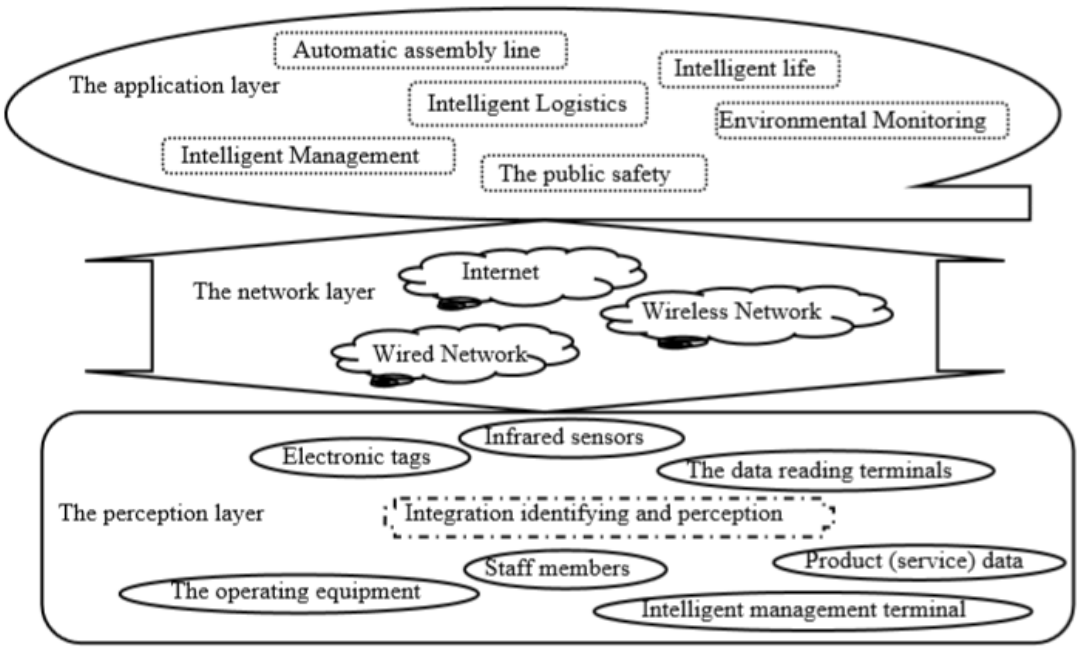

Figure 2. Internet of Things constitution

Internet of Things will provide a real-time open, smooth communication customer communication space as a new the application Internet technology. Internet of Things will be able to ensure timely obtain the relevant information and make the appropriate feedback based on certain criteria. Various services provided by Internet of Things are based on all types resource sharing and instant communication needs between users.

Things technology impact on the dynamic alliance virtual performance evaluation

Basis for the establishment of a dynamic alliance is dynamic random integration purposeful for each of the participating enterprises. In the implementation process of the project, these companies can maintain instant communication and information sharing fully. In order to achieve the common goal, the dynamic alliance will build up a performance evaluation index system focus on the project implementation process.

With operation of dynamic alliance, the virtual performance evaluation index system will conduct performance evaluation in real time for each of the participating enterprises. Virtual Dynamic Alliance is a loose organizational structure. There are no fixed mutual restraint mechanisms within the Alliance between the various participating companies. In order to ensure the efficient implementation of the dynamic alliance project, the participating enterprises need ensure the smooth realization of the overall performance objectives by developing and implementing effective performance evaluation system. The excellent performance evaluation system requires a practical implementation system. The participating companies of dynamic alliance can guarantee real-time communication with each other through the implementation demand of specific projects.

Internet of Things widely used provides an effective support for real time communication and information shared between the companies of dynamic alliance. So each participating companies can play a unique role in the dynamic alliance while ensuring their own development. Performance evaluation system the dynamic alliance requires all participants to ensure timely adjustments in project implementation process. Application of Internet of Things technology can provide maximum support to meet this demand. Internet of Things will play an important role in constituting in the dynamic alliance.

Dynamic Alliance need to ensure that the status of each participating enterprises revolve around the overall objectives of the Alliance. The various enterprises in the loose alliance need maintain close mutual communication to reflect and observe through the actual business indicators. Internet of Things can provide timely the reaction current status of business execution of each participating enterprise data.

Summary

Dynamic Alliance has a strong adaptability and vitality in adapting to the changing needs of the market process. Enterprises involved in the dynamic alliance work efficiently with other participating companies in the process of achieving their own development. Highly efficient collaborative work among the participating companies needs an effective performance evaluation system. Virtual Performance evaluation of dynamic alliance requires keep abreast of the participating company's performance implementation.

Internet of Things technology stands ready to provide communication and information sharing effective protection for various enterprises in organizations operation process of the dynamic alliance. Internet of Things technology will facilitate the effective operation and favorable development of dynamic alliance virtual performance evaluation system.

Keywords: Service innovation; Logistics public information platform; LOGINK

Abstract. By taking the national transport logistics public information platform as the research object, the differences between the logistics public information platform and service enterprises in organizational structure, operational management, information flow, etc., are analyzed in this article. On the basis of four dimensional model of service innovation, three dimensional multi-dynamic model of LOGINK service innovation is proposed. Besides, the connotation and the mechanism of each innovative factor in the model are analyzed.

Introduction

Currently, the research on service innovation targets mainly companies and four dimension model, driver model and other conceptual models of service innovation are studied in China. Regional logistics information platform, the dimension and driving force of service innovation of which are greatly different from those of service enterprise, is one part of the service industry. Because of the less study on service innovation of regional logistics information platform ,the dynamic relational model of service innovation for Regional logistics information platform is analyzed, taking the national transport logistics public information platform (LOGINK) as an example.

Logistics exchange code, logistics information exchange sharing and logistics common software are provided freely for logistics industries in LOGINK platform. LOGINK platform user objects include government regulators, industry associations, logistics providers, logistics demanders and other logistics activity participants.

Four dimension model and basic dynamic model of service innovation

Basic dynamic model of service innovation. Sundbo and Gallouj take a single enterprise as the interface to identify the driving force and divide the driving forces into internal driving force, which includes corporate strategy and management, staff, innovation departments and R&D departments, and external driving force, which contains track and behavior [1].

Guangming Zhang(1998) puts forward a service innovation universally applicable model——four dimensions of service innovation model, which shows that service innovation outside the innovation technology triggers occur more often. What' more, it more involves the following factors, such as changes of service feature itself, sales way, way of "customer – producers", service production process and so on. Generally speaking, service innovation contains the effects of a variety of factors, which are intertwined through a complex process to generate innovation. While four dimensional model uses a structured way to describe, analyze and integrate the multiple factors influencing service innovation[2].

The four dimensions in four dimensional model are respectively referred to new service concept, new customer interface, new service delivery system and technology. Figure 1 shows the relationship of the four dimensions.[1]

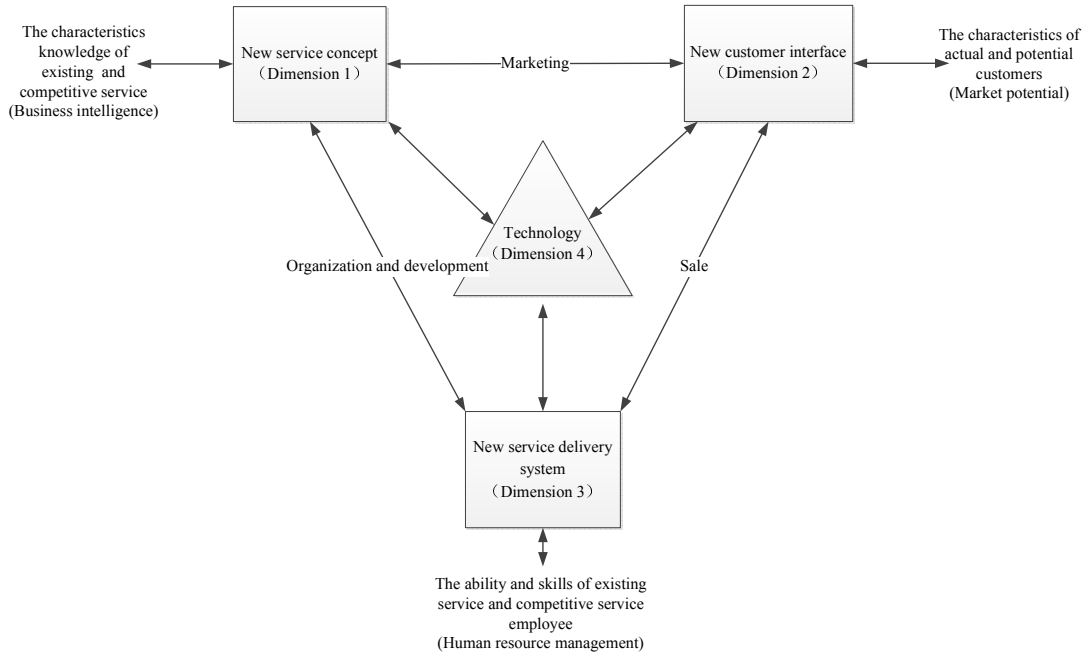

Fig.1 Four dimensions of service innovation model

Three dimensional multi-dynamic model of LOGINK service innovation

The application objects of basic dynamic model of service innovation are service enterprises. However, There are significant differences between service companies and logistics information platform in the organizational structure, operations management, information flow, etc. LOGINK is analyzed as follows.

LOGINK employees includes operation and maintenance personnel and customer service staff of the platform. Operation and maintenance personnel is mainly responsible for the general website and server routine maintenance, less contacting with the users. While customer service staff on the one hand helps the unit of data exchange construction to complete the server deployment and access. On the other hand, the staff completes the recommendation and certification of logistics management software, a certain contacting with the users.

（2）LOGINK strategy, which is determined before the platform development, in order to guide the platform development and construction, but difficult to guide the platform operation is provided by knowledge and technology suppliers. There are no special marketing departments and innovation sectors during LOGINK operations. Hence the platform innovation is more from construction planning and strategy formulation.

（3）LOGINK customer interface for one thing exists between customer service staff and users, for another thing among general website, logistics management software, public application service and users. This requires specialized tools to get information of the actual users and potential users.

（4）The particularity of LOGINK customer interface and organization structure makes the service delivery system and customer interface work together to the users, which affects the user's perception of service products.

Based on the above various factors, considering the difference between the characteristics of logistics information platform service production process and the problem angles which four dimensional model describes, three dimensional multi-dynamic model of service innovation of transportation logistics public information platform is proposed. This model is showed in Figure 2.

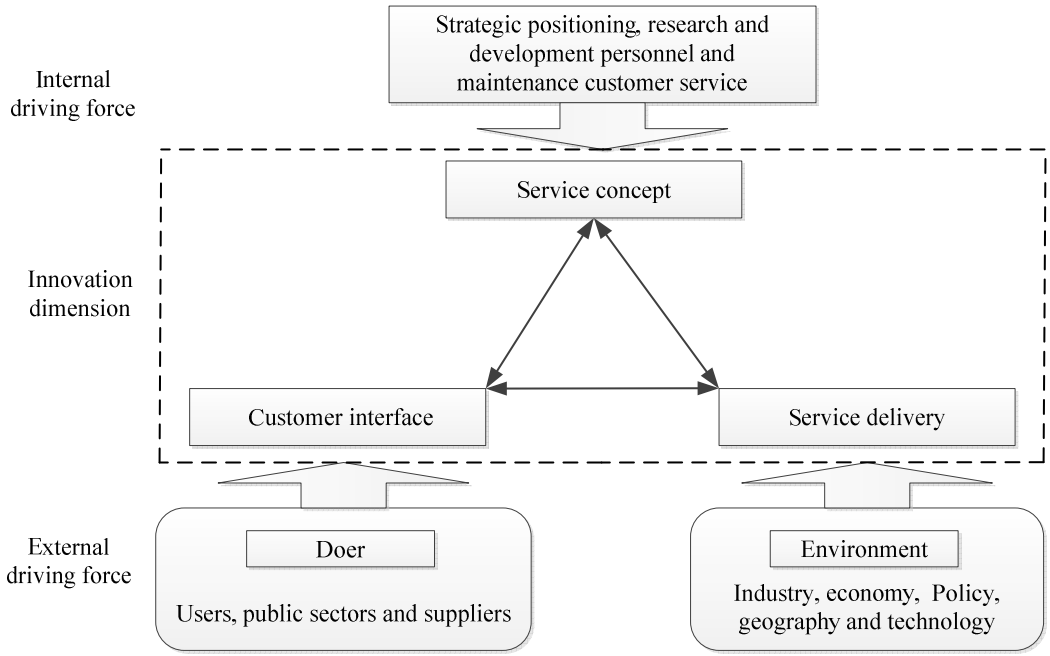

Fig.2 Three dimension multi-dynamic model diagram

Service innovation driving force. Three dimension multi-dynamic model consists of external driving force, internal driving force and innovation dimensions. Among them, the driving force module is characterized by that what forces logistics information platform in reality to drive all kinds of innovations. If a logistics information platform is used as the interface of driving force identification, the driving forces can be divided into internal driving force and external driving force.

For internal driving force of logistics information platform, strategic positioning, research and development personnel and maintenance customer service are included and the strategic positioning is the main internal driving force. The strategic positioning determines the core functions of logistics information platform, customer interface and business model, namely the core service, service delivery method and expanded service supply in the dynamic model of Gronroos expanded service supply. Setting a good strategic positioning provide an excellent innovative and competitive environment， where logistics information platform should make full use of its internal driving force, through the strategic positioning to promote the emergence of innovation.

External driving force of logistics information platform contains doers and environment. Doer is an important external driving force of logistics information platform service innovation, which generally includes users, public sectors and suppliers. The users, which can be a person, a department, an enterprise or even another logistics information platform, create demand for logistics information platform and are also the most important source of innovative ideas in the service package production, service delivery and expanding service supply. For logistics information platform, public sectors are also the important driving force of service innovation, some public sectors are demand service sectors, which use their own needs to drive service innovation of logistics information platform. While some are control departments of logistics information platform, which increase or decrease constraint conditions to cause a variety of innovation. Obviously, Logistics information platform service provider, which refers to technology and knowledge supplier, is also an important driving force of service innovation. The suppliers are an important source of innovation thought and important enabler of innovation activities and have the ability to promote the implementation of service innovation.

Environment is the other external driving force of logistics information platform service innovation, which contains industry environment, economic environment, policy environment, geographical environment and technology environment. Here, the industry environment is divided into logistics industry environment, which comprises logistics industry scale, the logistics industry development speed, the total cost of logistics industry influence factors of logistics industry scale,

logistics industry development speed and total logistics industry cost, and logistics information environment, which includes influence factors of logistics information platform and logistics software. Besides, the economic environment contains GDP, scientific research investment, research and development (R&D) spending and so on. The policy environment mainly refers to the geographical location of logistics information platform service object, for example, whether is located at the border port, and whether there is water transport demand, etc. The technology environment mainly devotes the application maturity of technology related to logistics industry and information technology, for example, whether there is application of new technologies, etc.

Service innovation dimensions. Innovation dimension can be understood as degrees of innovation achieving, including service concept, customer interface, service delivery. The service logistics information platform provides is high invisible, thus the innovation is conceptual. For example, the core functions of the platform and additional functions are part of the innovation of service concept, the core problem of which is that what kind of function products the logistics information platform targets to provide for users. Customer interface refers to what kind of windows the logistics information platform shows the customer. The layouts, beautiful and convenient degrees of general sites, and even the memorability of the domain name are important points of service innovation to producing. Besides, service delivery devotes the mechanism operating which makes the logistics information platform healthy for long-term, including the mechanism how to build and how to operate.

Summary

Regional logistics information platform is one of the important categories of service sector and the service innovation usually occurs in three dimensions of service concept, customer interface, transmission mode. The driving force which impulses the generating of driving service includes two aspects, one is internal driving force, which contains strategic positioning, R & D personnel, customer service maintaining and so on, and the other is external driving force, which contains actors and environment. Users, public sectors and suppliers are involved in actors. And Environment refers to industry environment, policy environment, economic environment, technology environment and geographical environment, etc.

Key words: visual simulation technology; college English

Abstract. With the rapid development of modern information technology, visual simulation technology is widely used popularized in the construction of college English. Therefore, this paper tries to have a further research on visual simulation technology into college English. Results show that the visual simulation is very important to improve students' recognition, understanding of tourism English training courses.

1. Introduction

Visual simulation technology is a new branch based on computer simulation technology, computer graphics, image generation technology and information synthesis technology, display technology. Its aim is to realize the simulation of realistic effect in the real environment through the visual graphics representation, image representation, structure information and visual characteristics. As the key presentation form of Virtual reality (VR for short), visual simulation technology has more perceptual (multi-sensory), immersion, interaction and vision (imagination) and other typical characteristics. At present, the visual simulation technology has been widely used in military drills, city planning, film and television production, simulation, driving simulation, interactive entertainment, virtual tourism scenic spots and historical sites and other fields. Relevant scholars attempt to study different levels, but the research associated with college English is little. In this research, the author tries to explore the application of visual simulation technology in the college English.

2. Research design

Based on visual simulation environment software Vega technical requirements, the school creates simulation practice interactive visual simulation platform combining with Photoshop software technology. Combining scholars like Luo Yu's research results and experience, such as building "human-computer interaction platform to create a visual simulation technology practice job evaluation scenario a" in the integration of training higher vocational tourism English teaching framework (see figure 1)

3. Training class

This part will introduce the procedures of the class training.

3.1 Task assignment

Learn to use the interactive platform through human-computer interaction platform with the visual simulation, training students to use English and improve language communication skills in the 3d imaging business scene matching workplace. For example, when virtual scene of festival activities appears the human-computer interaction platform, students use headphones to hear several groups of slogan to clearly distinguish the most suitable English festival activities propaganda and click action through the mouse and make the right decision

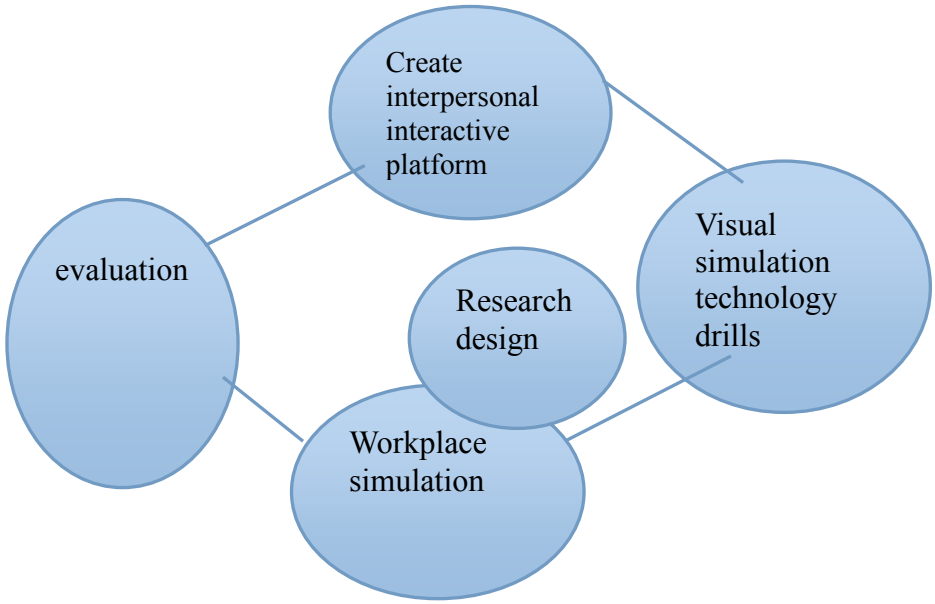

Figure 1 Activities framework

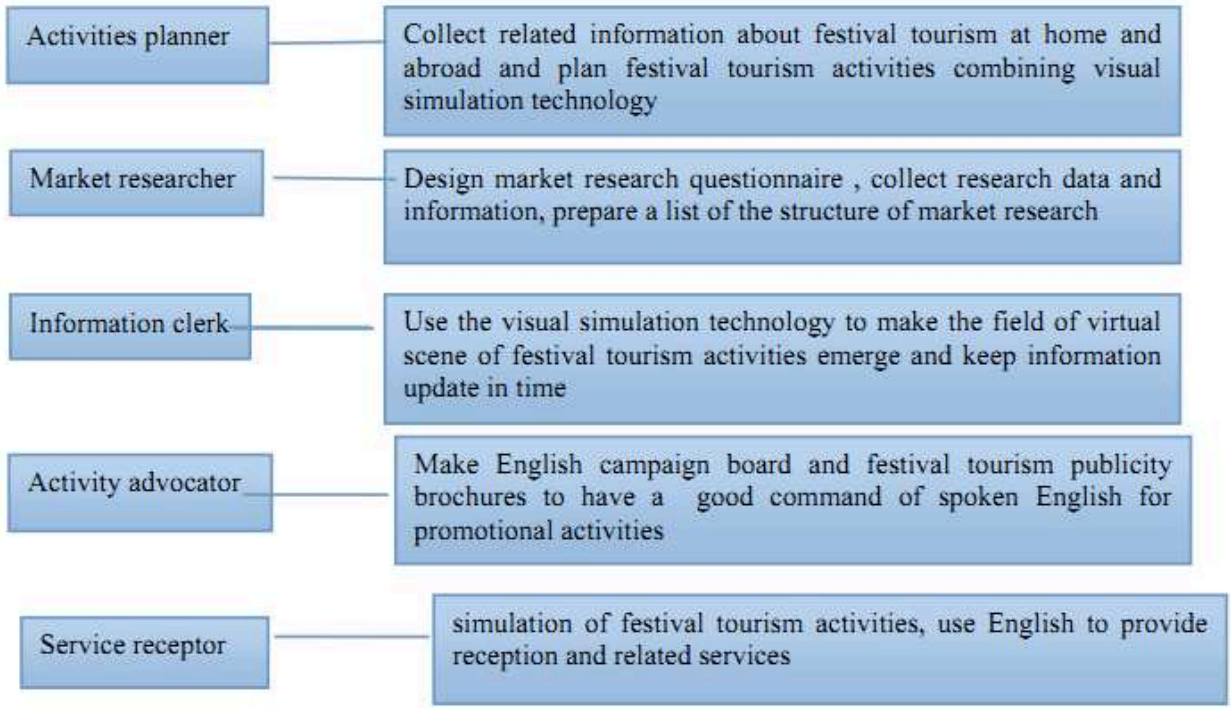

Figure 2 Task assignment

2.2 Form a good workplace communication English expression.

Through standard English demonstration function in human-computer interaction platform , correct the mistakes of English pronunciation, word spelling error and non-standard use habit, gradually form correct and authentic English behavior. For example, some students use Chinese English expression, conduct market research in the early time, ask privacy issues such as gender and age. Then the visual simulation of virtual workplace environment will give the prompt to help correct the language and give correct demonstration.

The role played respectively and the practice According to three dimension visual simulation of festival tourism planning and publicity virtual work scene, the students play a variety of different

roles and receive training, and do different jobs of typical tasks (see figure 2), to motivate students' learning initiative, develop students' ability of creative thinking and practical application.

4. Evaluation of learning results

Teachers give real-time monitoring to students in the whole training, give instant solutions to the problems of students, and meanwhile give a comprehensive assessment and evaluation of typical tasks from different levels.

Assessment program	Content
Human-computer interaction platform control ability	Application ability of visual simulation technology
	Graphics auxiliary processing skills
	Three dimensional simulation and human-computer docking ability of virtual workplace situations
Comprehensive use of English	Accuracy of English pronunciation
	English listening
	Simulating English dialogue
	English normative exhibition planning, and writing accuracy
	The match between workplace and working language
The implementing ability of tasks	The accuracy of completing the task
	Timeliness of completing the task
	The flexibility of coping with emergency
	Cater for the standard of the field
Professional quality	Awareness of work role
	Responsibility
	Awareness of team work
	Communication ability

Summary

The application of the visual simulation technology into the classroom teaching of college English, on the one hand, gives the workplace through the three dimensional simulation where the student can practice and have a clear cognition of the concrete work, lays a good foundation for the future career. On the other hand, it provides the human-computer interaction platform where students can have access to information and create a more efficient, convenient and information sharing of the English language learning atmosphere, stimulate the students' interest in learning tourism English and passion. In fact, based on the visual simulation research, the research on the the modern technology has been broaden and more importantly, students work by simulating the real scene, enhance its typical tasks to specific jobs and cognition and improve the professional quality of personal and professional dedication through it. This research only focuses on one aspect, in the future study more aspects can be studied.

In the college English class, it is evident that visual simulation technology is useful so that it can an aid to English teaching. It not only stimulates the interest of English learning but also improve the efficiency of English.

Keywords: modern Information Technology, competitive sports, modern Science

Abstract. Science and technology is the first productive force. The development of the society and the rapid development of science and technology have brought great push to the economy and social development. By means of computer and the Internet for information transmission, high and new technology and the emergence of a multidisciplinary scientific research such as modern science and technology become our milestones of the contemporary social modernization. Current new revolution of science and technology will further accelerate the process of modernization of competitive sports and have great influence on the development of sports skills. Modernization of competitive sports has become the inexorable historical trend. Therefore, modern science and technology plays a very important role in sports.

1. A general introduction of Modern Information Technology.

Chart 1 we know that information technology is the study of information acquisition, transmission and processing technology, which consists of the computer technology, communication technology, the combination of microelectronics technology, sometimes called "modern information technology". That is, information technology is the use of computers for information processing, the use of modern electronic communication technology in information collection, storage, processing, utilization and related products manufacturing, technology development and new subject of information service. Information technology mainly includes the sensor technology, communication technology, computer technology, micrographics etc.

Task of sensing technology is to extend the function of sensory organs to collect information. Communication technology's mission is to extend the human nervous system function of passing information. The development speed communication technology is amazing. Computer technology to extend the human's organ function of dealing with information and decision-making. Computer technology and modern communication technology together constitute the core content of the information technology. Microfilm technology to extend the function of the memory organs to store information.

2.Modern Information Technology and sports.

Sports, is a integrated discipline refers to natural, social and psychological and technology. It produces with the production of the society, also develops with the development of society. In the transformation from traditional sports to modern sports, its connotation and structure have been changed. As the trend of sports socialization, modernization and globalization, information technology plays a more and more magical effect in competitive sports.

Chart 1 we see sports needs information technology, and in turn, information technology also needs sports. The development of sports and information technology together has become not only an important part of sports development, but also the objective request of modernization of sports and the inevitable trend in the development of sports.

The 21st century is the century full of information and technology. In Chart 1, Information as a subject is known as the four important subjects, including life sciences, materials science, information science and environmental science. The development of competitive sports and the improvement of athletes performance to a large extent depend on the information technology.

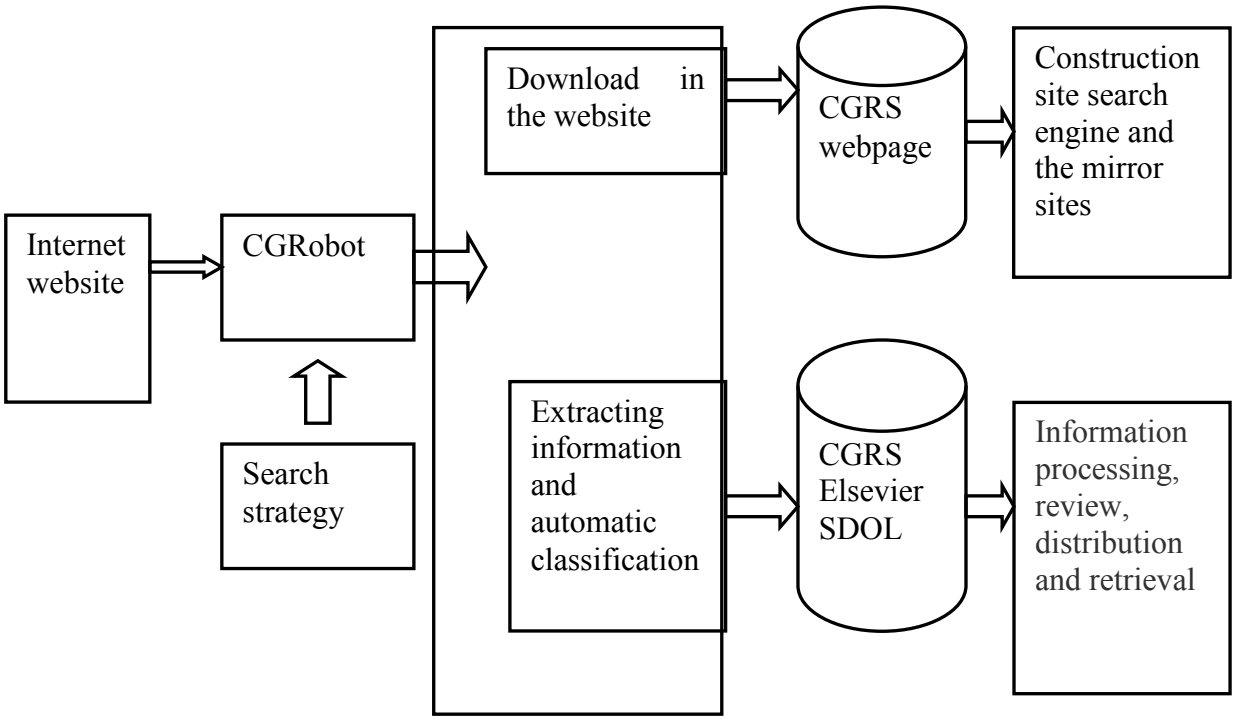

Chart 1: Structure of internet information collection

3.The necessity of information technology in the research of competitive sports.

With the development of competitive sports, the sports performance has been more and more close to the limit of human physical, so creating new records bacomes more and more difficult for human beings. In order to creat new records and good scores close to limited range, countries around the world, especially developed countries, spare no effort to developf information technology and applly in sports, which becomes one of the focuses on the information technology and sports scientific research. Application of information technology provides a reliable basis for improving competitive sports and training method.

Currently, application of information technology in competitive sports mainly includes: to diagnose the sports training, which provides a new way and new method for scientific diagnosis such as: using infrared light spot to measure the position of human space; using two-dimensional human body center plate machine to test the stability of the shooter and to establish data quick feedback system of the sports technical characteristics.; using high-speed photography, camera machine, quantitative analytical technique movement, electronic telemetry technology developed by heart rate meter, remote sensing telemetering heart muscle, to measure the heart rate of all the athletes in the movement and scientifically diagnose the athletes' functional status.

4.Application of information technology in competitive sports.

Modern athletic sports gradually developed from natural and simple activities to the degree of standardization and normalization by using modern information technology. It is based on scientification and standardization of sports; it relys on the development of modern information technology. It plays the decisive role in raising the level of competitive sports.

4.1 Application of information technology in the diagnosis.

Computer is widely used in technical analysis of athletic sports, as human eyes can nethier distinguish whether the player swivels shoulders more or less nor determine that some athletes' foot landing forward 1 cm , but the internet can measure these diny differences. Through the use of advanced video technology, multidimensional camera, photography and parsing technology we can diagnose the defects of techniques, and compare with the correct and advanced technology gap to provide the means and key to improving technology.

From chart 2 we know that computer has the characteristic of fast and efficient feedback, making use of this characteristic can greatly improve the training effect. Because the computer has the function of storing information, and can store all kinds of training and function index data for the comparative analysis later. And using computer to know your opponent's skill and tactics, feedback to their coaches and athletes in time in order to adopt targeted training methods, thereby improving their performance.

Est.			

Chart 2: Capacity analysis of the score statistics from 2001 to 2003

A means World Cricket Championship pro; B means World Cup; C means World Ranking; D means other international contests.

4.2 Application of information technology in learning new skills and doping control.

The modern athletic sports competition is not only the competition of physical strength and skill, but also the competition of high-tech information intelligence. Shoot the process of aopeitio and make it digital to use computer to transform into line diagram, to analyze every movement, to identify every action, speed, strength and acquisition and other important factors of the body.

Before the 60s, each country focused on the research of all kinds of cholesterol drugs. Under the same conditions, whose drug research level is high, who can get the more gold medals. Untill the early 90 s, the number of illicit drugs limited by the world anti-doping commission has been more than 120. People are looking forward to the development of information science, biology, genetic engineering and molecular biology and other high-tech development to make greater contributions to the development of competitive sports for the 21st century.

Summary

Modern science and technology plays an important role in sports, the emergence and development of a series of sports are important embodient. The process of sports scientification promotes the reform of sports training system and management system. Experts have undertake training task load and administrative tasks. The traditional experience type of training system and

management system have been replaced by scientific training system and management system. The application of computer, electronics, laser, space and other modern technology is another important symbol of modernization of competitive sports.The constantly emerging of new records and superior performance in the field are connected with the development of science and technology.

Keywords: project driven, asp.net, teaching reform program

Abstract. With the popularization and promotion of the Internet, ASP.NET has gradually become the mainstream of development platform for WEB application. At present, most colleges and universities have opened the door for students majoring in computer courses. Because of the complex of ASP.Net teaching and the teaching target key requirement to cultivate the students' ability of practice, the traditional mode is not applicable to the teaching of Theory of teaching. So, this article made based on the project - driven ASP.Net Teaching. By teachers in selecting suitable project topics, the teacher according to the project needs to explain the knowledge of ASP.NET and ultimately by the students to complete the design and development of the entire project in teaching. Practice has proved that the project-based driving teaching method for students' active learning teaching content and improve students' ability to analyze and solve problems.

Introduction

With the popularization and promotion of Internet, Web programming and Web applications has been an unprecedented development. WEB-based programming has become one of information technicians that must master and the social demand for Web application developers is growing. Current mainstream WEB-based programming languages-among ASP, PHP, ASP.NET and JSP, ASP.NET is for next generation enterprise network computing Web platform, Microsoft.Net is an important part of the strategy, in which new technical architecture will make programming easier for everyone, based on this, an increasing number of colleges of science and engineering to open a course of ASP.NET as a computer science course. And they are in a very important position in the teaching plan.

As an integrated high professional class, prior to student learning ASP.NET, generally fragmented learning principles and application of Internet technology, data structures and database courses, learning through ASP.NET and use theoretical knowledge in practice, a process that I learned, emphasis is on action, so the course is practical. If we still use a single, traditional teachers teaching, students' practice teaching mode, cannot effectively improve students' practical ability, also fail to cultivate the students' ability to independently develop a small and medium sized Web project. Exploration team went more than two years of research and teaching, teaching teams set up a WEB-based program development, develop a practical teaching plan and an effective teaching method.

Set up a team, pre-ordered courses teaching

ASP.NET programming knowledge involved much, page layout of the HTML markup language, classes and objects, database operations, XML files and JavaScript scripting language to use. Due to limited class and the difficult of course settings, and cannot arrange the content of lessons. So organization has WEB program development of practice of teacher composed teaching team, again by members of teams, Division completed static page of produced, C# programming, database, XML language and JAVA program design. Finally, ASP.NET, integrating all knowledge, in the design and development of a student familiar with the project, such a teaching plan, through a semester learning ASP.NET, teaching is notable.

Based on project-driven curriculum teaching

Students learn a computer course, whose main aim is not just to learn some basic information on this subject and, more importantly, is to acquire the knowledge and flexibility to use. In other words, students learn the basic concepts and key technical points, to can learn to apply his knowledge to practical application of the skills. For computer science students, inspired by using a variety of modes, independent learning, strengthening practical training and foster innovation, build up the team spirit is very important. Past, we just according to this and textbooks of order to teach ASP.NET knowledge points, to knows existing of about ASP.NET of textbook, each chapter of knowledge points is not coherent of, After students complete, run into practical problems, still won't work, so learn active enough. There are some students began to study seriously, but with the subjective teaching, many students have given up on ASP.NET learning initiatives, teaching was not satisfactory. To end this, we use the method that based on teaching practice, the development of practice and project-driven teaching method is used in the long term. It is the interaction between teaching and learning mode, the basic idea is: through the whole teaching process to a complete software development project from beginning to end, to build the project as a clue to arrange the teaching steps, the teaching process is driven by the project's tasks. Students in the learning process for a complete project, the whole process of analysis, design and implementation, which combine theoretical and practical education in the classroom teaching organic combination.

In project-driven teaching, the students under the teacher's guidance, specialized theoretical learning, while actual project development. Needs of teachers according to the project design and teaching expertise, which is a combination of theory and knowledge into skills teaching method and fully mobilize the students' interest in learning. It can encourage students to collaborate on the project for the purpose so that students in active and independent learning environment can mutual learning and practice in the learning environment. Students during the teaching process will no longer be a passive recipient, but rather active participants, such openness, innovation of educational thoughts and patterns conducive to overcoming the disadvantages of teaching pattern in the past, more conducive to students' level in the development of the computer information management system to improve.

1) Program selection and grouping

Based on project-driven teaching methods, the key issue is to select an appropriate project and select a project should have the following characteristics:

(1) Projects should have a certain level of representativeness, while a project may not have all the features of a class.

(2) Projects should have a certain degree of practicality. Project comes from actual job requirements, selection and actual needs of the project as much as possible. Combining with scientific research tasks, technological development, needs of the construction and practical application of selection is required.

(3) The size of the project you should moderate. Big-scale projects are difficult to complete a course contact hours and students are elusive. Small-scale projects are difficult to cover the major points and lacks integrity and challenging.

(4) Instructor for the selected projects should be very familiar with and preferably teacher personal development projects.

(5) Project echo students living close to enhance the students' interest on the one hand, but more importantly is to facilitate students' understanding and acceptance so that students focus on the technical aspects of the project, and can't waste too much time on the investigation.

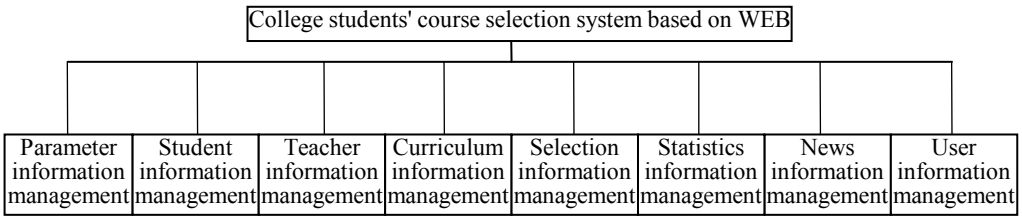

Fig. 1 College students' course selection system functional block diagram

Based on the above factors, in our teaching practice of ASP.NET, we use "University students' course selection system based on B/S mode" as a case study. Main modules of the system as shown in Fig. 1. After you decide the project, focused teaching classmates, based on four people in a group, each group to identify a group, each group in the Division of personnel, then the leader, according to the software engineering mind to organize and coordinate. Ask each group at the end of the term, it submit a software design and software user manual assessment of each student as semester basis.

2) According to the required, adequate, strengthening the relevance and applicability of principle of reforming teaching contents.

If single, sequentially teach that content also makes students feel teaching is not practical, nor can stimulate students ' learning activeness. To standardize the teaching content and our ability to course objectives the course modules are divided, projects combined with select, refines each unit of competency requirements according to the required, adequate, strengthening the relevance and applicability of principle of reforming teaching contents, this section requires students to learn by themselves accomplish. Specific teaching contents as shown in table 1.

Table 1 ASP.NET academic content

Chapter	Project content	Practice of project
Basic controls	validation controls, Html controls, navigation controls.	1 Data entry page; 2 Shows output page; 3 Member registration; 4Information.
ASP.NET programming	ASP.NET built-in object and file processing.	1 page access control; 2 site visit statistics.
Database operations	ADO.NET, basic database operations, and controls such as Gridview.	1 student information management; 2 course registration information management; 3 various access database operations.
Integrated project	ASP.NET application design.	College students' course selection system.

3) Based on the implementation of project-driven teaching

In the teaching of teaching content, take the spiral model is similar to software engineering, not once finished the entire contents of a cell, but according to needs of the project, take the spiral strategy, along with a project to use the knowledge gradually increased , naturally joined gradual learning content. This is the "project-driven" strategy.

User information management, information management and student three modules based course management throughout the entire process of teaching. Through the project down into a typical case, using succinctly and training, teachers operate, then students practice understanding, in order to achieve the main line tasks. Deepen students' understanding of the importance of professional courses, specific teaching process is shown in Fig. 2. Through each lesson task to achieve, students completed the project tasks, but also mastered the new knowledge in ASP.NET. Teachers completed the task of teaching, but also allow students to practice and theory of organic integration, but also improve the students' independent analysis of issues and problem-solving skills.

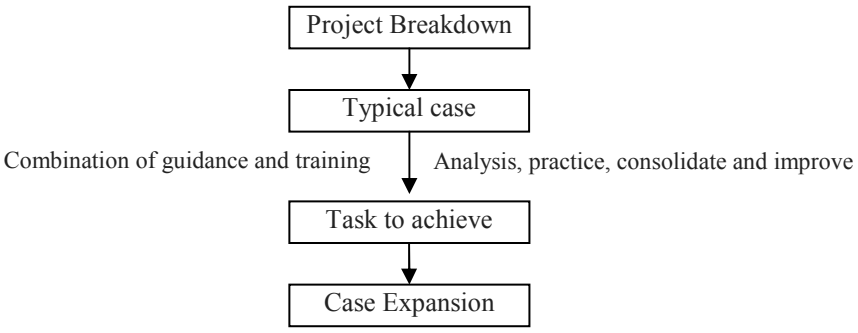

Fig. 2 Project-driven teaching processes

4) Strengthen secondary education

Since the reduction of teaching content, much content requires students to complete self-study after school. To this end we produced a dynamic Web Design Course Website, including multimedia courseware, curricula, teaching materials, online solutions, online testing and instructional video. Excellent use of network resources and guidance to help students after school to learn, but also saves time for the students to find information when self-learning, but also to break through the restrictions of time and space, in a timely manner to solve problems by answering online learning experience, and ultimately train the students independent problem-solving skills to analyze problems. Also contribute to the ultimate realization of the project, so as to complete the task of teaching ASP.NET.

5) Reform the examination pattern, the transition from knowledge assessment for capacity assessment

Traditional "paper-based assessment" approach has not achieved the "test and promote learning," the purpose, basic does not reflect the student's skill level and ability. Therefore, in the evaluation, to achieve diversification and diversification evaluation evaluation topics. Developed a comprehensive evaluation of teaching rated quantization table based on ASP.NET projects, from the overall layout of the site before and after the station management, the learning process, analyze problems and problem-solving skills, active learning and teamwork skills, etc.

6) Teaching Achievement

More than two years, we have adopted the project approach, received remarkable results. Whether the student exams pass rate, or vocational skills certification and graduation rates by more than the proportion of well-designed, has a markedly improved. Of particular importance is due to the students' practical software development capability has been significantly improved, greatly enhancing their employability and competitiveness

Conclusion

ASP.NET-based project-driven teaching computer courses in a strong practical teaching, has incomparable advantages. It enables students to grasp the essence of the mastery of a course at the same time, strengthen the student's computer application software development capabilities, improve their computer software engineering principles to the development of the project analysis, architecture, design, management, documentation, such as the ability to write, to students after graduating in computer technology continues to self-development has laid a good foundation, but also train the students working in cooperation and teamwork spirit.

The rapid development of computer technology and applications, we must promote the reform of the traditional mode of teaching computer courses, constantly updated teaching concept, teaching content, teaching methods and teaching methods. Based on project-driven approach, as we explore in the teaching reform, and achieved some results, we will summarize the experience and lessons learned, the project will be extended to other software development pedagogy teaching practice.

Application Development of Student Score Analysis System for Secondary School Based on Standard Score

Wendong Zhao [1, a], Youdong Zhang [1, b]

[1] Huaiyin Institute of Technology, china
[a] zwd_139@163.com, [b] zyd@163.com

Keywords: Standard score, Secondary school, Score analysis system, MVC

Abstract. They rarely involve deep-seated score analysis in the existing teaching management software, Therefore, we can not evaluate science teaching, Based on this, This article uses the Struts framework and Hibernate framework to design Student Performance Analysis System based on MVC pattern, it Proposed optimization algorithm based on standard score, We can achieve student achievement statistics and analysis with it, This algorithm can better reflects relative position that the individual is in groups, and has a certain scientific. Experimental results show that the system has a good safety and openness, and provides support information for academic departments to promote better teaching work, and finally improve the quality of teaching.

Introduction

With the development of computer technology and Engineering construction that all schools links Internet, the important task of school principals is that achieve educational and teaching quality information management. At present, not only do we want to achieve paperless management computer in the research of score Analysis System, and development a new Student Performance Analysis System Under the existing conditions based on openness and real-time of network. At the same time this system improves the management level, and Document student score, reporting and statistical analysis, assurance student achievement information can be quickly and accurately communicated to students and parents. We carefully study and analysis of existing performance analysis system based on previous research, we adopt standard score as the mathematical model, design and implement analysis and management system of student score using Struts framework and Hibernate framework based on browse/ server mode and J2EE platform, Solve problems of using JDBC technology connection to the database under struts framework model, high coupling between layers and difficult to maintain.

Struts and Hibernate

1) Struts

Struts framework is an open source project of the Apache Software Foundation organized, it provides the underlying support for the development of MVC system [1]. The Core of Struts is a MVC-style controller; source can not contain business processes by using the configuration files of struts controller, this makes maintenance and flexibility greatly strengthened. Although there is no requirement in view, but it offers a lot of classes for developers to use, but struts merely provides an action Class in the model section, let this class to implement all of the back-end business, so Struts support for model section is also lacking.

2) Hibernate

Hibernate is a persistence layer development framework by using ORM mechanism, It is a bridge between Java applications and relational databases, and is responsible for mapping between Java objects and relational databases. It encapsulates operations of JDBC access database that is an independent object persistence framework; It provides API for database access based on OOP to upper class [2]. Programmers can avoid manually write method of access to the data persistence layer; they only need to focus on the development of business logic. Hibernate simplifies the development of difficulty, accelerate the development of the project. However, Hibernate provides only partial support for the model, if we only use the Hibernate framework to develop applications;

System can only be improved in the business model section, logic processing, process control, and views of the system have not been effectively separated, so coupling of the system is not too high, and it is not easy in the latter part of system maintenance.

3) Web application development based on struts and hibernate

We compare the advantages and deficiency of struts and hibernate, if we develop the project by using Struts and Hibernate, By Struts technology to reduce the coupling between the layers of MVC, reduce development effort of the business model by using Hibernate framework, it is a fast and effective solution for Web applications, you can refer the article [3] about their application methods.

The Analysis algorithm of scores based on standard score

In recent years, we assess student test scores with hundred mark system, if a student scores less than 60 points, and then he is a failure in this course. This method is unscientific, it does not accurately reflect the true student learning, because of the difficulty, number and focus of each exam questions are likely to be different, so, it is not science reflect actual student learning situation by using with absolutely scores. So how so you solve this problem? We propose a method to measure student achievement based on standard score [4].

When the computer standard scores, through calculating the value of one score minus the Average of all student scores by using formula (1), then calculated the value of the expression, the value divided by standard deviation, it can better reflects relative position that the individual is in groups.

$$score_i = \frac{x_i - E(x)}{\delta(x)} \quad (1)$$

In the formula (1), $score_i$ represents standard scores for a student, x_i is the original score, $E(x)$ is the average of all student scores, $\delta(x)$ is standard deviation of the original group scores. This evaluation system by calculating standard score certainly has some scientific, but the calculation of standard scores are still relatively complex, we also designed a special optimization algorithms.

The design of Student score Analysis System for secondary school

Through the early research and Qingjiang secondary design requirements, we design Analysis System of Student score for secondary school shown in Fig. 1. The system set up administrators, teachers and students of different types of users. Teachers can input student achievement into system within a specified time, and analysis about class scores, etc. Students can browse the results at any time and place. Administrators can base on the analysis results to adjust teaching methods and teaching ideas.

Administrators are principally engaged in the management of academic information, them main function is to statistics and analysis student scores. Academic Information management is composed of several modules, but the method of each module are similar, in order to facilitate the description of the methods and means of the module, combined with the pre-design requirements, we main explanation class management module, design a timing diagram of class information management In the Senate subsystem shown in Fig. 2.

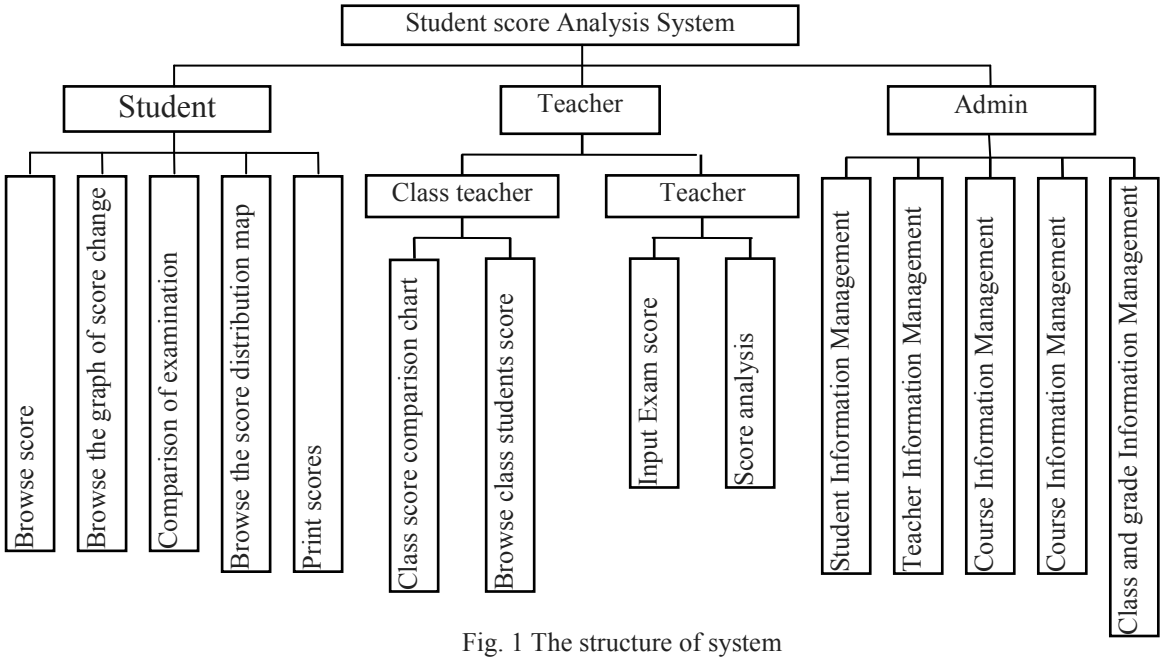

Fig. 1 The structure of system

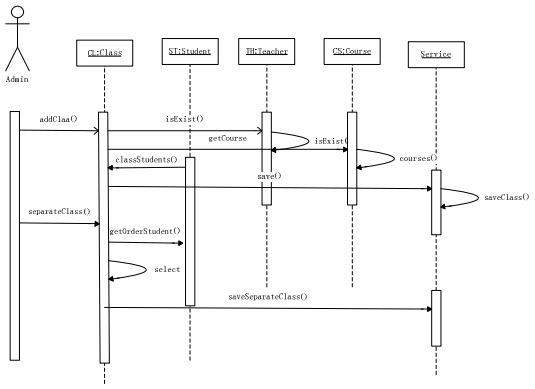

Fig. 2 Timing diagram about class

We can see that management class information is primarily to add new classes, modify class information, Delete class information, show class information and re-division classes according to test scores, for this reason we can abstract the relationship between various types of educational subsystems, shown in Fig. 3.

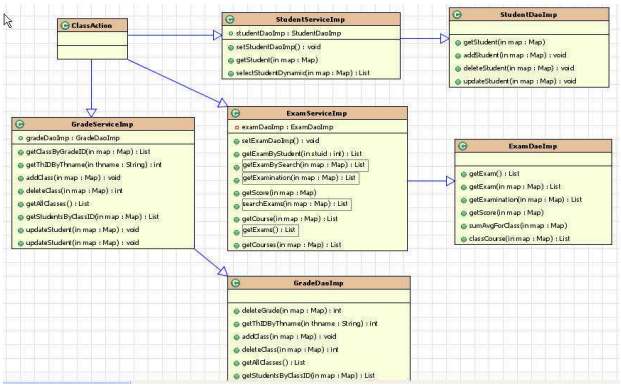

Fig. 3 The class diagram of class

The development of Student score Analysis System for secondary school

When we develop system, design Patterns in strict accordance with the MVC, first adopt JSP to achieve the display of the page, Achieve pages and data steering control by using Struts, Data processing and business logic to be achieved by the corresponding Java Bean, and access the database operations to be done Ibatise, Student score sorted graph is shown in Fig. 4.

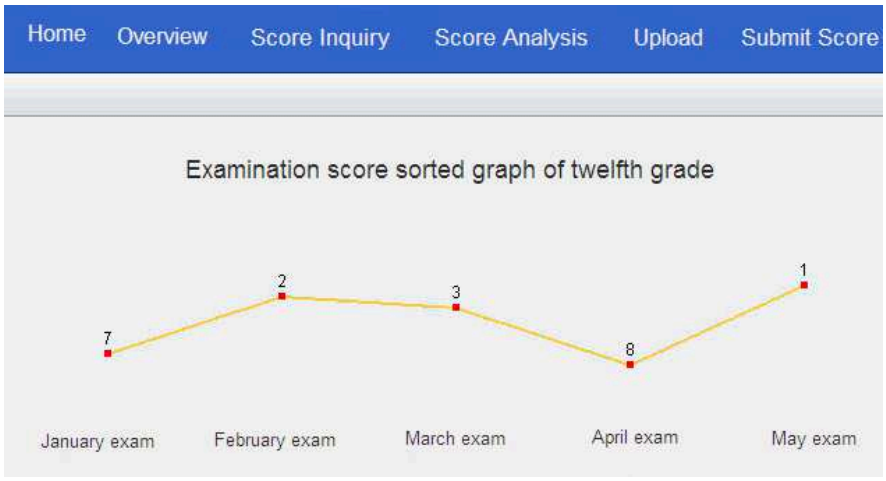

Fig. 4 Examination score sorted graph of grade

Conclusion

This article uses the Struts framework and Hibernate framework to design Student Performance Analysis System based on MVC pattern, after a period of application of the feedback, the results show that the system has good security and openness, the optimization algorithm based on standard score can better reflects relative position that the individual is in groups, and has a certain scientific, and provides support information for academic departments to promote better teaching work, and finally improve the quality of teaching.

Research of Current Situation and Risk of Bitcoin

Yiqing Lu[a]

School of Information Management, Beijing Information Science and Technology University, Beijing, 100192, China

[a]email: luyiqing@126.com

Keywords: Bitcoin; Peer-to-peer; Electronic currency; Digital money; Virtual currency

Abstract. Bitcoin is a pure electronic money based on cryptographic proof instead of trust. The principle of Bitcoin can allow any two willing parties to transact directly with each other without the need for a trusted third party. Bitcoin can represent a totally new anarchy virtual currency and an innovation of digital currency. But its development also needs to face to the security of national policy risk, technology risk and trading risks.

Introduction

Bitcoin is a peer-to-peer payment system introduced as open source software in 2009, proposed by Satoshi Nakamoto[1]. The digital currency created and used in the system is alternatively referred to as a virtual currency, electronic money, or acryptocurrency because cryptography is used to control its creation and transfer. Conventionally, the capitalized word "Bitcoin" refers to the technology and network, whereas lowercase "bitcoin" refers to the digital currency. The Bitcoin system is not controlled by a single entity, like a central, and this has led the US Treasury to call bitcoin a decentralized currency.

The Principle of Bitcoin

Bitcoins are created by a process called mining, in which computer network participants, i.e. users who provide their computing power, verify and record payments into a public ledger in exchange for transaction fees and newly minted bitcoins. Users send and receive bitcoins using wallet software on a personal computer, mobile device, or a web application. Bitcoins can be obtained by mining or in exchange for products, services, or other currencies.

An electronic coin is defined as a chain of digital signatures, as shown in figure 1. Each owner transfers the coin to the next by digitally signing a hash of the previous transaction and the public key of the next owner and adding these to the end of the coin. A payee can verify the signatures to verify the chain of ownership[2].

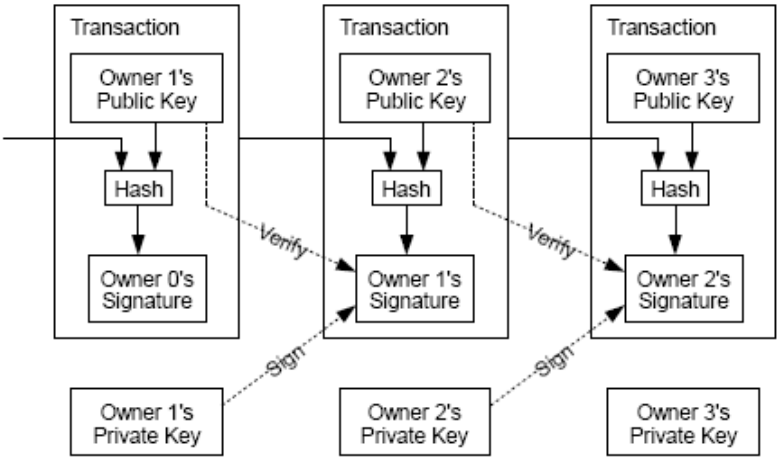

Figure1. Transactions of electronic coin

In the process, to the recipient's inspection，a common solution is to introduce a trusted central authority, or mint, that checks every transaction for double spending. After each transaction, the coin must be returned to the mint to issue a new coin, and only coins issued directly from the mint are trusted not to be double-spent. Bitcoin introduces a timestamp server. A timestamp server works by taking a hash of a block of items to be timestamped and widely publishing the hash, such as in a newspaper or Usenet post, as shown in figure 2[2].

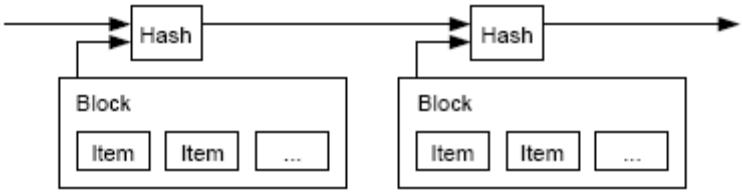

Figure2. A timestamp server

The proof-of-work involves scanning for a value that when hashed, such as with SHA-256, the hash begins with a number of zero bits. The average work required is exponential in the number of zero bits required and can be verified by executing a single hash.

For the timestamp network, the proof-of-work is implemented by incrementing a nonce in the block until a value is found that gives the block's hash the required zero bits, which is shown in figure 3. Once the CPU effort has been expended to make it satisfy the proof-of-work, the block cannot be changed without redoing the work. As later blocks are chained after it, the work to change the block would include redoing all the blocks after it[2,3].

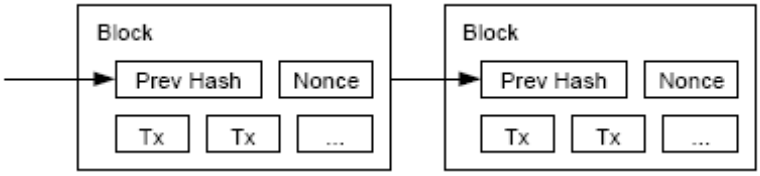

Figure3. The proof-of-work

Therefore, the nature of the Bitcoin can be as a pile of the special solution generated by the complex algorithm. Special solution is refers to the system of equations which can be an infinite number of (in fact, the currency is limited) solution in a group. And every special solution can solve equation and is the only one. Mining process is through a large amount of calculation to seek solutions of the equations. The equation is only 21 million special solutions by design. So the upper limit of bitcoin is 21 million.

The Bitcoin algorithm can ensure all mining and everyone store the results obtained with a mining - Bitcoin trading records. Their manufacture fake doesn't count as a result; still have to must be cut in the recognition of others. Such a design as a result, a person can't forge their wealth, and his wealth will be cut in all people to prove, not easily be deprived.

Bitcoin network has fault-tolerant mechanism. It can ensure even have the deceiver (false information has been released) and troublemakers (has refused to acknowledge others' trade) also won't affect the whole network operation[2, 4].

The Development Status of the Bitcoin

Bitcoin was first mentioned in a 2008 paper published under the name Satoshi Nakamoto. In early 2009, the first open source client (or wallet software), called Bitcoin-Qt, was released and the first bitcoins were issued. In 2009, a feature in the Bitcoin-Qt software was exploited and large numbers of bitcoins were created. This was due, in large part, because Bitcoin-Qt was the only software that facilitated bitcoin transactions and mining. This feature was later removed because specialized mining software turned out to be more efficient. Since then, the bitcoin open-source software has been maintained and enhanced by a group of core developers and other contributors.

By May 2011, interest in Bitcoin was growing as were concerns. The price of bitcoins has fluctuated wildly since its inception, going through various cycles of appreciation and depreciation, which have been referred to by some as bubbles and busts. In 2011, the value of one bitcoin rapidly rose from about US$0.30 to US$32 before returning to US$2. In the latter half of 2012 and during the 2012-2013 Cypriot Financial Crisis, the bitcoin price began to rise, reaching a peak of US$266 on 10 April 2013, before crashing to around US$50.

In March 2013, a technical glitch caused a fork in the block chain, with one half of the network adding blocks to one version of the chain and the other half adding to another. For six hours two Bitcoin networks operated at the same time, each with its own version of the transaction history. The core developers called for a temporary halt to transactions, sparking a sharp sell-off. Normality was restored only when the majority of the network downgraded to version 0.7 of the Bitcoin software from the flawed version 0.8.

Mainstream services began accepting bitcoins as a form of payment as well as certain non-profit or advocacy groups such as the Electronic Frontier Foundation. The first law enforcement events occurred in May 2013: Assets belonging to the Mt. Gox exchange were seized by Department of Homeland Security and the Silk Road drug market website was shut down by the FBI.

In October 2013, Chinese internet giant Baidu had allowed clients of website security services to pay with bitcoins. During November 2013, the China-based bitcoin exchange BTC China overtook the Japan-based Mt. Gox and the Europe-based Bitstamp to become the largest bitcoin trading exchange by trade volume. On 19 November 2013, the value of a bitcoin on the Mt. Gox exchange soared to a peak of US$900 after a United States Senate committee hearing was told that virtual currencies were a legitimate financial service. On the same day, one bitcoin traded for over RMB¥6780 (US$1100) in China. On 5 December 2013, the People's Bank of China prohibited Chinese financial institutions from using bitcoins. After the announcement, the value of bitcoins dropped and Baidu no longer accepted bitcoins for certain services. Buying real-world goods with any virtual currency had been illegal in China since at least 2009.

The first bitcoin ATM was installed in October 2013 in Vancouver, British Columbia, Canada.

With roughly 12 million existing bitcoins as of November 2013, the new price increased the market cap for Bitcoin to at least US$7.2 billion. By 23 November 2013, the total market capitalization of Bitcoin exceeded US$10 billion for the first time.

Commercial use of Bitcoin, illicit or otherwise, is currently small compared to its use by speculators, which has fueled price volatility. Bitcoin as a form of payment for products and services has seen growth, and merchants have an incentive to accept the currency because transaction fees are lower than the 2–3% typically imposed by credit card processors. The largest purchase using Bitcoin as of March 20, 2014 was payment for buying a villa in Bali, worth over $500,000 [1, 5-7].

The Future of the Bitcoin

The future development of Bitcoin needs to face three major risks, namely the national policy, technical security risk and transaction risk.

National policy directly influences the development of the Bigcion in the country. At present some countries recognize Bigcion as legal currency, some countries take a wait-an-see attitude, and some countries have banned directly.

The Bigcion is also facing the development of technical security risk. On the one hand, as the growth of the Bigcion users, circulation scale is more and more large, which will slow down the speed of the system and endanger their own development. On the other hand, hackers, site failure and difficulty for network monitoring of middlemen and other issues may also affect the development of the Bigcion.

And the volume of the Bitcoin market is small, which is very vulnerable to a banker manipulation and exploded slump. The transaction risk is very large.

In a brief, Bitcoin is a virtual currency, with a limited number, non-credit guarantees, decentralization, trading anonymity, globalization and hedging transaction characteristics. Besides, there are also many risks such as difficulties for Bitcoin to be compatible with the existing statutory monetary and financial system, value instability，supervision difficulties, distribution and allocation unequal et al. Let's wait and see the development of the currency.

Risk Analysis of a Large-scale Construction Project

Wenjie Dai[1, a]

[1] Business School, Jiujiang University, Jiujiang, Jiangxi, China

[a]email:68344816@qq.com

Keywords: Risk Factors, AHP, Fuzzy Synthesis Evaluation, Risk Grade

Abstract. Huge investment, long construction period, many risk factors are existed in large-scale construction project. They are faced with various risks intervened with each other. this study using analytic hierarchy process and fuzzy evaluation method, conducts the comprehensive analysis of project risk level, and by combining list sorting method with subjective evaluation method grade the risk factors according to their likelihood of occurrence, the degree of serious consequences, and the controllability of occurrence, so that by the multiplication of three scores, the level of risks can be obtained and corresponding strategies can be established according to these different risks.

Introduction

A. Research Background. The large-scale construction project not only has huge investment, but also has a long implementation cycle, involving a wide range of uncertain elements, economic and technical risks and high quality requirements. Apart from the external political, economic and natural risks, it also meets the technical and non-technical risks in the decision-making and implementation. From the setting-up and complement, the running of the large engineering project must be given great attention to risk management during its entire lifecycle. Taking full advantage of all information gathered in the project management and personnel's management experience, the investor will depend on the assessment of the overall level of project risk as well as its analysis of the results and its circumstances to make investment. And such investment must be ensured to achieve its project goal by developing strategies for dealing with risks.

B. Research Contents. Therefore, investors need to investigate the actual situations of a large engineering project from the external environment, technical and non-technical aspects, by combining qualitative analysis with quantitative analysis formulate the corresponding measures to different risks according to the influence degree of various risk factors. And try to reduce the possibility of occurrence of a risk and its negative effect on the project to ensure the achievement of the goal of construction.

C. Research Methods. The object of the study is a domestic large-scale construction project, which has been put into operation completely. Through the survey and audit of engineering project risk events and technical and economic analysis and combining with project managerial staff‘s ideas. this study using analytic hierarchy process and fuzzy evaluation method, conducts the comprehensive analysis of project risk level, and by combining list sorting method with subjective evaluation method grade the risk factors according to their likelihood of occurrence, the degree of serious consequences, and the controllability of occurrence, so that by the multiplication of three scores, the level of risks can be obtained and corresponding strategies can be established according to these different risks.

Risk Analysis of a Large-scale Construction Project

A. Analytic Hierarchy Process. The main risk in the project management can be summarized as: external environment, non-technical and technical risk three categories. Political risk, economic risk and natural risk are the main external environment risk. Technical risk refers to the loss caused by the uncertainty technical conditions. Including design and construction works. Main risk in project selection, project design, project construction process, to determine technical standard selection,

analysis of the calculation model, the safety factor of the deviation. Non-technical risk refers to the project planning, organization, management, coordination and other non-technical conditions caused the project goals cannot achieve, including purchase, progress schedule, project organizational management, etc. After analysis, establish the AHP model (Fig.1).

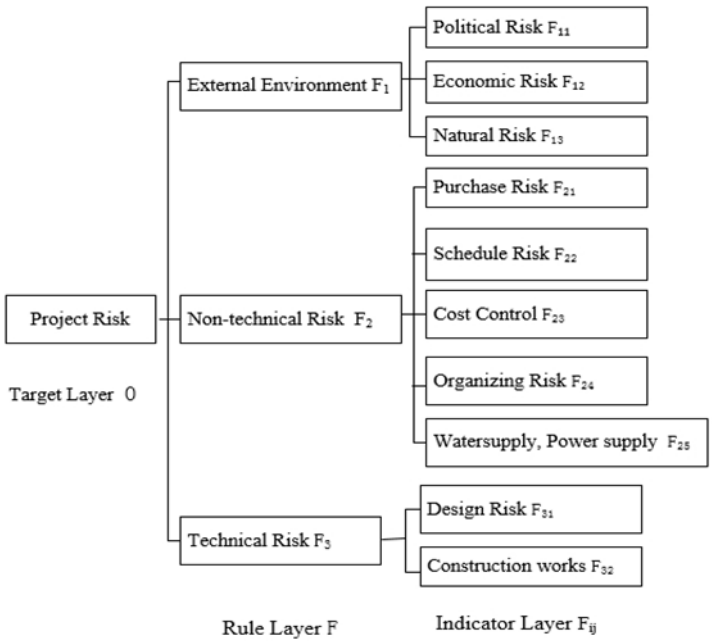

Fig.1 AHP model

The evaluation index system can be divided into three layers: target layer, rule layer and indicator layer. Based on inspecting and studying, a number of experts judge the importance of n indicators on the same layer by Delphi method, then to establish the judgment matrix, and check the consistency. Consistency index is CI=(λ_{max}-n)/(n-1)， according the mean random consistency index RI, obtains relative consistency index CR, CR=CI/RI. If CI<0.1, the weight order meets the requirements, the results are satisfied, or to adjust the judgment matrix, and to obtain the weights again by the above steps [1].

Judgment matrix O－F : $A=\begin{pmatrix} 1 & 1/8 & 1/2 \\ 8 & 1 & 7 \\ 2 & 1/7 & 1 \end{pmatrix}$, λ_{max}=3.035,CI=0.0175, CR=0.03<0.1, the judgment matrix O-F has consistency. W=（0.081, 0.784, 0.135）^{T}

Similarly calculate F_1-F_{1j}, F_2-F_{2j}, F_3-F_{3j}:

w_1=（0.297, 0.163, 0.54）^{T}, w_2=（0.456, 0.056, 0.305, 0.092, 0.092）^{T}, w_3=（0.875, 0.125）^{T}.

Table 1 Weight of the Indicators

Rule Layer	Weight	Indicator layer	Weight	Weight
F_1	0.081	F_{11}	0.297	0.024
		F_{12}	0.163	0.013
		F_{13}	0.540	0.044
F_2	0.784	F_{21}	0.456	0.358
		F_{22}	0.056	0.044
		F_{23}	0.305	0.238
		F_{24}	0.092	0.072
		F_{25}	0.092	0.072
F_3	0.135	F_{31}	0.875	0.118
		F_{32}	0.125	0.017

B. Fuzzy Synthesis Evaluation. Establishing evaluation set V = (V_1, V_2, V_3) = (high risk, medium risk, low risk), Experienced engineering managers analyses different risk factors. calculate membership degree (A_{ij}). Such as the political factor, there are 1 people think is high risk, 1 people think is medium risk, 8 people think is low risk, obtain membership degree A_{11}=（0.1/ high risk, 0.1/ medium risk,0.8/ low risk）,then obtained the results of comprehensive evaluation(Table 4), finally to build the total evaluation[2, 3, 4].

Table 2 Evaluation Results of Various Indicators

Rule Layer	Indicator layer	Membership Degree (A_{ij})	Weight	Evaluation Set V		
				High Risk	Medium Risk	Low Risk
F_1	F_{11}	A_{11}	0.024	0.1	0.1	0.8
	F_{12}	A_{12}	0.013	0.1	0.2	0.7
	F_{13}	A_{13}	0.044	0.2	0.4	0.4
F_2	F_{21}	A_{21}	0.358	0.1	0.7	0.2
	F_{22}	A_{22}	0.044	0.2	0.2	0.6
	F_{23}	A_{23}	0.238	0.7	0.2	0.1
	F_{24}	A_{24}	0.072	0.4	0.4	0.2
	F_{25}	A_{25}	0.072	0.1	0.1	0.8
F_3	F_{31}	A_{31}	0.118	0.5	0.4	0.1
	F_{32}	A_{32}	0.017	0.3	0.4	0.3

$$C = WS \tag{1}$$

$$c_{ij} = \bigcup_k (w_{ij} \cap s_{ij}) \tag{2}$$

w and *s* intersection calculation take the minimum value, *w* and *s* union operation take the maximum value, then

C= [0.238，0.358，0.2]

Grade calculation result is as follows:

B= [1.0，0.5，0.2], $D=BC^T=0.457$

The project belongs to low risk, can invest construction.

C. Risk Grade and Risk Ranking. By combining list sorting method with subjective evaluation method grade the risk factors, from possibility, severity and controllability. Experienced managers with subjective evaluate risk grade from three aspects. 0 represents not risk, 10 represents the greatest risk, by the multiplication of three scores said risk grade. It is concluded risk grade of the risk factors, calculating the correlation degree (r_{ij}) for risk grade in weight.

Table 3 Risk Grade

Rule Layer	Indicator layer	Weight	Risk Evaluation			Risk Grade	r_{ij}
			Possibility	Severity	Controllability		
F_1	F_{11}	0.024	1	1	6	6	0.14
	F_{12}	0.013	0	0	4	0	0
	F_{13}	0.044	1	1	10	10	0.44
F_2	F_{21}	0.358	3	5	5	75	26.85
	F_{22}	0.044	2	1	4	8	0.36
	F_{23}	0.238	10	5	3	150	35.70
	F_{24}	0.072	7	6	4	168	12.10
	F_{25}	0.072	1	8	3	24	1.73
F_3	F_{31}	0.118	8	10	6	480	56.64
	F_{32}	0.017	10	8	5	400	6.80

Risk ranking is r_{31}> r_{23}> r_{21}> r_{24}> r_{32} > r_{25} > r_{13}> r_{22} > r_{11} > r_{12}.

The Construction Project Risk Control Strategies

Investment must be ensured to achieve its project goal by developing strategies for dealing with risks through risk evasion, risk control, risk transfer and risk retention in the construction project.

A. Risk Evasion .When the project's possibility of potential risk is too big and adverse consequence is very serious, in the case of no other strategies to reduce, the initiative to abandon the project or change the project objective and action plan is a strategy to avoid risks.

B. Risk Control. Reducing the facing risk is a kind of positive management means, and project managers who are reluctant to give up or transfer the risks, by minimizing the possibility of loss and adverse influence, can also achieve the goal of controlling. When there is a rainy day, for example, it is impossible to carry on outdoor construction, but to arrange as many as possible personnel and equipment to be engaged in the indoor work is a kind of engineering project risk reduction measure.

C. Risk Transfer. To transfer the risk of loss of the project to other individuals or units doesn't reduce the risk of harm, for it is only to make another party to bear the transferred risk. This kind of risk control measure is mostly used for dealing with such situations that the risk probability is small, but the loss is big, or engineering project organization is difficult to control the engineering project risk. The realization of the transfer of risk, to great extent, depends upon agreement or contract to transfer the loss of legal responsibility or financial consequences to others to take.

D. Risk Retention. Bearing the losses caused by risk accidents and taking the risk retention mainly depend on investors' own management and financing ability. Risk retention and risk control are not the same, because the former is the post-processing of its financial loss after the happening of risk accident, while the latter is the pre-processing before the risk accident so as to change the possibility of risk occurring and the severity of losses when it happens.

In this paper，project manager used risk control Strategies for the construction project.

Table 4 Construction Project Risk Control Strategies

Indicator	Risk Factors	Risk Management Strategy	Risk Counter-measure
F_{11}	Political Risk	Risk Transfer, Risk Retention	Insurance , Claim
F_{12}	Economic Risk	Risk Retention, Risk Transfer, Risk Evasion	Strict contract Clause, Subcontract, Arbitrage transaction
F_{13}	Natural Risk	Risk Transfer	Insurance
F_{21}	Purchase Risk	Risk Transfer, Risk Evasion	Bid guarantee, Prequalification
F_{22}	Schedule Risk	Risk Retention, Risk Control	Claim, Preventive Measures
F_{23}	Cost Control	Risk Retention, Risk Control	Contract Management, Subcontract
F_{24}	Organizing Risk	Risk Retention, Risk Control	Rigorously enforce rules and regulations, Preventive Measures,
F_{25}	Water supply, Power supply	Risk Transfer	Claim, Insurance
F_{31}	Design Risk	Risk Evasion, Risk Transfer	Claim ,Distinguish Responsibility in Contract
F_{32}	Construction works	Risk Retention, Risk Control, Risk Control	Claim, Preventive Measures, Insurance, Rigorously enforce rules and regulations

Summary

In this paper, investors investigate the actual situations of large-scale construction project, through the survey of construction project risk events combining with internal and overseas current information. By combining qualitative analysis with quantitative analysis formulate the

corresponding measures to different risks according to the influence degree of various risk factors, and try to reduce the possibility of occurrence of a risk and reduce its negative effect on the project to ensure the achievement of the goal of construction.

Internet Financial Credit Evaluation for the Small and Medium Enterprises

Yiqing Lu[a]

School of Information Management, Beijing Information Science and Technology University, Beijing, 100192, China

[a]email: luyiqing@126.com

Keywords: Internet financial; Credit Evaluation; Big data;

Abstract. In this paper, a credit evaluation system based big-data is designed to change the information asymmetry between the finance institutions and enterprises, reduce the credit risk of internet financial institutions and investors, by utilizing the information and technology advantages. The research objective of this project have important theoretical and application value to the development of small and medium-sized enterprises (SME) credit evaluation system.

Introduction

In short, in many developing Asian economies, it is not easy for SMEs to do business, and one element of that is that getting credit is quite difficult in many countries.

There are many reasons why access to finance is difficult in developing Asia:

- Large numbers of SMEs are in the informal sector. They are not registered, they do not have all the necessary documentation. It can be difficult for potential lenders to distinguish the financial situation of the company from that of its owners. They are less able to provide collateral.
- Financial markets are underdeveloped in many Asia countries. They do not offer a complete range of financial products and services. They may also suffer from regulatory rigidities.
- The fixed costs of all the paperwork mean that it is easier for banks to make bigger loans to larger enterprises.
- In many countries, large enterprises enjoy privileged access to finance from banks. Many of these banks are state-owned or have close links with the government which uses bank lending as an instrument of industrial policy to develop specific sectors. Banks may also have ownership and other ties to industrial interests and will tend to favor affiliated companies. This means that it is difficult for SMEs to obtain finance.

So, even in normal economic conditions governments have recognized that, to survive and grow, SMEs need specific policies and programs especially to facilitate their access to finance.

Let's move on to the crisis. SMEs and their financing have been especially hard hit by the global crisis leading to massive job losses. For example, Lim reports that over 100,000 factories in southern China alone have closed.

This has occurred as revenues have fallen, and the credit crunch has reduced access to finance for SMEs, which are perceived as riskier, more than for large enterprises. [1-3]

Internet Financial

Different from the indirect financing among commercial banks and the direct financing of stock and bond markets, the internet finance is a new thing generated from the combination of internet and finance in recent years, and is a new financial service mode which realizes funds allocation, payment and information intermediary depending on internet technology and mobile communication technology.

In recent years, new internet finance institutions have been emerging continuously in many regions of China and the market scale has been growing increasingly.

Under such new financial mode, internet and relevant software technology have replaced the professional services of financial and security institutions, complicated transactions such as risk pricing and immunization hypothesis are not only simplified greatly but are also easy to operate. Loans, issuance and transactions of stocks and bonds, and delivery versus payment can be done online directly.

Currently people are lack of investment channels. Being a financing service platform with low risk and high return and easy to participate and operate, internet finance can be easily accepted by the public. Common people can make financial transactions through the internet, the market participants are more popular and the huge benefits brought by the transactions can bring more benefits to the public[4-5].

Internet Financial Credit Evaluation based on Big Data

Concerning the traditional financial institution, there is no difference on the operational cost between the large loan and small loan[6]. For the financial information in the small and medium enterprise tends to be imperfect, it is hard for the bank to accurately evaluate the credit condition of the small and medium enterprise, thus causing the bad debt of small loan is higher and the non-performing loan ratio with the good governance maintaining 3%. Due to the high cost and high bad debt rate, the bank does not pay attention to the small loan for a long term. However, under the Internet finance, using the technical means of big data, cloud computing, data mining and social network can integrate various related data and set a more accurate credit ranking indicator to evaluate the enterprise's credit condition. On the basis, the credit evaluation model based on the big data can be established, as shown in figure 1.

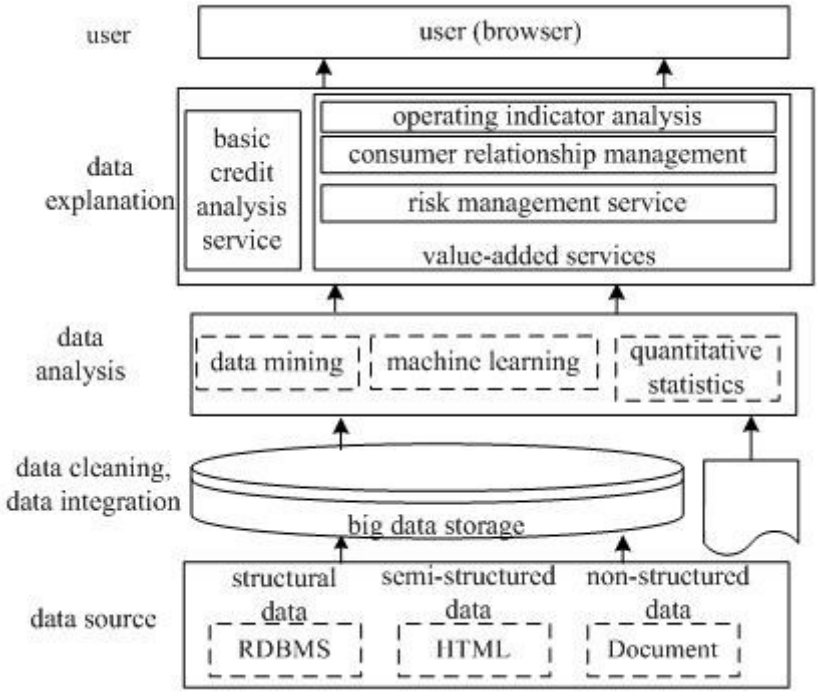

Figure 1 Internet financial credit evaluation

- Large data collection

Under the traditional financial model, the credit institution can obtain limited data, and the accuracy to evaluate the credit of the small and medium enterprise is insufficient. However, under the Internet financial model, the credit institution can collect large amounts of data through the technical means to comprehensively judge the credit condition of the credit object and make a more accurate credit evaluation. There are three main means for the source of big data: 1) When submitting the loan application, the demand side shall perfect the data, submit the information including the company,

family, spouse, education and housing. 2) In order to further improve the data, enhance the data dimension, and improve the risk control level, the external data shall be introduced, such as customs, taxation, electricity, water, telecommunication, central bank credit system and other data, the Internet information of the loan enterprise can be collected and integrated, such as the consumer interaction data and search data in the social platform, etc. 3) Concerning the enterprise developing e-commerce, the e-commerce data can be collected, such as upstream and downstream transaction, consumer data, logistics data, reputation evaluation, certification information, recent trading dynamic, real-time operating condition, platform tool usage status, etc., the data can be integrated and processed.

- Design credit evaluation indicator

The small and medium enterprise's credit evaluation indicator under the Internet financial environment can be established according to the collected big data. Concerning the small and medium enterprise developing the e-commerce, in addition to consider the indicators reflecting the enterprise operating capacity, profitability, solvency and development capacity, the indicators reflecting the enterprise network marketing, network service capacity and network management capacity shall be considered. The credit data shall be analyzed and calculated with the data mining, machine learning, metering statistics and other mathematical methods and models to finally form the credit report of the enterprise.

According to the credit evaluation indicator, the collected big data shall be analyzed with credit evaluation algorithm. In addition to provide the basic credit analysis service, the result can be used for the operating indicator analysis, consumer relationship management, risk management service and historical data management and other value-added services.

College Aerobics Curriculum System Construction in Perspective of Systems Theory

Ying Zhang

School of Education and Sports, Bohai University, Jinzhou, P.R. China

47086132@qq.com

Keywords: systems theory; colleges; aerobics; curriculum system; construct

Abstract. The physical education curriculum is an important part of the school curriculum system, is to achieve the goal of school physical education, quality education, promoting students to adapt to society, students complete an effective way to cultivate individuality. In this study, aerobics as the college physical education curriculum reform and the practice object, on the base of the comprehensive analysis the development status, according to "National College of Physical Education Curriculum Guidelines" spirit, combining with the college aerobics teaching characteristics and rules, system theory is curriculum ideas, from the target system of aerobics courses, teaching content, teaching form, teaching methods, curriculum evaluation, and other aspects, to construct the aerobics curriculum system of higher education. Effectively cultivate student's sports consciousness, physical ability and innovation capabilities, to meet the needs of the student physical and mental health, and lay a solid foundation for lifelong physical reserves.

Introduction

Aerobics in the late 1970s into China, in the 1980s gradually been adopted by the physical education curriculum of college. Aerobics as an emerging sports project, financial gymnastics, music, dance, martial arts as a whole, to physiology, psychology, aesthetics, music and other disciplines theory as the instruction, with its energetic and progressive youthful vitality and aesthetic appreciation, attracting more and more people, the majority of young students like [1]. However, after investigation, many schools are still no clear teaching syllabus and supporting materials, there is no complete teaching system in aerobics curriculum of some schools, the teaching goal is not clear, single teaching content, teaching in the form is boring, Teaching evaluation using a simple technology scoring system, Too dependent on teachers' subjective judgments, not fully checked, assessed the quality of student learning. Based on this, we propose to form and establish a comprehensive system of college aerobics courses, to achieve the teaching content, teaching evaluation and other aspects of the deepening reform measures, to be closer to the actual students and teachers, to meet the needs of the market and the situation, adapt curriculum content needs, to provide a reference for college aerobics teaching reform and promote the construction of college aerobics courses. Construction of College Aerobics Curriculum System is based on training colleges personnel specification requirements, lifelong physical education requirements and spirit of the "Outline" [2], the introduction of the system theory on the college aerobics teaching, it can not only motivate their students directly participate in aerobics teaching enthusiasm, but also significantly improve the aerobics teaching quality.

Construct the Theory Basis of Aerobics Curriculum System

Systems theory is an intermediary theory between science and philosophy. According to the research method of system theory, the research object as a system to consider analysis, in-depth study, can not only focus on the whole and the part (main system and subsystem) research, but also focus on the relationship between the system and the external and the environment, the study of interaction, can fully demonstrate its dynamic, comprehensive, holistic, optimal performance characteristics [3]. The article using system theory on college aerobics teaching research, the entire college aerobics courses as a complicated system engineering, also as a main system, thus the four

subsystems-teaching goal, teaching content, teaching methods, teaching evaluation were to be discussed (Fig. 1).

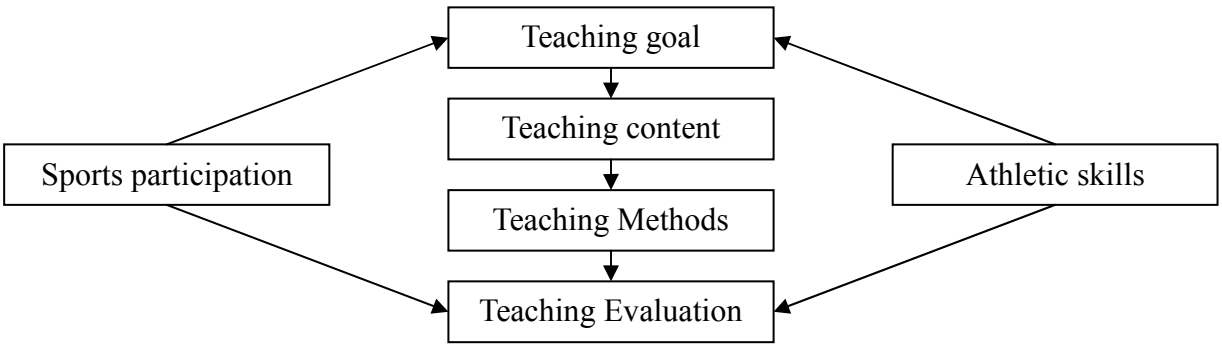

Fig. 1. Aerobics course system structure diagram

Aerobics Curriculum Goal System

The curriculum goal is the reflect of certain educational values in curriculum field [4]. In the 2001, "curriculum standards" explicitly pointed out the sports classroom learning goal is "to participate in sports, sports skills, physical health, mental health, social adaptation" (Table 1). Aerobics curriculum teaching goal is in a short period of time to allow students to acquire the skills and knowledge, to enhance students' interest in aerobics sports, to cultivate students' consciously exercise habits, laying the foundation for lifelong sports.

Table 1. Aerobics course goal system

Content	The basic goal
Sports participation goal	To actively participate in aerobics exercise and form the habit of conscious exercise Understanding the designing principles and methods of aerobics, learn to complete aerobics choreography, and can make personal fitness program Understand aerobics competition rules, has a certain ability to appreciate the aerobics performances or competitions
Athletic skills goal	Develop athletic ability of students to participate in the aerobics Master the basic method of aerobics, the teaching method and the physical quality training method Master several sets of aerobics or popular gymnastics Master disposal method of common sports injuries
Physical health goal	To develop good habits, to form a healthy lifestyle Self-evaluation on fitness effects Can reasonably choose the personal food of health and nutrition
Mental health goal	To develop good habits, to form a healthy lifestyle Self-evaluation on fitness effects Can reasonably choose the personal food of health and nutrition
Social adaptation goal	Exhibiting good sportsmanship and teamwork spirit Correctly handle the relationship between competition and cooperation To enable students to have the courage to perform, good performance, with modern consciousness

Aerobics Teaching Content System

Aerobics teaching content system is a subsystem of physical education teaching, according to author's own teaching practice, put forward the aerobics college teaching content system of fit fact: Select informative content, select the skill content, and select operability content. Meanwhile, the establishment of "hierarchical teaching" (primary, intermediate, senior) teaching model, According to the number of students and the different of basic level, to carry on the hierarchical teaching,

primary open “basic course”, intermediate open “improving lesson”, senior class open “selective course” and “ popular project additional lesson”.

Basic Course (primary) teaching settings: students master basic skills of aerobics and related theoretical knowledge. Improve lesson (Intermediate) teaching content settings: the students' favorite hip-hop, Latin aerobics, prosodic fighting, physical training and other content introduced into the classroom, using the “segmented” teaching, teaching content is segmented to arrange. Any selective course (advanced course) teaching content settings: Latin aerobics, hip-hop, rhythm fighting, physical fitness training and other fashion content introduced into the classroom. In the implementation process of the new aerobics teaching model, to fully reflect the leading role of teachers and the main role of students. So that different levels of students to fully enjoy every aerobics class, and get a good emotional experience in aerobics teaching

Aerobics Teaching Method System

Teaching methods include teaching means and organizational forms, is to achieve teaching goal and improve the teaching quality to service [5], the scientific teaching method could promote the rapid formation of student proficiency and rational use of skills, to achieve effective teaching results, so as to inspire and cultivate the students' interest in learning, and enhance the confidence to learn aerobics, achieve the purpose of lifelong physical education. In aerobics teaching, just by changing the traditional teacher lectures and demonstrations to teach students basic skills teaching methods and action routines, and more use of multimedia teaching, the abstract transform into concrete, so that improving the students' consciousness of participation and learning initiative [6]. Meanwhile, in the process of teaching, give full play to students' dominant role, based on mastering certain actions, according to the law of creation of action, inspire students to create sets of aerobics. In addition, in order to promote examination by competition, in order to promote competition by examination, is also a bright spot in process of college aerobics classes teaching. This not only gives students the opportunity to test their aerobics technical level in aerobics course learned, to improve their capabilities, also can cultivate the students' competition consciousness, make the students have confidence to show themselves, and have the team spirit of unity and cooperation.

Aerobics Curriculum Evaluation System

With the development of modern science and sports science education, more and more fields have begun to use control theory, information theory to study the evaluation system [7]. Because of individual differences in evaluation objects, evaluated from the perspective of a single evaluation steering multi angle and more comprehensive quality assessment method, implemented at different levels of hierarchical assessment, and establish the combination between student end and the process evaluation, combining the multiple evaluation, qualitative and quantitative evaluation of the combination, have been a major evaluation system of aerobics courses (Fig. 2). Thus having the comprehensive evaluation to learning process and learning effect, to form a evaluation system that not only pay attention to process evaluation and focus on the effect evaluation, dilute the evaluation of the selection function, strengthen comprehensive education, testing, feedback, encouragement integrated functions.

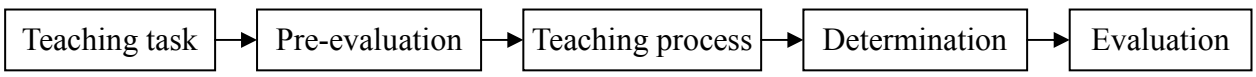

Fig. 2. Aerobics courses evaluation system

(1) Combined with the end and the process evaluation. Pay attention to the result evaluation. At the same time, is more attention to process evaluation, evaluation of learning attitude, active participation and innovative evaluation. Emphasis on the development and progress of the student's own magnitude, so that every student can give full play to their strengths, make up for their

shortcomings, encouraging progress, especially pay attention to the special situation of the individual differences and weak students, so that every student has the progress of confidence.

(2) Multiple evaluation. From the multi angle, multi method, multi form to do a comprehensive evaluation, fully enhanced guidance, education, experience, feedback, identification, specification, deepen and incentive comprehensive functions. On examination content, to highlight the capacity and quality assessment on the basis of theoretical knowledge assessment; in the examination ways and means, to strengthen the functions of the various ways and means, advantages and disadvantages the reasonable combination, and form scientific and reasonable evaluation mechanisms.

(3) Combined with the quantitative and qualitative evaluation. The physical shape, physiological functions and exercise capacity, which can be measured data to determine the human body development. The student sports attitude, morality, psychology, exercise capacity and other indicators, there is a lot of humanities factors, with a significant qualitative characteristics, it is difficult to quantify, can take a qualitative evaluation or fuzzy comprehensive evaluation method.

Conclusion

This study were from five aspects of sports participation, sports skills, physical health, mental health, social adaptation to do the detailed description of aerobics curriculum content. Recommended that future seriously learn the advanced experience of foreign countries, insist integration and optimization of the overall curriculum system, construct with a reasonable, flexible curriculum areas and course modules, courses for schools and students to enhance the adaptability , so as to promote the reform and development aerobics curriculum system.

Keywords: Logistics; Yinyan Logistics Base; Development; Case Study

Abstract. Logistics in China is on its rapid development stage as more and more distribution centers and logistics bases were established. However, due to China's specific national conditions, there are some problems existed in logistics compared with the international logistics. Research on the problems existed in logistics bases will help to find solutions to the logistic problem in China. Therefore, the paper analyzed the status and development measures of China's logistic bases taking Yinyan logistic base in Jiangxi as an example to do an primary research on the development strategies of logistics bases in China.

Introduction

With the development of logistics in China, logistics bases are beginning established in China. In fact, logistics base in a new form of logistics with its development to a certain degree[1], also it's a result of logistics developing[2] . To response the requirement of modernization in China, the government formulated policies on the construction of logistics bases to promote the development of logistics in China. Many provinces began their constriction of logistics bases[3]. As more and more logistics bases are built, researches on its status and efficiency is important so as to examine the real condition of logistics in China. Jiangxi Yinyan logistics base is a logistics base with freight, display and storage functions which achieves the third-party logistics requires while using modern electronic systems for the majority of enterprises to provide a good trading platform. The base is divided into four sections as display area, storage area, LTL(less than carload) distribution area, and information trading center. The purpose of Yinyan logistics base is service the nation based on the central region, and truly achieving the goal of smooth flow of goods through the world.

The paper analyzed the status and development measures of Yinyan logistics base in Jiangxi to find out the real situation of logistics base and to provide advices for the development of logistics bases in China.

Status of Yinyan logistics base

Yinyan logistics base is located in the east of Shengmi Brige of Nanchang, Jiangxi province. It is near to Nanchang University and has a convenient transportation, and it's one of the biggest logistics bases in Jiangxi province which has a 320,000 square meters covering and 270,000 square meters total construction area. It is invested by Beijing Cheng Yi Co. Ltd with a funds of 20 million Yuan, is one of the key investment projects in Jiangxi Province. The total investment to Jiangxi Yinyan logistics base is 300 million Yuan with a covers of 477 acres located in the Xihu District of Nanchang Chaoyang farm in order to build the largest logistics base in Jiangxi Province.

The strategic orientation of Yinyan logistics base is: make Yinyan logistics base be one of the mainland's transit station for Yangtze River Delta, Pearl River Delta and Fujian Delta to enter the inner land based on Nanchang as the foundation. It can pull the construction of Nanchang city from the establishing of Yinyan logistics base to build a domestic and international logistics hub nodes with a system constitute of road, water and air transport while making the road system as the main transportation means. The corporation vision of Yinyan logistics base is: Jiangxi Yinyan Company

Limited will accelerate the construction of logistics infrastructure and high-tech logistics technology and equipment, improve the base supporting aspects, introduce professional management personnel, and establish a logistics system relatively synchronized with advanced international logistics industry to provide a platform and a logistics base with high quality services for enterprises. What's more, Yinyan will expand exchanges and cooperation with their counterparts in the international logistics companies to achieve multinational operations, will stream into the international market and promote the international development of the logistics industry and will improve the development of logistics in China from all aspects after it is established.

In fact, the real statuses of Jiangxi Yinyan logistics base are shown as following:

(1)The logistics base in Jiangxi Yinyan is made up of numerous small-scale logistics companies, each company operates on its own rules, and the chances of information exchange and cooperation between them are few.

(2)Each company's logistics facilities is outdated, small-scale and scattered. The management is traditional and relies on manpower with low specialization degree. There is no high-tech operation and information management system.

(3)The socialization and organization level of each logistics company is low, and the convergence on various aspects of logistics and distribution is poor. Few companies among Yinyan logistics base can provide one-stop services.

(4)Most companies use logistics information mainly stay in the level of collecting and transmitting information, few of them know about the operation and its significance of analysis and data mining for logistics information.

As it can be seen from the above real status of Yinyan logistics base, it's more like goods transfer station than a real logistics base for it has a big gap with the real logistics distribution center especially with the developed distribution center. The utilization of logistics technology and logistics systems in Yinyan logistic base is beyond the average level. With the lack of special information management system, the base has a low informatization level. Of course, this has a great relationship with the status of China's logistics development. The real statuses of China's logistics development are: low operation level; low economic benefit[4]; uneven development[5], the east has a better logistics performance than the west and Midwest; rarely exchanges of logistics technologies and information between different regions. As logistics is on its development stages in China, it need time and experience to improve the status of logistics development in China.

Development Measures for Yinyan Logistics Base

To improve the status of Yinyan logistics base in Jiangxi, there are many works need to be done to make it a effective logistics base in China even in international logistics field. For logistics distribution center of Yinyan logistics base, it should learn from the experience of developed countries and take use of modern facilities[6], starting from the consideration of national, region and business situation for it, to develop a logistics base with its own characteristics.

Establish a comprehensive information exchange processing center. Yinyan logistics base should rectify all enterprises within it, unite all business information among its sub-centers to create an integrated information processing center (as shown in figure 1). It can use some computer software and systems, such as information management systems and decision support systems to strengthen exchanges between enterprises[7], and to improve the delivery and utilization of logistics information management effectiveness. If there is information that will benefit to the development of the company or information about collaborative works needs to work together, each sub-company can find collaborators by using the internal information management system to seek common development with its collaborators. From this way, the utilization of resources this can be enhanced, and it will promote the development to the logistics base.

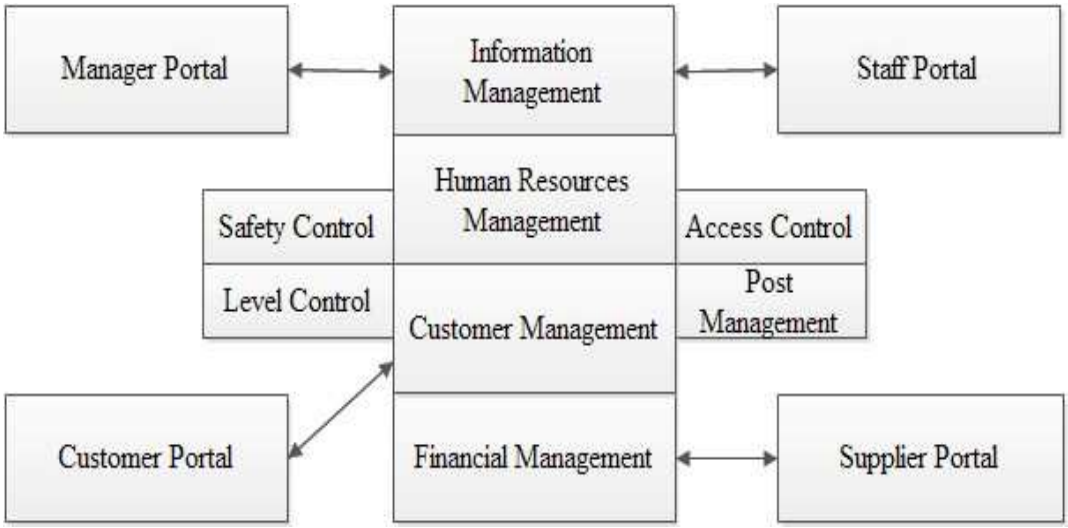

Fig.1 Information exchange processing center for Yinyan logistics base

Introduce technology and equipment to improve the technological level of Yinyan logistics base. From the construction of an automatic three-dimensional warehouse, the purchase of advanced logistics and material handling vehicles, and the introduction of information technology to make up of an advanced information technology system for logistics base; Of course, to make up an advanced information technology system, the initial investment is huge which may need the support of national policy or foreign investment. The specific introduction and establishment of appropriate advanced technology and equipment should also combine with the real conditions of Yinyan to improve its information management level in a feasible way. For example, what kind of information management system to be introduced or what kind of information should be collected and how man new professionals on information management should be employed, and son on, all these questions related to the real effectiveness of the new introduced information technology system. With the help of the new information management system, Yinyan will improve operational effectiveness greatly. There are automatic identification technologies, EDI technology, geographic information technologies in physical information systems will help to effectively improve the work efficiency for Yinyan logistics base.

Improve the quality of its staff. Yinyan logistics base has an advantage that near major colleges and universities of Nanchang which will benefit it to abort high-tech talents with a relative less economic cost. With rapid economic and technical development in this era[8], a professional of a filed is playing a more and more important role on the development of the economy and society. As to Yinyan, it should make efforts on improve its personal quality by to attract high-tech talents or tanning on its original staff to fit with the development needs of it. With the reasonable use of its advantages, the status of Yinyan Logistics base will be improved to a great extent with a certain investment on this part.

Summary

From the current development situation of Jiangxi Yinyan, we can see that it has a long way to achieve its goal to be a domestic and international logistics hub node. Also,, we can see that though many provinces are engaged in building its logistics bases to response to the call of the national policy, the development situation of these logistics bases is uneven and not optimistic, there are still many problems of logistics bases in undeveloped cities like Jiangxi, as Yinyan logistics base is its biggest logistics base. With the rapid development of information technology today, logistics bases should pay their attention on the investment and application of high-technology and information management system. As to Jiangxi Yinyan logistics base, the managers should seize the opportunity to absorb the advanced technology and experience to have a steady progress, and be vigilant at all times on the major problems of its own during the rapid development of it. Yinyan logistics base seize

the opportunity to develop, it is reasonable to believe that the development prospects of Yinyan logistics base is very optimistic.

Keywords: .Industry Information; service; transformation; Discussion

Abstract. In the context of building an innovative country, innovation and development-oriented enterprise transformation and restructuring of industry information services, creation and innovation for our country to adapt to national construction industry information service system has a theoretical guidance.

Introduction

In January 2006, the CPC Central Committee and the State Council's decide to build an innovative country. Building an innovative country, the core is to enhance the capability of independent innovation as the strategic basis for the development of science and technology [1], out of the path of independent innovation with Chinese characteristics, promote leapfrog development of science and technology. The Core is to enhance the capability of independent innovation as the adjustment of industrial structure and changing the growth mode of the central link, building a resource-saving and environment-friendly society, promote rapid and healthy development of national economy. Core is to enhance the capability of independent innovation as a national strategy, through to all aspects of modernization and inspire the whole ethos of innovation. And train high-level innovative talents, to create favorable institutional mechanisms for independent innovation, and vigorously promote theoretical innovation, institutional innovation, and technological innovation, continuously consolidate and develop the great cause of socialism with Chinese characteristics. Based on our background of building an innovative country, the development of innovation-oriented enterprise transformation and restructuring of industry information services[2], require the creation of nation-building and innovative information services industry to adapt to the system. As of 2013, China-based telecommunications industry presents the following basic features:

First, industry revenue grew steadily. Near the first half of 2013, China-based telecom services revenue grew by 8.9%[3], the growth rate dropped 0.3 percentage points over the same period last year, higher than the same period GDP growth of 1.3 percentage points.

Second, the data traffic class outstanding contributions to business income, and the proportion of non-voice revenue increased gradually. Non-voice revenues in the telecom business income accounted for more than 50 percent of telecom services revenue contribution of over 90%, basic telecom industry gradually transition to an integrated information service operator.

Third, 3G mobile phone users exceed 300 million firstly and fusion class of business to take shape. As the industry continues to transition and information services industry continues to promote cross-border integration, industry converged business has begun to take shape.

Fourth, broadband Chinese special action and proved to significantly increase broadband consumption.

Fifth, the traditional mobile business spending fell significantly, and the business gradually becomes saturated.

Sixth, the rapid development of mobile Internet traffic operations gradually forms a new model. Gradually saturated with traditional business is relatively rapid development of mobile Internet-related businesses. Mobile Internet data traffic related to rapid growth in business spending [4], promote the rapid development of mobile Internet applications store this rapid development of

traffic management based on new business models, new business operating model based on data flow is gradually advancing exploration.

Seventh, the Internet industry is flourishing, growing industrial scale.

Eighth, the effect is obvious investment-led, coordinated development of information and communication industry chain. In the context of the rapid development of mobile Internet, the various operating companies are closely cooperation with the upstream and downstream industry chain manufacturers.

Questions and Problems

Our national innovation-oriented information services industry restructuring and development compared with developed countries, which have their own advantages; there are problems to be solved. Transformation of industry information services major problem exists in five areas:

First, the main trade association for the information service system failed to establish industry, industry associations' mechanism needs to be established. Also need to rationalize the relationship between trade associations and government functions of management, the establishment of government-led trade association system under the supervision of planning and information services.

Second, the role of industry information services to protect innovation and development in the industry is not clear; especially in the industry sector organization information service system is decentralized, disorderly development of the state. Multiple centers in an industry often overlapping construction, operation and service efficiency is not high.

Third, after the successful implementation of the institutional reform of the State Council, the reform of the information service industry innovation and development of the system to be further deepened, industry information service under the auspices of the State can not guarantee institutionally. Meanwhile, the relationship between technology and economic information services, industry bodies and government services to be further rationalized.

Fourth, international trade information service, open technology needs to be strengthened. EU countries and the EU in order to promote the common development of economic globalization, the information real common market plan, promote regional cooperation, so as to enhance the capacity of countries to enterprises and service levels. This experience can be used in the restructuring of industry information services.

Fifth, information services and developed into comparative industry, there is a gap. Especially the reform of government institutions has led the industry into the relationship between changes in information services, information services industry, there are mechanisms to adjust and change into question[5], the key to solving the problem is to seek diverse and innovative development of enterprise investment system to adapt.

Sixth, macroeconomic uncertainty poses serious challenges to the industry. World economic situation is still complex and deeper impact of the financial crisis and the debt crisis continues to appear. Worldwide rise of trade protectionism, trade frictions spread from the previous labor-intensive industries to technology-intensive industries, China's enterprises raise security question, etc., that will have a profound impact on the development of the industry.

Seventh, the New Deal and taxation of business changed to increase bring challenges to the development of the industry. The original intention of this program is to address double taxation[6], but in the beginning of the implementation, as telecom companies' current difficulties in obtaining tax-deductible invoice operations, may cause periodic increasing rather than reducing the tax burden, resulting in industry revenues and profits decline. Meanwhile, the new tax reform is bound to drive the way the telecommunications companies to adjust financial systems and business processes, changing its inherent sales model.

To build an innovative country, industry information service organizations should be based on information technology and economic globalization, in order to enhance the capability of independent innovation of China's industry, the core competencies and capabilities for the purpose of international development. The authors therefore believe that it should be explored from reorganization under five in the transition process: First, give full play to the advantages of our

system, strengthen the government's management of industry information services[7]. Second, industry information service system reform, specifically the role of government, industry associations and other subjects, in order to build government-led trade association as the main form of socialized industry information service system. Third, the government department in the information industry and industry associations belongs to realize two-track operation, emphasizing the public service, while actively explore the market-oriented services. Fourth, the development of the industry information service, rationalize the relationship between the relevant industry[8], to co-organized way, construction industry group information network, while achieving national and regional trade information network linkage. Fifth, concern legal construction industry information services, communication services industry institutionalized and standardized.

Development measures

For innovation and development of organizational change and restructuring industry information service, the basic structure shown in Figure 1.

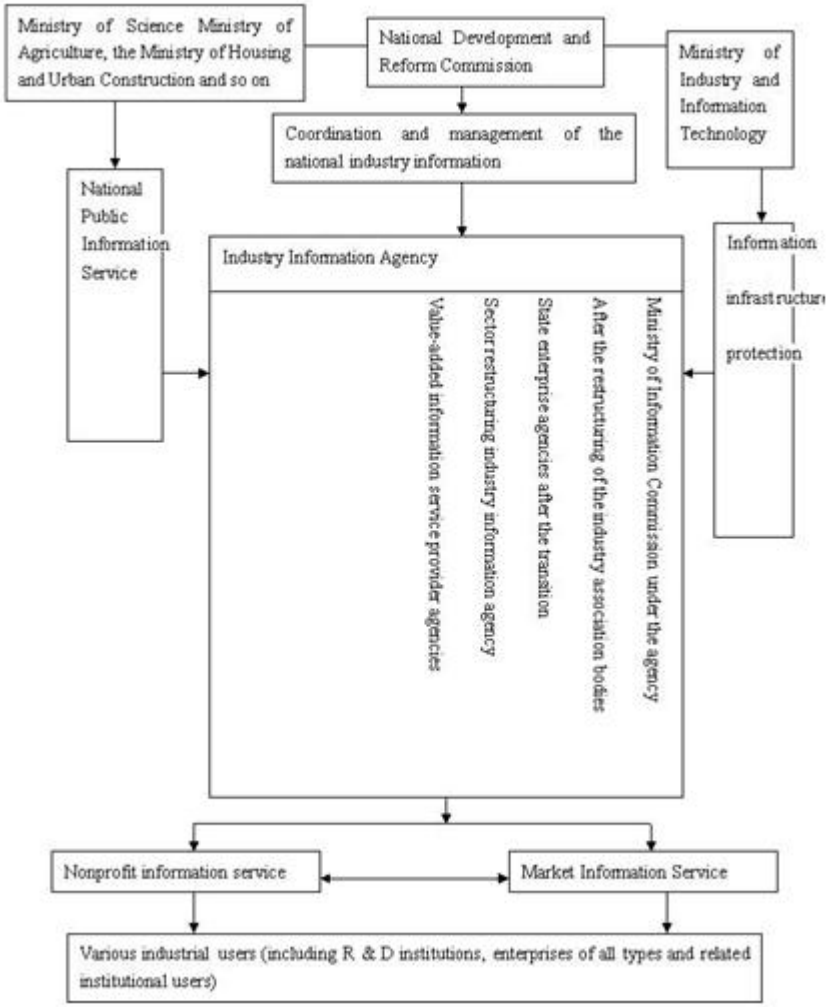

Fig.1 China's information services industry restructuring and reorganization Structure

The figure shows two meanings: First layer: the management do accountability and each perform their duties. First, the National Development and Reform Commission undertake overall planning tasks, its establishment of a national agency coordination and management information services industry specific information agency coordinating the operation of the various sectors; Second, the competent authorities undertake a national public information service only straight pipe tasks and achieve public agency sharing of information and industry information; Third, the Ministry of Industry and Information Technology bears only the information technology infrastructure in charge of the responsibility to protect, and provide support for industry information agency. Second layer: do the paid services and free services to run dual track parallel form interaction for government, industry

and the public welfare services, will form part of the service paid into the implementation of market-oriented operations.

Summary

China is building an innovative country in 2006 the National Conference on the development goals. To build an innovative country information services industry restructuring and development as the starting point, in the context of building an innovative country, from strategic positioning information services industry starting prominent strategic position in the information services industry innovation and development in the country, based on our industry Status information services, analyzes the advantages and problems of industry information service system, the proposed development of the industry information service transformation and reform and restructuring of countermeasures.

Of course, the information center for the Chinese industry innovation and development network backbone over 120, belonging to the State Council ministries (Commission, Council), industry associations, state-owned enterprises, research institutes and universities, such as, in fact, China's various industries for different scale National and local industry information service network of different affiliations and different management system has reached thousands. With the rapid development of digital, networked, the new industry-oriented information services have mushroomed in the fore, in this context, the Chinese construction industry information service transformation and development of innovation-oriented country, not just involve a small number of key Information Center network, considering the information services industry restructuring process should be more co-ordination of new information services network into account, this can only be more comprehensive.

Keywords: Retail Business; Risk; Distribution; Management

Abstract. Distribution of logistics plays an important role in the modern market, and the distribution of retail has its own unique characteristics and needs. The economy market of China has been developed with an amazing speed. But there are weakness and risks in the market compared with the developed countries, thus it need time and practice to increase the management level of economy market in China. Since the development of the market will bring risks and anti-changes to business, enterprises should prepared for the challenge. The paper analyzed successful cases of retail business to provide advices for retail business in backward areas to prepared for market challenge and risks in order to promote the development of local retail business in backward areas in China.

Introduction

The development of Chinese retail business has followings characteristics: early beginning, slow-growing and small-scale. Under the impact of a global internalization, retail business of China is weak and small with few market shares in the vast market of China. Coastal area cities have an international level of economy market which has a clear market structure influence by modern economic mode, while market in the middle and west of China is under developed which is still exploring its development mode. The difference is caused by the management level of these two groups. The coastal areas begin its modernization in the early 90s in 20th century while the development of middle and west of China is later than coastal area. As China continues to accelerate international integration process, the Chinese market will inevitably meet the full impact of the world economic tide. Thus, research on market of inner land is very important as to increase its competition power.

Retail business has following characteristics :(1) Small order quantity, numerous retail chain stores[1], high order frequency, and time requirements. In order to meet with the consumer demands and product quality, products which difficult to preserve and have intensive needs will have to deliver three times a day. (2) Wide range of goods and diverse forms of transport and storage needs. Faced with numerous types of goods distribution and different goods have different characteristics, it requires different storage forms and transport forms[2], such as frozen, fragile and so on. (3) High frequency of price changes. That is the purchase price of the products has a quick price changes, usually the price of fast moving consumer goods in supermarket chain operating changes rapidly according to the supply and demand in market have also frequently manufacturers or retailers often change due to promotional prices. (4) Returned goods. The distribution center needs to cope with gifts, return goods and other issues. (5) Open stock. Distribution center need to unbundled and sort the bundled goods provided by suppliers according customer orders. (6) Replacement. As the obsolete frequency of goods in retail business is high[3], it need increase new products timely and obsolete dead stock. The paper takes Dazhang distribution as an example and analyzes its status and distribution characteristics to explore survival road for local retail businesses in relatively backward areas and to provide advices for retail business to face with fierce competition in the future.

Distribution Status of Dazhang

The distribution centers of Dazhang locate in Wuhan road, covering nearly 100 acres which provides an important support to the development of Dazhang. Its distribution center played an important role in against the SARS and the snow disaster in 2008, and provided an important safeguard to protect people's lives which benefit its performance increasing in recent years. According to its business needs, Dazhang built its second distribution center with higher information management level in 2009, covering 300 acres, which provide perfect fresh sorting, safety testing, refrigeration and wholesale distribution for the company. Currently the merchandise, food, fresh, clothing and many other basic commodities of Dazhang achieve its purchasing in the original manufacturers or origin all over the country.

The dense shop setting and convenient information network of Dazhang facilitate the implementation of efficient distribution, which make it has advantages like convenient transportation, safe, high-quality, low price, good service,and so on, and set a good image for Dazhang among consumers. The paper analyzed the general framework of Dazhang distribution centers with its three sub-centers instead of its detailed distribution centers setting. That is we analyze the information system network which make up of three sub-centers,that is, fresh, clothing,and general merchandise and food departments. Fresh and cooked food implement a delivery principle of distribute it three times a day among the urban distribution, while other goods distribute according to its sales. The distribution methods for distant areas are different.

Characteristics Analysis of Dazhang Distribution

By analyzing the development process and store location of Dazhang, we summarize several key features of its distribution combined with the analysis of its management strategies:

(1) Distribution methods combine joint distribution and refining distribution. Joint Distribution is suitable for the distribution of high frequency, multi-species and small units goods to save the overall time and cost savings on goods and improve its efficiency greatly.

(2) Clear label division and best route choosing of distribution management. With years operation of Dazhang, it has been quite familiarity with the local geography,the road transport and the community location which make it have their own perception and management strategies on distribution management, and make resources distribution much more effective. By the distribution advantages, the distribution punctuality is guaranteed.

(3) The earlier introduction of information systems than other retail companies. This makes Luoyang Dazhang has formed their own competitiveness before international giants settled in Luoyang. Especially in the supply of fresh food, it has l much more effective distribution operations as Dazhangs' information system terminal has been extended to the major local fresh food manufacturers systems which is commendable in undeveloped area.

(4) The appropriate location and scale of distribution center. The distribution center of Dazhang located in Wuhan road, and it is near to Longhai Line in its left and near to Lin-Ning-luo high-road in its right while it's close to raw market but not overcrowd. Built in 2003, the year before the full liberalization of the domestic retail industry, the high starting point and functional clear of the construction Dazhang's distribution center bring a rare opportunity to it.

(5) Close relationship with suppliers and responsibility of inventory and distribution departments upwards transfer. Dazhang focuses on fresh food supply, and its supply side is mainly concentrated in the vicinity of several large suppliers or supply areas. Dazhang makes its ordering plans with risk analysis and demanding analysis in future market based on data analysis through its information systems. By this distribution method, the inventory and distribution tasks of considerable amount of goods or special goods can be transferred to the suppliers ,and ensure the freshness of the product.

Disadvantages of Dazhang distribution

The main disadvantages of Dazhang's distribution are:(1)Distribution management is not standardized in some distribution processes. Some distribution process is mess and repetition which reduced the distribution efficiency; on the other hand, personnel arrangements are casual and responsibility is not clear.(2) High distribution costs. Vehicles return empty wasted vehicle resources; the mixed using of human resources and equipment resources in distribution center is not conducive to take advantages of their own strengths which will resulting to a double waste of the resources, and is not conducive to reducing costs.(3) Limited distribution capacity. Dazhangs only has two distribution centers, the single scale level of each center is limited and its distribution capacity and automation level is much lower than that of international enterprises.

New Features of Distribution in Retail Business Development

The new features of distribution in retail business development are shown as followings:

(1)Distribution center of retail business will increase or strengthen the distribution function [4]of freezing or fresh food.With the increasing competition in the retail market and the improvement of peoples' living standards, there is a increasing demand for fast food, semi-finished products of fresh and frozen food, and it's a logistics trend for large retail enterprises to set up food processing centers and distribution centers[5]. For example, specializing logistics and distribution companies for meat, eggs, milk, bread and other fresh foods distribution will be formed as a multifunctional logistics center with functions like logistics, refrigeration, packaging, distribution processing, distribution as the living standards of people improved and their requirements on product quality increased

(2) The introduction of third-party logistics. In Japan, about 30 percent chain enterprises rely on the professional distribution companies in a large extent. With the the rise and mature of professional logistics companies in society, retail chain logistics and distribution work transfer to a professional logistics company will become an option for chain enterprises.

(3)Standardization of Distribution center operational processes. Retail vitality lies in its strong normative and normative. Chain operations achieve its scale economies through principles of standardization, simplification while standardization is also an important means of logistics management and it plays an important role on logistics costs and benefits .

(4)Re-construct of logistics information systems. Logistics systems of Chain enterprises related to information systems including internal information management systems and data exchange Systems with suppliers or an electronic ordering system[6]. With the popularization and promotion of e-commerce, retail enterprises, especially retail chain enterprises begin data transfer and ordering online by using of Internet and logistics distribution center, and selling and inventory information of shared goods by upstream suppliers to provide collaborative support for electronic order, commodity inspection, returns, promotion, price change, settlement, payment and other sectors.

Proposals for Distribution of Retail Business in Inland of China

The work of retail business is complex, and the functional of information system is highly integrated[7], thus it requires personal with high quality to be qualified for the work. It need employers of retail business take personal quality into consideration when make strategy project for their enterprises. As the development of retail business is highly dependent on information transmission, the more strategies on attracting professionals or training their staff, the longer running of the enterprise.

Improve distribution efficiency according to the adjusted position of the supplier under the enterprise status will benefit the retail enterprises. As the scale of company expanded, and the changing of distribution range, companies should re-evaluate its supplier according to its distribution demand and suppliers' distance with the market which will reduce distribution costs by reduce the frequency of vehicle empty return.

The redesign and standardization of distribution process can help retail enterprises reduce its costs . Regularly evaluate the efficiency of each distribution business conduct. From product damage, punctuality, operating costs, the degree of satisfaction with various aspects of the evaluation branch distribution, and analysis of each distribution chain efficiency one by one to optimize distribution processes and reduce operating costs. Strengthen the standardization and specialization construction of distribution centers to improve the handling capacity of distribution center.

Flexible management of retail enterprises will help to increase human creativity. Information management is not a simple computerized manual operation[8], but a to new business model by using information technology to build a new information platform. Human resources play an important role during information management as the system running dependent on human-being.

Implement information integration to form a chain operation net and accelerate demand response speed can improve service quality of retail enterprises. The golden rule to the retail industry is to provide high quality services. The golden rule to the retail industry is to provide high quality services. High degree of information integration can accelerate response speed of demand and improve demand forecasting accuracy to enhance the competitiveness of enterprises.

Summary

High degree of information integration can accelerate response speed of demand and improve demand forecasting accuracy to enhance the competitiveness of enterprises.

The economic development of China inland is uneven which provides a basis for the development of small and medium enterprises with Chinese-style. The retail model need subject to market demand. On one hand, it need to find the market characteristics to choose their own way of running business; on the other hand, it need to improve the ability of predicting the market and scientific management according to the international market trends. This paper argues that relatively backward areas need to cultivate powerful medium-sized enterprises to develop its retail business, and to cultivate more local targeted core competitiveness. Distribution is the core of the retail chain, and efficient distribution center is the premise of protecting the supermarket chain to achieve efficient operation. We need retail operations as a whole from the perspective of integration while combined the distribution software and hardware facilities, staff quality and operational characteristics of local market with each other to improve its service quality and competitiveness with scientific information management of retail enterprises. The retail business can survive from exploring and developing its own local advantages to away from the advantages of international retail business when faced with fierce competition in the future.

Statistical Analysis on Primary and Secondary School Digital Disaster Education in China

Mao Shujuan[1, a]

[1] School of Education, Jiangxi Science & Technology Normal University, Nanchang, Jiangxi,China

[a]cnliu2010@163.com

Keywords: . Statistical Analysis; Primary and Secondary School; Digital Disaster Education

Abstract. Along with the progress of human society, the disasters in human society are becoming more frequent and more serious but the situation of primary and secondary school on disaster education in China is not ideal. The paper verified the viewpoint from the analysis of surveys on the theme retrieved through the first data. The paper included some main problems on digital disaster education and proposed an improvement strategies model to improve the situation.

Introduction

Along with the progress of human society, the disasters in human society are becoming more frequent and more serious. Increasingly prominent disasters continue to cause great concern of social sectors. In the current context, Digital Disaster Education has increasingly become an important research topic in this age, and it is urgent to increase the awareness of disaster prevention and mitigation among the whole people including primary and secondary students. To enhance Digital Disaster Education in the whole society and to improve the nation's disaster awareness and the level of scientific and technological knowledge have become the strong tone of the era. Frequent disasters happen in China. And the teachers and students more or less lack the disaster literacy to a certain degree, casualties are most concentrated and most serious disasters in the schools when a disaster occurs. Therefore, in order to reduce the losses brought about by the disaster to the school, investigating the digital disaster emergency education in primary and secondary schools and understanding the status of Digital Disaster Education and finding the perfect strategy for the situation is required and it is the trend.

Exploring the digital disaster emergency education status and problems in primary and secondary schools, and seeking effective measures can enhance disaster literacy of teachers and students in primary and secondary schools and reduce the disaster damage to a certain extent. And primary and secondary students are the hope for the future, their knowledge and comprehensive literacy is directly related to the future of the national quality and the national spirit. The nation's hope lies in young people, in order to improve the national disaster prevention and mitigation ability and enhance the civic disaster literacy, it must be started from the primary school students. Therefore, digital disaster emergency education in primary and secondary schools also contribute to improving the comprehensive national strength and quality of the nation.

The Key Points of Primary and Secondary School Digital Disaster Emergency Education

Digital disaster emergency education in primary and secondary schools has a great realistic significance, it responds to the realistic needs. It plays an important role in the growth and development of young people, as well as in improving the future quality and development of society.The teachers and students in primary and secondary schools to varying degrees lack the necessary knowledge for disaster prevention, self-help and mutual aid. Thus, the primary and secondary digital disaster emergency education is the necessary way to solve practical problems. It encourages schools to pay much attention to the digital disaster emergency education and enable students to understand the national disaster status. Ultimately, the educational outcomes should satisfy the practical needs and reach the effect of disaster prevention and mitigation.

Based on the characteristics of physical and mental development of primary and secondary students, we can know that this stage of their growth is with high plasticity and great volatility, and their future thinking and behavior patterns more depends on the shape of this period, this growth period has an essential impact on the development of their whole life. Education is to last for generations. Since primary and secondary students are the future of the country, we must pay attention to their education. Digital disaster emergency education is an essential part of education, and it should not be ignored.

Effective Digital Disaster Education enable us to recognize the reason, law and countermeasures of disasters, it can help to alleviate the extent of human losses brought by the disasters, and it fully mobilize the people's consciousness and passion to understand the nature and society and optimize the living environment. Schools are the specialized agencies engaged in educational activities, they are the main bearer of knowledge. Therefore, we must attach great importance to the school Digital Disaster Education, especially Digital Disaster Education in primary and secondary schools. To carry out Digital Disaster Education among primary and secondary students can help them to deepen their understanding of disasters. They represent the future of our country, and their disaster literacy to a certain extent determines the rise and fall of the nation and the state. At the same time, Digital Disaster Education is the important part of the quality education in schools, it can effectively improve the students' knowledge and ability to prevent disaster, and it can also improve the sense of crisis and awareness of sustainable development as well as their moral feelings.

Digital Disaster Education starts from the people's ethics, it eliminates the unsafe behavior of people in disasters. The aim is to improve people's ideology and the practical ability. Through Digital Disaster Education and training, people can master a certain number and types of disaster information. For this reason, many researchers have studied what the Digital Disaster Education should contain and propose their respective insights from multiple perspectives. These provide valuable advices to schools for Digital Disaster Education.

From the purpose of Digital Disaster Education, it is not difficult to think that the contents of the most basic of Digital Disaster Education should include disaster-related knowledge, awareness, capacity and skills. Knowledge is not only the basis of awareness creation, but also the prerequisite for a good disaster emergency response capability.Of course, every researcher has a different opinion. The author believes that Digital Disaster Education consists of knowledge teaching, practical exercises and other aspects from the macro level. Thus, the core contents of primary and secondary Digital Disaster Education first should include the following aspects: primary and secondary disaster emergency knowledge education, primary and secondary disaster awareness education, primary and secondary disaster emergency capability education, primary and secondary disaster emergency psychology education, primary and secondary disaster ethics education, primary and secondary environment protection education.

A Survey on the Remedy for the Present Secondary and Primary Schools

We prepare totally 30 questions for the secondary and primary students. This questionnaire tests the basic understanding on the knowledge towards the problem, to examine on their capability of survive towards the problem, their awareness on the problem on daily life, and the schools' response on dealing with the problem. The questionnaire for secondary and primary students on their remedy towards the problem.

The 114 effective questionnaires, 80.5% think they are closely related, 3.5% think they are not related and 15.9% of them are not sure. From the statistics, most of the students can realized the natural disaster is closely related to human behavior, just a small percentage of them hold the opposite view. There are still a certain percentage of students who do not have the above concept. This warns us that education have to be improved with the relationship between natural disaster and human behavior, leading the students realizing the hidden disaster in their daily life.

88.5% of the students choose A. this shows the students' tendency on knowing more about the disaster. 0.9% chooses B and C, and even a small percentage of the students think that it is fine unless it does not affect their academic. Students who choose this may be affected by the

examination-oriented education, where examination is necessary and important in study where knowing more about disasters is complementary. Enlightening these students can impress them with the significance and the urgency on acquainting with the disaster. Predominating over the technique on remedy for the disaster can make sure people will not get sucks when they face the disasters.

Emergency readiness is a key experience to the awareness on disaster emergency. It will be easier to handle the disaster when you have the awareness on how to deal with it in advance. From the above table, more than half of the participants have a little preparation, 17.7% of them are ready while 15.8% are quite ready, and even 14.2% are not ready. This shows that secondary and primary students have a low degree in their intention on the remedy of the disaster. This reflects the awareness on getting ready for the disaster is not high. Moreover, it is warning the methods of education and the educational administrators to emphasis on this aspect. The focuses of the schools arouse the students' interest to think about it. This can successfully strengthen students' awareness.

This survey is from the aspect of students' initiative on the information about the disaster. Whether the students pay attention to the study and the information about the prevention of the disaster reflects students' standard in the study of it. The multiple choice question shows the students' cognition is not enough, 75.3% of them will seldom realize and only 16.8% always realize and even 9.7% of them never realize. How can students' initiative towards the disaster be improved? This is the problem faced by the educators.

Understanding of the shelter nearby can directly improve the capacity and effectiveness of emergency refuge, but also a reflection of the awareness. When a person initiatory understands the refuge areas, this awareness has risen to a certain level. Certainly, this consciousness is the result of a combination of daily life and social education, family education, school. The table shows that the vast majority of people do not know the shelter in their area where only 34.5% of people know.

This survey is on learning the need for disaster prevention knowledge. The result shows the problem is still relatively optimistic, 88.5 percent of the students feel the need and those who think it is unnecessary only occupies 4.4%, 7.1% of them say they don't know and this either relates to their contact in this respect knowledge, or they don't know much about the time of the disaster, or they lack of the understanding of disaster prevention-related knowledge.

Publicity and educational content to the image, radio, print materials on disaster prevention and mitigation will arouse people's interest to them. 32.7% of them will pay attention to them and look forward to learn some skills, and their respective 8% of people do not look or do not care, watching from afar. Primary and secondary schools still plays a emotional thinking predominant role in the development stage, so they usually pay attention to what they are interested in, so the publicity disaster education time should be used in a proper manner which made the educational content colorful to attract students, as well as enhancing the publicity and the effect of promoting education. This can greatly improve the education quality and efficiency of knowledge towards disasters

From the survey, more than one-fifth of the household have first aid supplies, a third of them have some, 17.7% of people do not know whether they have first aid supplies, 26.5% do not have first aid supplies at home. This reflects the level of preparedness of the emergency first aid supplies of the primary and secondary household is not high. A considerable part of primary and secondary students are not familiar with first aid supplies at home.

This question is to check the students' understanding of the disaster, the debris flow of the original forest should be considered as natural disasters. The result of the survey showed that 51.8% of the students consider it as natural disaster, 36.3 % choose uncertainty, and the remaining 11.5% of people do not think it is. This reflects more students do not have a deep understanding about the natural disasters.

Summary

With the frequent occurrence of disasters in China in recent years, as well as in the face of risk of severe losses, it is generally able to recognize the importance of disaster emergency knowledge. Although the primary and secondary school students, teachers, educational administrators consciously agree with the need for disaster emergency response education, recognition of disaster emergency power of knowledge. However, this awareness of putting it into practice has not translated into guidelines for action.

Weighing theory heavier than practice is the common problem of China's traditional education. Digital disaster emergency education is no exception. Survey found that students, teachers or administrators, share their response on the school digital disaster emergency education and re-known light training. Schools are more or less involved in the learning of the disaster-related emergency knowledge, but very little or almost no drill, resulting in the knowledge learned cannot be applied. They do not know how to use the emergency equipment available. The result is the study of knowledge does not translate into the ability, whether school teachers or students. Disaster emergency response capacity, as well as disaster literacy, has always been high.

Passive digital disaster emergency education are what teachers granted students. Teachers are passively follow instructions in accordance with the requirements of the school leadership education for students, and school administrators need to convey a higher level of notice. All these coupled with heavy education theory and practice of light. The entire process, in addition to going through the motions of the traditional core guidelines, are for giving and receiving knowledge, without any generated nor an innovative and forward-thinking leadership to schools in line with local conditions and individual condition. Combined with the point of national policy, the educational resources of the region are fully exploited to join forces to make the school digital disaster emergency education really play effectiveness, causing the digital disaster emergency education of the school to close in.

Organizational disaster drill or developing Digital Disaster Education resources, it is not only the matter of time or manpower, but the certain of financial capital. Practise need places, drill equipment. Supplies are needed to purchase, but require more development resources technical needs financial support. Primary and secondary schools, especially schools of remote areas, are having funding difficulties. Thus, they can only eliminate the need for this project, or in a simple way. This is why many schools found it difficult to implement the education needs of disaster emergency.

Fashion Design Professional Basis Based on Design Process

Guo Tao[1, a]

[1]School of Mathematics and Science, Shijiazhuang University of Economics, Shijiazhuang 050031, China

[a]sjzueguotao@163.com

Keywords: Fashion Design, Design Process, Professional Basis

Abstract. In the process of fashion design, design process is very important, and it can be implemented by the computer assistant design software using the 2D&3D modeling technique. Virtual fashion design and simulation involves a combination of a large range of techniques, involving mechanical simulation, collision detection, and user interface techniques for creating garments. In this paper, we study the computer assistant fashion design based on the 2D&3D modeling technique by the design process. We perform an extensive review of the fashion design and its design process, and studied computer assistant fashion design based on the 2D&3D modeling technique.

Introduction

Fashion design is the art of the application of design and aesthetics or natural beauty to clothing and accessories. Fashion design is influenced by cultural and social latitudes, and has varied over time and place. Fashion designers work in a number of ways in designing clothing and accessories. Some work alone or as part of a team. They attempt to satisfy consumer desire for aesthetically designed clothing; and, because of the time required to bring a garment onto the market, must at times anticipate changing consumer tastes.

Computer Assistant Fashion Design

The garment industry is still attached to the traditional way of designing garments, which is based on designing patterns (shapes of fabric) which are then seamed together on a mannequin. While CAD tools (Lectra, Gerber, Investronica) are now highly involved in the 2D design process of the patterns, the actual prototyping is still performed using real cloth pieces and mannequins. Some attempts were made to bring this validation phase in the virtual world as well, using cloth simulation techniques. This approach is still quite inefficient because of the lack of integration between the 2D pattern design process and the 3D simulation. Interactivity between design and simulation is the key idea for solving this bottleneck. While current systems require the re-assembly and draping of the garment over the body for any design change on the garment patterns, we propose a new approach offer a smart integration of the 2D pattern shape editor along with the 3D garment shape view to assess interactively the effect of any pattern shape edit or posture and measurement change on the mannequin.

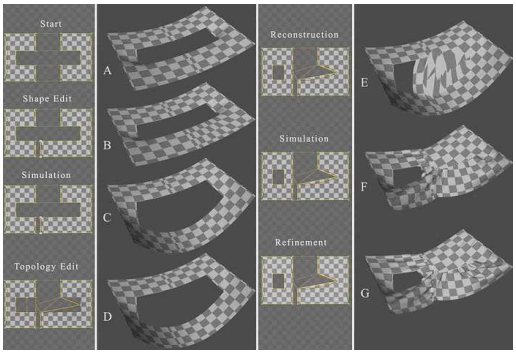

Figure 1. Interactive garment design: from an initial draped pattern (A), editing the 2D contour of a pattern while keeping its 3D shape constant (B) allows mechanical simulation to smoothly drape the pattern to its new 3D shape (C). If pattern editing involves topology or seaming changes (D), the pattern surface is automatically reconstructed in the same position (E) using interpolation if necessary, and simulation performs the draping (F). The surface may be refined at any time (G) for more accuracy.

2.1. Interactive design of patterns

Using patterns imported from industry CAD tools, the proposed framework obviously addresses the issues of placing the patterns around a mannequin, seaming the patterns together, and performing the draping using mechanical simulation. However, the main interest of the framework is rather related to the possibility of refining and altering the design of the patterns in real-time, with interactive preview of the effects on the garment draped on the mannequin. These edit possibilities include resizing, reshaping, adding darts, holes, seams, pleats, attachments (zips, buttons), changing the fabric material (mechanical properties and texture). The mannequin can be interactively changed as well, both for measurements and for postures and motion sequences.

The system reacts immediately to these changes by updating the draped garment interactively. The new garment shape is automatically recomputed using accurate mechanical properties in order to exhibit the features that have been altered by the edits. Geometrical accuracy of the simulation may be changed at any time to provide the optimal compromise between accuracy and interactivity at any stage of the design process. Advanced visualization tools can also display at any time the local mechanical properties of cloth (mechanical deformations, contact forces) for a good evaluation of the fitting and the comfortability, for any chosen size and posture of the mannequin which can also be customized (measurements, posture and appearance) and animated interactively.

Using an innovative design tool for garment design and simulation (in Figure 1), we intend to bring new advances not only in the field of garment simulation for computer graphics characters, but also as a valuable design and prototyping tool for the actual needs of the garment industry.

2.2. The mechanical model

This mechanical model is based on an accurate representation of the surface deformation of a triangular surface element equivalent to a first-order finite element description. Weft, warp and shear deformation and deformation speed are accurately measured on each element and translated into forces using the strain-stress curves defined by the mechanical properties. These forces are then propagated onto the mesh vertices, and any kind of integration scheme traditionally used for particle systems may then be used. Bending viscoelasticity is modeled as forces between adjacent mesh elements derived from the bending measured between them.

At the crossroad of particle systems and first-order finite elements, this model offers a very good compromise between speed and accuracy. Weft, warp, shear and Poisson viscoelasticity behavior is accurately represented by this scheme and, unlike representations based on spring-mass models, and the accuracy is quite well maintained with large deformations.

Another benefit of this model is that it does not rely on regular particle arrays, but satisfies itself from any triangle mesh for describing the cloth surface. This allows complete freedom in the design of the pattern shape, as well as optimal surface representations using adapted or dynamic local mesh refinements.

2.3. Collision detection and response

While much emphasis is put the efficiency and accuracy of the mechanical simulation, processing the collisions which occur between the cloth and the body, as well as between two different parts of the cloth, remains a compulsory issue to address efficiently. This problem relates both to detection (how to find out efficiently the geometrical contacts between complex moving surfaces) and response (how these geometric contacts alter the mechanical behavior of the cloth realistically, and how this integrates efficiently to the simulation scheme). The main issue is to master the complexity of the problem due to the discretization. The cloth surface, as well as the body surface, are represented by polygonal meshes that can have several thousands polygons each. Testing each couple of polygons for potential collisions is an unrealistic task. Many optimized algorithms have been developed for that purpose, either based on space subdivision or hierarchisation (voxelisation, octree), object hierarchisation (volume-box hierarchies), spatial projection and ordering. As soon as the distance separating two objects is small enough to consider that they are interacting, a 'feedback' should be performed on their behavior. Collision response aims to reproduce this interaction in an accurate way, primarily to avoid unrealistic interpenetration of the objects, and secondary to simulate realistic bouncing and friction effects.

2.4. Simulation of dynamic meshes

An interactive design framework obviously needs efficient mechanical simulation and collision techniques for animating mechanical objects quickly enough for an immediate feedback of the design actions. However, user interaction will only be useful if an adequate management of the pattern design give immediate feedback of the changes to the mechanical simulation system.

The key idea of the system is to take advantage of a dynamically constructed mesh that automatically adapts to the shape and feature changes of the garment patterns during their design. Hence, any action altering the 2D shape of the patterns would have a direct mechanical effect on the 3D shape of the garment surface.

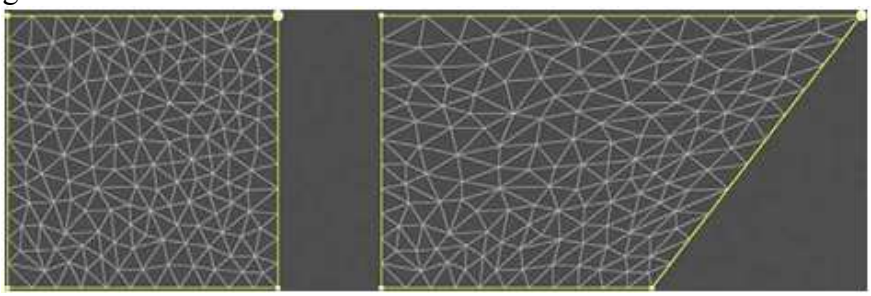

Figure 2. Interactive edition of patterns: each mesh vertex of the pattern surface is displaced by a weighted amount of the displacement of the pattern contour point.

2.5. Real-time animation of garments

The real-time animation has been integrated to the garment design tool to provide a preview of the clothes. Given an animated body and a garment whose rest shape has been computed with the garment design tool, this module provides the real-time visualization of the garments on the animated body. This module can be used at any time during the making of the clothes helping the designers to judge the quality of their clothes. Simulating garments in real-time requires drastic simplifications of the simulation process to be carried out, possibly at the expense of mechanical and geometrical accuracy. Our approach is based on a hybrid method where the cloth is segmented into various sections where different algorithms are applied. When observing a garment worn on a moving character, we notice that the movement of the garment can be classified into several categories depending on how the garment is laid on, whether it sticks to, or flows on, the body surface. For instance, a tight pair of trousers will mainly follow the movement of the legs, whilst a skirt will flow around the legs.

Conclusion

In the process of fashion design, design process is very important, and it can be implemented by the computer assistant design software using the 2D&3D modeling technique.

However, virtual prototyping still cannot pretend being a complete substitution to manual prototyping for a matter of accuracy, and it nevertheless allows speeding up the design cycle of garments by allowing the garment designer to address quickly the issues related to draping and fitting. Computer assistant fashion design can enhance these features by drastically shortening the cycle between pattern edition and visualization of the changes on the garment, skipping the process of reconstruction of new virtual garment models for each step of the design, and the measurements and the posture of the mannequin can also be changed interactively.

Keywords: Higher Education; PE Teaching; Computer Supplementary Software; Development and Application Research

Abstract. Based on the scientific design, development, application, evaluation and management of study processes and teaching resources in PE teaching in higher education, centered by the educational ideas of human centered and health first, this study explored the development and application of computer supplementary software of CAI, CAT, CMI in PE teaching, widened the new study channel of students! development and research study mode, cultivate students! Creativity and practical ability, improve thoroughly students basic sport knowledge, basic techniques, physical fitness and the level of health, therefore enhance the modernization of PE teaching, measurement, educational management methods in PE teaching of higher education.

Introduction

Exploring the development and application of computer aided software in the sports teaching is of very important practical significance in broadening the channels of learning, improve the quality of physical education, cultivating the students' innovation spirit and practice ability, promoting the scientific and modernized level of teaching management in college physical education, physical curriculum test and teaching management.

Research objects and methods

Guided under the modern education technology theory, this paper took the software applying in the physical education teaching in colleges and universities such as CAI, CAT and CMI as the research object. By using the methods of literature review, software and its application and statistical analysis, this paper tried to explore the universities sports teaching (or learning) process, teaching (or learning) resources' design, development, utilization, evaluation and the rules and characteristics of management.

The results and analysis

Results

Software of Sports Online Course Selection System

By combing the Dream weaver MX web software and Microsoft ASP.NET technology with the reality of sports teaching in colleges and universities, the software of sports online course selection system was developed independently.

Through the sports online course selection system, students can get the teachers' basic information and their relative curriculum. At same time, students can also query the questions through an online real-time problems solving between teachers and students to avoid the passive or blindly curriculum choosing. Students can get much more detailed and more comprehensive understanding of the teachers, much more deep understand of sports and more information on the relative course such as opening weeks of the course, teaching plan, teaching content and etc. In this

case, the problem for students how to choose their favorite sports curriculum can be solved. Furthermore, teachers can also use "sports online course selection system" software to get a comprehensive understanding on the information of their courses choosing including the number of students and their basic information timely in order to improve their sports teaching.

Sports courseware

By using Macromedia Authorware and combing with the Flash and Poser, a variety of sports teaching courseware have been developed. In the process of developing the sports teaching courseware, the aim of the courseware is always insisted to translate the teacher's demonstration tools into the students' cognitive tools, the transition from the traditional teaching process logic analysis to the process of students to discover problems, explore the problems. By using the sports courseware, the students' sports skills and their ability to body health care can be cultivated.

Fabrication of the human animation using Poser The software of Poser provides a rich and colorful human body 3D models for the developing the sports courseware. By using those models, the shape and the movement of the body can be constructed easily and quickly. The human body model provided by the software can be customized a variety of types and posture according to the requirement which can be used in the design of the courseware directly. The exquisite realistic human action produced by the software can be saved for the sports courseware material. The import function of the Poser allows the scene control by the 3Dstudio Max and Light Wave which largely enriched the creation of the human body modeling and motion design. And the Export function of the Poser allows characters designed to convert into other 3D design software. The Export function can also make it work with the Flash software and the output into 2 d Flash animation which can be exported through Viewpoint Media Player to realize three dimensional animation of human body model demonstration on the Internet.

Sports teaching technology animation developed using Flash Flash software is one of the most popular animation software. By using this software, the human body model developed by Poser can be exported and deal wit photoshop software to produce colorful human body movement which can be exported again into Flash to demonstrate very lifelike technique movement by setting key frames of movement.

Development of synthetic sports teaching courseware using Macromedia Author ware Although there are many tools can edit synthetic sports courseware, the best interactive sports courseware developed tools is still Macromedia Authorware. It not only can synthesize human technique movement produced by a variety of software, but also can utilize the word, voice, picture, video and animation edited by using other software. In this case, the interaction between teachers and students can be realized in physical education teaching.

Finally, the sports teaching courseware suitable for colleges and universities characteristic can be developed. This courseware should be used on trial in the teaching both for teachers and students after its preliminary revision completed to test whether the courseware is suitable for. Through their using, the modification can be made based on their suggestions for revision, and at same time, the teachers with rich experience can be invited to make evaluation on the courseware and the further revision can then be completed. After full consideration, the courseware can be packaged and burned into a CD to make it directly run on the other computer.

Sports online examination system

During the process of sports teaching, the summative evaluation and formative evaluation are always paid much more attention of the teaching process. At same time, the main measurement of physical education teaching quality monitoring is developed by taking the codes as the reference for the quantitative measurement and comparison. the sports online examination system can achieve interactive tests, assignments and exams, automatic statistics scores.

Sports teaching evaluation system

The correct and fair evaluation of teachers' teaching level and teaching ability is the guarantee of improving teaching quality. According to the practical situation of sports teaching in colleges and universities, five aspects such as preparation before class, teachers' basic skills, teaching contents, teaching methods and ability cultivation are adopted for the comprehensive evaluation of teachers.

Based on this, by adopting the method of mathematical statistics and combining with the web page creation software Dreamweaver MX and Microsoft ASP. NET technologies, the evaluation content are produced into an interactive web pages. The system calculate automatically the teaching evaluation level of average score based on the teachers online self and mutual evaluation, student evaluation according to each item A, B, C, D.

Sports teaching integrated management system

By using Visual FoxPro6.0 database, the development of the sports integrated management system software can realize the assessment of school physical education teachers and the management of the teaching file and teaching materials, students, standard test of student physique healthy, extracurricular sports activities, extracurricular sports training, sports competition, sports funds, sports venues and equipment, sports information and etc, which making the school sports management and sports teaching scientific and standardized. Besides this, the quality of physical education teaching depends on the processing capability of all kinds of information which is also the sign of a school sports teaching management level. This sports integrated management system software can handle well the teaching file and teaching equipment in physical education teaching, student achievement, ability of teacher's professional level of data. Furthermore, based on these data, the software can finish the comprehensive statistics, analysis and evaluation of various data.

Analysis

Computer aided software development

Based on the general law of sports teaching including the preparation before class, the process of physical teaching, summary after class, the management system meeting the demand of physical education teaching and testing are designed by using the survey method to collect the basic information of students need and with scientific data analysis.

To deal with the problem in the process of teaching and learning, the computer aided software are designed and developed including the clarify of content analysis, object analysis, specific goals, strategies, design, media selection and production, etc. by applying the modern education theory and technology. After trial using, Modification are made on the basis of formative assessment and the teaching effect. After all, the summative evaluation are made based on the actual situation of teaching.

Establishment of the ASP technology and database

By using Web page creation and ASP technology, the sports online course selection system, the sports online examination system and the sports teaching integrated management system are developed. The detail process are as follows:

At first, a new folder is created with a name. Then open the Access or Visual Fox Pro6. 0 database software to create a new database db1 and set up two tables. The relationship field between the two tables and table field is category name. After that, open the Dreamweaver MX web page for a new web page and choose the Dynamic page and Asp VBScript to expand the Application panel to enter the ODBC Data Source manager. Finally, a home page is established which can link the student id link to the database .ASP.

CAI analysis

Based on the knowledge of computer operation and good command of software, such as image processing software (photoshop, coreldraw and freehand), voice processing software (Ulead media studio, sound forge, cool edit, wave edit), animation processing software (Auto Desk Animator Pro, 3DS MAX, Maya and Flash) and other common courseware developing software (PowerPoint, Author ware, Director, Tool Book and Flash), the physical teachers can develop teaching courseware suitable for college physical education by integrating the collective wisdom and studying diligently the teaching material, teaching methods, carefully designed and writing scripts.

CAT analysis

Currently, the application of CAT in the sports teaching is realized mainly through operation of the background database by using ASP, Php technology to make modification in time and reflect those modifications on the user's browser side to realize the dynamic and personalized online sports

computer aided teaching test page. Through internet, students can input sports terminology and basic concepts of hot word to complete query and browse the relative knowledge point including difficult point and important point. Besides this, students can get the knowledge through the instance analysis, problem analysis and recommendations to master the knowledge and skills needed on the internet.

CMT analysis

CMT is applied to the university sports teaching management to relive the heavy burden of PE teachers on the student performance statistics and attendance statistics. It can print all kinds of report conveniently. With CMT, student's sports qualified standard statistical elements including physical education, the year total score, national physical exercise standard scores and grades and morning fuck action classes course of absenteeism can be provided easily. And the sports qualified standard form can be filled very conveniently.

Conclusions and suggestions

Conclusions

The development and application of CAI in sports teaching. This application can stimulate students interest in learning to mobilize the enthusiasm of students' active participation and expand students' knowledge and can provide students with a variety of learning sports basic knowledge, basic technology and skills.

The application of CAT in physical education teaching can improve the efficiency in a series of links such as storage, test paper generation, implementation, testing, scoring, the results of statistical analysis and score query. All this can relive the labor burden on the teachers and education administrators.

CMI application in physical education can improve the management level of physical education and improve the efficiency of sports teaching and the degree of specification to a large extent.

Suggestions

The computer and network hardware and technical support should be strengthened.

The teaching practice innovation and theory research of computer aided sports should be improved.

the application and development of CAI, the CAT and the CMI software in sports teaching should be broadened.

The ability of teachers developing the CAI, the CAT and the CMI software should be improved.

Keywords: information technology; construction principles; multimedia classroom; micro-classrooms; teaching environment integration, Educational Technology

Abstract. By using the Information Technology, the paper sets out to start a systematical design and exploration of micro-teaching and E-learning resources adopted in a public experiment teaching course named "Educational Technology" in some advanced normal universities. Besides, by examining the constructive principles of the experimental teaching environment, it has transformed the single experiment learning model which took place in traditional classes, improved the teaching efficiency and quality. And lastly, it discusses such items as learning resources on the internet, the integration of multimedia and micro-teaching as well as the micro-grid classroom construction principles, and puts forward the present college media environment building program, which meanwhile promotes the integration between technology and curriculum.

Multimedia teaching involves texts, graphics, animation, video, sound, special effects, and also includes unlimited imagination. It not only changed the way we learn and the method to solve problems, but also changed the way through which information is spread. It is a technique combining many subjects such as computer graphics, image processing, video art, music, fine arts, education, psychology, artificial intelligence, information science and electronic science and one that brings words, graphics, images, sound, video images, 2-D and 3-D animation together, which fully mobilize the visual and auditory processing.

Microteaching is actually a practice environment that enables everyday classroom teaching to become simple by decomposing it, which, at the same time, will help the learners get lots of feedback. Being a controlled practicing system, it makes normal students or in-service teachers focus on certain teaching behaviors and learn under controlled conditions. It is also a method of training teachers which bases on the teaching theory, visual theory as well as technology.

The principles of constructing multimedia and micro-teaching environment

1. A multimedia classroom construction principle

(1) Utility, which is the main goal of building an effective classroom, because the highest profits can only be guaranteed by the best effects. It is easy and free enough to operate for learners of different majors.

(2) Reliability. Reliability is the first principle when thinking about constructing a program, because human safety, machine reliability and long-term stable operation of the equipment will ensure that the users are provided with the relevant guidance when the system is under processing, which will help to reduce the cost of labor and capital during the operational process.

(3) Compatibility. The device has similar equipment compatibility with different manufacturers and different models.

(4) Advancement. The selection of equipment, especially the central control software must adapt to the direction of technological development, and fully reflect the advancement of the entire system.

(5) Expansibility. A primary principle for a multimedia classroom is whether it can be associated with Internet and whether it can call the outdoor classroom teaching resources.

(6) Security. Considering the security of multi-media classrooms during the non-instructional time, the console should be customized according to equipment specifications and take into account the factors such as security and fire.

(7) Convenience. The device makes it easier for teachers to operate the device by getting rid of the process of switching the equipment in and after class. That is, the power will be cut off with a remote control or by locking the device.

(8) Economy. System design and equipment selection should focus on the practical function, aim at reducing the overall investment, and seek a perfect unity between advancement and economy. In term of this, we should consider the actual demand of school teaching management and try to get rid of all that are not needed.

2. The micro-classroom construction principle.

(1) Being easy to control. The micro-teaching system is an intelligent and digital system and it should be designed to meet the authenticity, validity and convenience principle. Being easy to control helps to satisfy the needs of teaching, and simplify the process in which students as well as teachers are trying to improve their teaching skills.

(2) Scientific. The construction of intelligent micro-teaching system should meet the whole idea of micro-teaching and follow the trainers ' psychological needs. Meanwhile, it should keep in pace with times in the choice of equipment, make scientific predictions of the development trend of micro-teaching, and then manage to achieve it.

(3) Utility. While ensuring the usefulness of teaching and training needs of micro-teaching system construction, one should also consider an appropriate price. According to the Value Analysis, the overall value can be obtained (V) through a functional analysis of its value and the actual value of the investment ratio. In this case, one can make the appropriate analysis based on the engineering analysis for selection.

The constructing of multimedia and micro-teaching environment

1. Multimedia classrooms construction

Multimedia classrooms should be constructed according to the constructive principle, and make a scientific and rational selection of the equipment. In the paper, a multimedia console is designed, and then multimedia classrooms are constructed relatively concentrated according to the discipline needed in the course, which also takes into account their location, shapes, size as well as seats. The construction of the classroom is made up of two parts, i.e., the design of laboratory and the teaching equipment. The teaching system will keep the digital and intelligent development.

(1)The construction of multimedia classrooms under the network managing environment. These classrooms are suitable for the areas where multimedia classrooms are relatively concentrated. And they will be different in function according to the needs of different subjects. The specific equipment program is shown in Table 1.

Table 1 Multimedia classroom network management solutions:

Equipment Name	Amount	Remarks
Multimedia computer	1	Requires a DVD drive P4 2. 6 above configuration
The central control system	1	Network control and management
Projector	1	Configure the projector and screen brightness based on classroom size
Electronic screen writing	1	Not only for writing but also as a computer monitor screen
Console (custom)	1	According to the actual needs of customization, in line with security, safe, aesthetics, practice
Amplifier (lavaliere wireless microphone)	2	Equipped according to PA, have a line input function
Monitoring on-demand system	1	Master the dynamic teaching, play on time when there is a demand.
Intercom System	1	Helpful for real-time communication and solving problems
Multimedia network classroom software		Realize broadcasting, monitoring, voice teaching of teachers to students, help students complete the learning and use of computer software.

The configuration applies the central control system of a network, and the network operator can either use a remote control or a local control, which increases the control system. The correlation function is as following.

(1) Central control system. Network managing multimedia classrooms uses a network central control system, including classroom network control and total control software. The system is highly integrated, rich in interfaces and very powerful. It is embedded with network interface. By using TCP / IP technology, and through the campus network interconnection, a remote centralized control can be achieved. Besides, 3 controlling ways are to be chosen, i.e. network, software and manual control panel. Lastly, it owns the delay function to prevent damage to the equipment when electricity is off.

(2) Console. Similar to the stand-alone multimedia classrooms, the console is also based on rational design to make it easy to use (such as the required teaching device interface installation) and meet the security demand. Console door opening can be controlled remotely through the network, which can be realized through local operation too. In other words, the controlling lock linked with central control system also acts as a console lock. Thus a lock is of great use and convenience lying in that the opening and closing of computers are all controlled by it with the assistance of the Various Linkage System.

(3) Demand monitoring systems. The adoption of the system is better for the managers to master the remote teaching dynamic. The associated control software allows teachers to use the contents on the screen to get the synchronization audio or video records, which could get to instant on-demand and broadcast capabilities through the system.

(4) Intercom systems. The application of intercom system can help to discover and solve problems immediately. Currently intercom is found in different ways, such as duplex, half-duplex intercom systems, telephone intercom systems, IP telephone network methods, etc.

(5) Extensive practical function. This includes screen broadcasting, video broadcasting, voice broadcasting, programme distributing, homework gathering, mass discussion, division sign, and so on.

2. Intelligent micro-classrooms construction

Smart micro-classrooms should be constructed according to the constructing principles, and the equipment selection is designed according to the teaching content. The choice of equipment should also be designed along with the two factors. Similarly, teaching systems should keep the digital and intelligent development. Apart from this, it requires to make scientific predictions to the micro-teaching trends from time to time. Intelligent micro-classrooms teaching include the teaching equipment and laboratory design (shown in table 2).

Table 2 Smart micro classrooms program:

Name of the Equipment	Amount	Remarks
Multimedia computer	1	Responsible for the overall control, management and production of power equipment systems
Microphone, camera	2	Completion of the acquisition for video and audio signals
Video and audio Presenter	1	Depending on the completion of control playback of audio files,
Network File Server	1	Micro-teaching resource library, installed in the control center of the campus network.
Smart micro-grid network classroom software	1	The core of the whole system.
Console (custom)	1	According to the actual needs of customization, in line with security, safe, aesthetics, practical

The configuration applies the central control system of a network, and the network operator can either use a remote control or a local control, which increases the control system. The correlation function is as following.

(1).Video intercom call box. The simulated classroom is equipped with video intercom call boxes, through which the trainer can call the control center via a button on the call box. The camera has visualization functions, so that the control room staff can keep abreast of the different simulation classroom training situations and conduct the timely processing and feedbacks. What's more, video intercom equipment can be installed among classrooms, making communication of different simulation scenarios possible.

(2).Remote control. The intelligent management could finally be achieved as the network administrators can control and manage the relevant device system and data remotely via loading the campus network management system.

(3).Sub-control system. The controlling function of the control chamber, on the one hand, could be achieved through a multimedia computer with controlling function. And it can also decentralize the control functions. For example, one can control the corresponding devices respectively by setting the camera remote control and the audio console. On the other hand, it integrates the device control system and controls by a controlling system. What's more important, it brings the sub-control advantages of micro control equipment systems of previous generations of system and has complementary advantages.

(4) Multicast video play. In terms of video play, smart micro-grid equipment system can effectively control the digital signals, as well as transmit data regularly within the campus network. It can control the time and place of the file to play, which is not only helpful for the same video files spreading to different classrooms, but also for different files spreading to different classrooms by regulating the computer software.

(5) Evaluating lessons. Evaluation function is important in micro-teaching. In addition to record, produce and play the trainers' live training process, it has also the function of giving an objective

evaluation of the training results. Observation and evaluation work can be conducted in the observation rooms. At the same time, comments can be given by sending the relevant reviews through the campus network or by the use of video conference.

(6) Demonstration. Teachers could make a demonstration of the fine courses in the simulated classroom. And the courses, of course, will be broadcast to classrooms installed with a TV or video player via multicast broadcast, which serve as good examples.

(7) System monitoring and scanning. There is dedicated monitoring software in the intelligent multimedia micro-teaching system. It can start to scan the files and data in the entire system, measure the transforming speed as well as efficiency, and the transmission errors are thus effectively controlled.

(8) Remote transmission. The system enables people to transmit the live teaching process to other places through the campus network, and it also has remote teaching management and evaluation functions, makes up for the micro teaching equipment of previous generation where live broadcast was confined in a small areas.

(9) Standby interface. In order to meet the needs of users to upgrade, smart micro-teaching system reserves the stand by interface. Users can optimize and upgrade the system according to actual need.

The Integration of Multimedia and Micro-teaching System.

It changed the unity of the original experimental teaching methods, overcomes the objective limitations of the experimental lessons and equipment. It is a traditional laboratory extension in time and space, which can promote the integrating process of technology and curriculum.

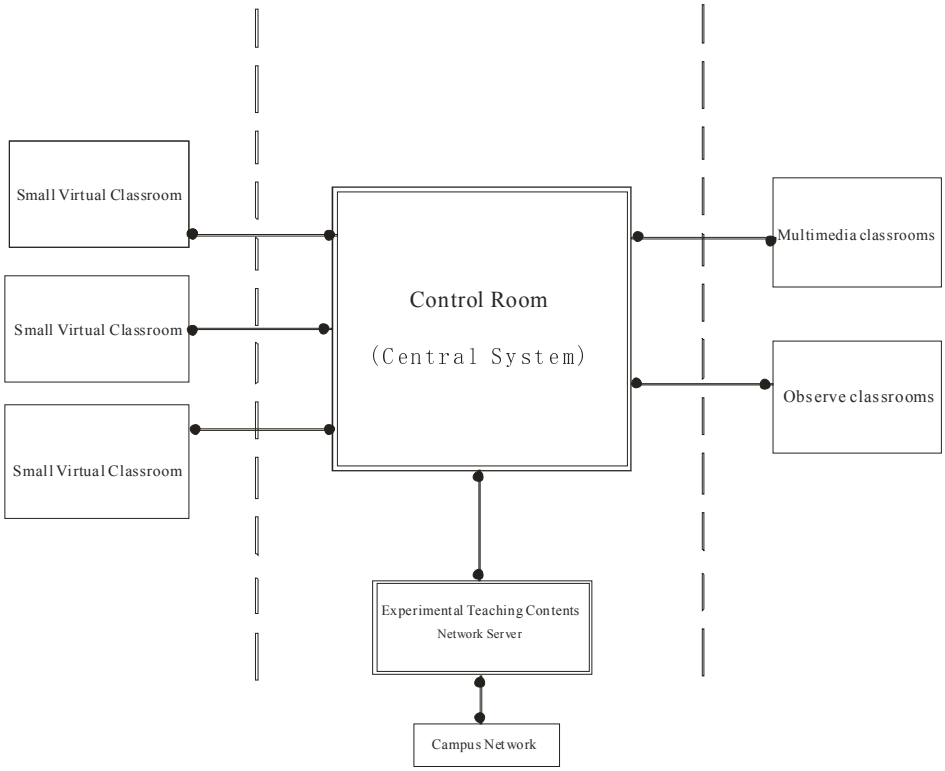
(1) The similarity between multimedia and micro-teaching system by the discussion above, there is a great similarity in the functions of the multimedia and micro-teaching system (shown in Table 3).

Table 3 The similarities in the function of multimedia and micro-teaching system

Similarity	Remarks
Central control system	Includes classroom network control and total control software.
Monitoring on-demand system	Associated control software allows teachers to choose the demanded contents.
Multicast function	transmit data regularly
Network management functions classroom teaching	Corresponding teaching management functions to assist.
Alternate interface functions,	Requires the user to upgrade
Remote transmission function,	Remote teaching management, remote teaching evaluation
Sub-control functions	Integrated control device, the control system controlled by software
Classroom management and maintenance。	Easy maintenance

(2) The design of a micro-media device system

Multimedia and micro-teaching system equipment is the core of the whole system. The overall structural design of the device system is shown in the following FIG.



Media Control Center microteaching

Keywords: Government IT service outsourcing, security and risk management

Abstract. There are potential risks and uncertainties in each phase of IT service outsourcing, which will pose a huge threat on governmental and national security. In order to benefit the outsourcing of government IT service, this paper will study the security and risk management strategies for government IT service outsourcing.

Government IT Service Outsourcing Risk Management

1.1 The Overall Process of Government IT Service Outsourcing

As presented in Fig.1, the overall process of government IT service outsourcing is divided into four stages: planning, acquisition, implementation and termination [1]. In the planning stage, the government needs to analyze needs, conduct market research, develop action plans, and conduct staffing. The primary task of IT service outsourcing acquisition is to choose the right outsourcing service providers. Implementation phase needs to manage the safety, schedule, quality of IT service outsourcing. Termination phase can propose improvements [2] [3] [4].

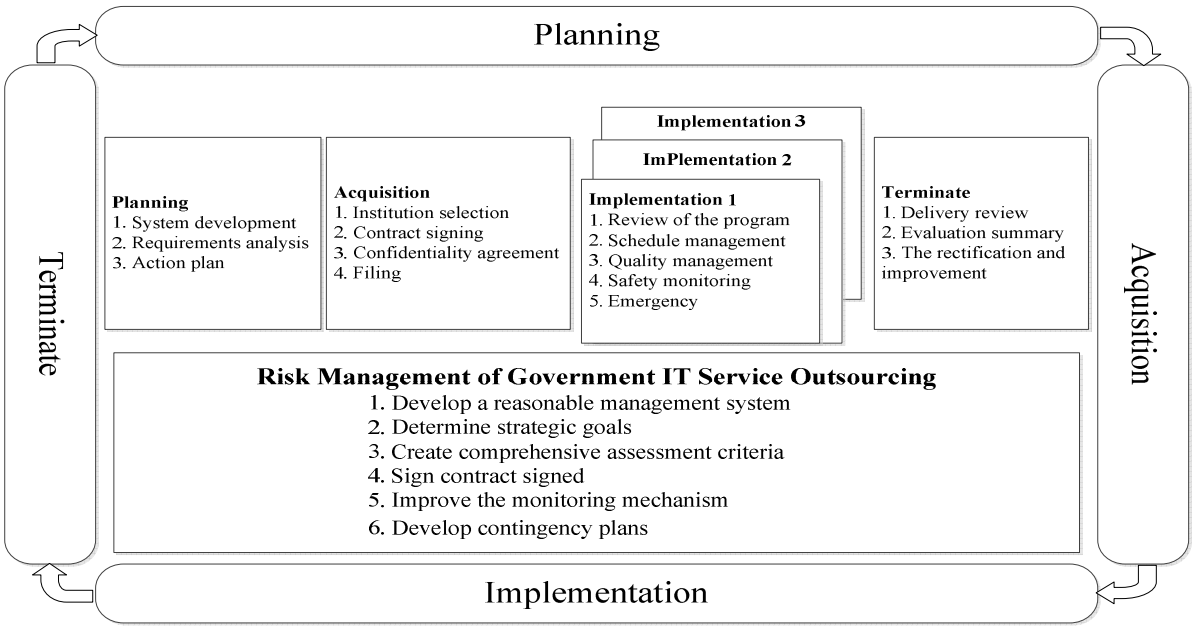

Fig.1. The main frame of IT service outsourcing

1.2 Control Measures Against the Risks of Government IT Service Outsourcing

To address these risks, the government must establish a scientific and reasonable resource management system and develop a sound management system in IT service outsourcing. The government should strictly supervise and manage the entire process of IT service outsourcing, and continue to explore new business development form, and tap new business needs.

Against risks from the government IT service outsourcing, and with reference to China Information Technology Service Standards (ITSS), this paper offers measures which the

government should take in each stage as presented in Fig.2. The followings describe the measures which are specifically addressed these risks in accordance with the order to achieve the IT service outsourcing:

(1) Establish a scientific and rational management system

In the activities of IT service outsourcing, the establishment of rational resource management system is very important, it directly determines the success and safety of the entire outsource activities [5].

Fig.3 shows the framework of the relationship between government and enterprises in IT service outsourcing. Relevant government organizations and enterprises form an alliance which rely on contractual agreements as a link and provide quality services or products. Its structure is composed of three levels: the business layer, management and coordination layer, and outsourcing enterprise level. Among them, the management and coordination layer is composed by three expert groups: development strategy group, Legal Unit and implementation monitoring group, or other departmental structure which perform similar functions. Table 1 gives the detailed composition of the expert group and the various business functions.

(2) Define a clear strategic objective and determine the technical requirements.

With the help of development strategy group, the governmental organizations which intend to implement IT service outsourcing need to plan the development of information systems and information technology, study and explore the technology needs, determine to implement the technological development programs. Generally includes four aspects:

(a) Understand and seek new approaches and channels to apply IT in government business applications and explore new opportunities for the development of government information systems;

(b) Find the existing and ongoing information technology, the actual needs of government business, the gap between the current status of IT application and development objectives. Then survey the needs of application department and decide which projects will be outsourced and which projects need to wait. At last, determine the specific program of IT application;

(c) Evaluate the new developed and popular information technology, forecast the development prospects of the application of new technologies in the government, develop IT development strategy planning and implementation strategies for governmental organizations; and

(d) Collect, classify and analysis the IT development.

The development strategy group should draft scientific information systems development strategy, and determine the proper technical requirements. It should not blindly pursue new technologies to avoid the unnecessary risks of information technology applications, or the excessive financial burden.

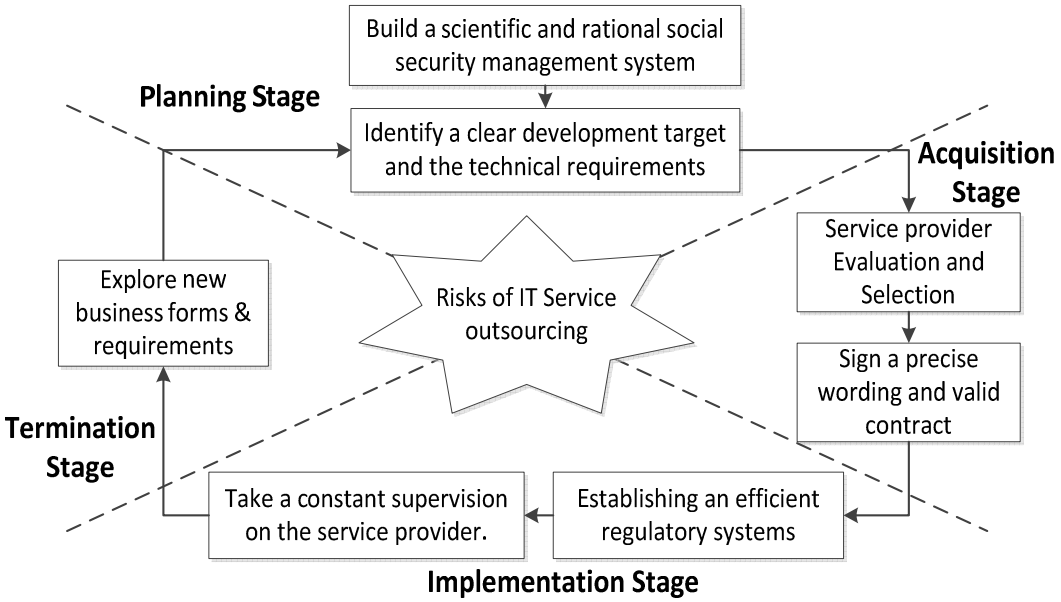

Fig.2 Countermeasures against risks of government IT service outsourcing

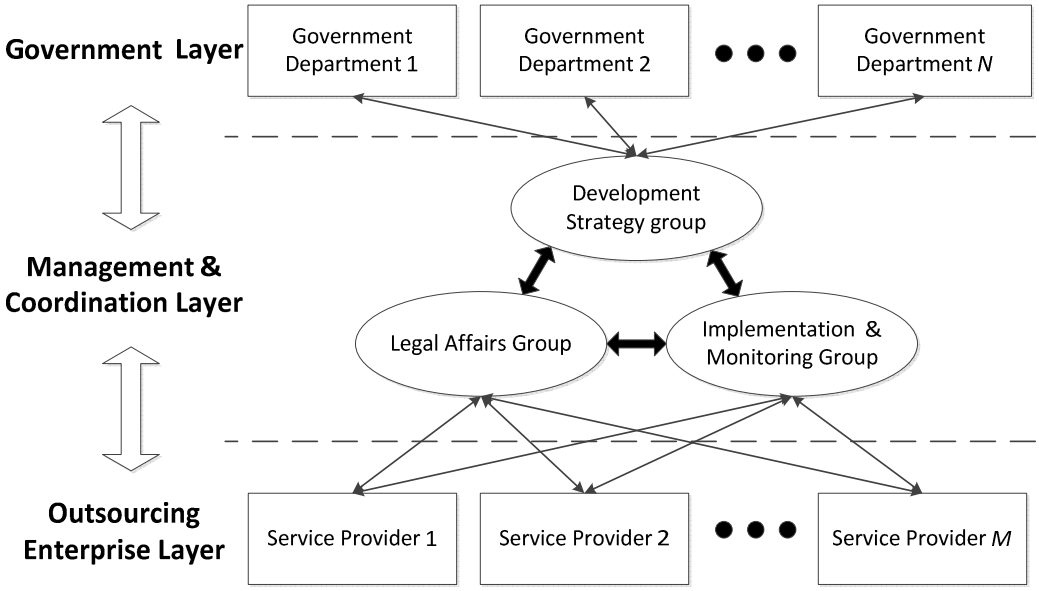

Fig.3 The framework of the relationship between government and enterprises

Tab.1 The detailed composition of the expert group

	Staffs	Functions
Development Strategy Group (DSG, Leaded by the senior fellow of the government)	1.Representatives of the government business department. 2. Experts on information technology; 3. IT outsourcing consulting company; 4. Experts on industry strategy planning.	1. Explore applications of the new information technologies in government IT system. 2. Planning and implementing IT strategy; 3. Explore the requirement of the IT departments, and determine the requirement level; 4. IT application evaluation, determine outsourcing project, implementation scheme, service provider selection etc. 5. Information collection and feedback.
Legal Affairs Group (LAG, Leaded by the Representatives of the DSG)	1.Representatives of DSG; 2. Representatives of IMG; 3. Legal experts on information technology.	1. Negotiation and signing IT outsourcing contracts & agreements; 2. Assisting IMG in resolving the disputes during implementation, and dealing with the corresponding legal affairs; 3. Information collection and feedback etc.
Implementation and Monitoring Group (IMG, Leaded by the delegate of the DSG)	1. IT professionals; 2. Staffs of contracts and agreements management; 3. Coordinators.	1. Reconcile the disputes between government departments and service providers, and the disputes between the service provider; 2 Monitoring the process of the project and participate in project acceptance; 3. Collect materials for possible legal cases; 4. Information collection and feedback etc.

(3) Comprehensively assess and select the service providers.

After the development strategy group study and explore the technology needs of government business sector, they need to evaluate the service providers to determine if their financial and operational capacity can meet needs or not. It mainly includes the following three aspects.

(a) Assess professional skills of service providers and capabilities of professionals.

(b) Assess the level of service provider's understanding of relevant laws and regulations, as well as outsourcing professional knowledge.

(c) Investigate the financial condition and credit worthiness.

(4) Sign a stringent and effective outsourcing contract.

(a) Set a clear outsourcing service boundary and a flexible agreement contract.

(b) Give a reasonable description of service level and measurement.

(c) Build clear liability and dispute settlement procedures.

(d) Limit cost increment and define the right to terminate the contract.

(5) Develop a sound regulatory system

(a) Information security management system. It includes the required information application process in the implementation of the project and authorization method for secret information, to ensure that these measures conduct comprehensive protection for government information confidentiality, integrity and effectiveness.

(b) Business management system. The system includes the specific approaches for government departments to carry out the progress management, to exchange and communicate between the government and service providers or among the service providers, as well as to assess the service quality of the service providers.

(c) Resource management system. The system should guarantee the government resources will not be stolen, misused under the institutional norms.

(6) Conduct strict and constant supervision of service providers.

(7) Explore the new forms of information technology service outsourcing, and tap new business needs.

In addition to taking risk management strategies, and in order to reduce and control the risk of weakening internal learning and innovation, development strategy group should be responsible for exploring new forms of outsourcing. New forms may include partnerships with IT service providers, introducing a shareholding system, to co-invest in new areas of technology and share risks and proceeds. The government shall appoint specific members to research the long-term changes in the business environment, and continue to tap new business needs. The advantages of IT service outsourcing can be fully realized without jeopardizing the internal leaning ability and innovation capacity.

A Spectrum of Findings: Mechanisms for Third-party Evaluation of the Quality on the Application-oriented Undergraduate Teaching

Liang Lei [a], Jun Peng[b*]

College of Electrical and Information Engineering,
Chongqing University of Science and Technology, Chongqing, 401331, China

[a]email: cqlei.l@163.com, [b]email: pengjun70@126.com, *Corresponding author

Keywords: teaching quality; teaching assessment; social evaluation

Abstract. The evaluation on the students' vocational skills and teaching quality is more often unilaterally performed by the school side. The results are not recognized by business, industry and other employers, and further to affect the students' employment rate and quality. This work team carried out a series of research subjects on how to establish a mechanism for third-party evaluation of teaching, where businesses were invited to join the teaching management, with their views on graduates being collected for the initial establishment of an effective evaluation mechanism. This played a very important role in exercising and improving the overall quality of students.

Introduction

Along the universities are undergoing the conversion from elite education to mass education, the mechanism for evaluation on the quality of undergraduate teaching has been explored and gradually become one of the research focus of all universities and enterprises and institutions[1][2].

For teaching quality, an objective and impartial evaluation is an important means to guide teachers on improving their teaching methods and quality. The evaluation on the quality of undergraduate teaching may cover three areas: self-evaluation of teachers, internal evaluation from students, supervisors, university leaders and peers plus the third-party evaluation of any one sector in independent institutions, also known as social evaluation [3].

Teacher's self-evaluation is taken to improve the quality of teaching and promoting the personal development of teachers as the ultimate goal. Meanwhile, the teacher's self-evaluation is largely manifested in the evaluation of students. Currently, most colleges and universities still tend to evaluate the students in the traditional way for general education, which is based on assessment at the end of the semester. Assessment methods are divided into two categories: test and examination. Generally, tests mainly include the written exams, practical operation and usual practice, with attendance as an important indicator to examine student motivation and learning attitude; and examination is mainly based on the usual motivation and learning attitude. These seemingly well-functioning evaluation mechanism actually failed to let the students truly know themselves objectively, nor really inspire the internal driving force from students, much less provide a scientific and rational reference to further enhancement of students. This evaluation method does not recognize the potential that may be found inside students, nor the difference and emphasizes commonality, only counting on the uniform criteria to measure differences in intelligence, behavior, knowledge, background, family environment, hobbies and other aspects of individual students [4]. In addition, the evaluation mechanism cannot play a good role as to improve the quality of teaching.

Internal evaluation given by students, supervisors, college leaders and peers is now widely used in higher education [3]. Student evaluation of teaching quality mainly refers to the teaching evaluation before the end of the course undertaken. The evaluation by supervisors, college leaders and peers are mainly completed through lectures and in the form of questionnaires.

The school side evaluates the students on their professional competence and the teaching quality, where teachers and educational administration act as a major subject. The evaluation on the students' professional competence is mainly implemented through exams organized by schools themselves. Basically, the whole evaluation process is conducted in line with the wishes of the

school, lack of participation and supervision by business, industry and employers, making it difficult to fully consider the requirements by industry for skilled competence and professional quality. This can be a failure to develop a scientific content, criteria and methods for evaluation based on professional competence required for business tasks, resulting in a mere formality throughout the evaluation. The evaluation results are not recognized by businesses, industry and other employers, further to affect the students' employment rate and quality [3].

Focused on this topic, the work team has visited part of the application oriented universities and enterprises located in Shenzhen, Guangzhou, Beijing, Shenyang, Xi'an, Chengdu and Chongqing, also including the visit to University of Michigan. Graduates were given an anonymous questionnaire, where the social assessment served as an important indicator of teaching quality, which played an important role to improve the teaching quality and study atmosphere.

Necessity of Companies Fully Involved in the Evaluation on the Undergraduate Teaching Quality

Business recognition to graduates is the biggest certain for teaching quality. In fact, all along, all colleges and universities in teaching educational administration attach great importance to the evaluation from employers on the quality of teaching. But most college students may wait until the graduates begin to work after graduation, and organize the relevant functional departments or the department personnel to conduct research in enterprises and institutions, carrying out follow-up survey of graduates in the forms of inquiries, questionnaires and seminars to listen the advice from business on the teaching quality of graduates Evaluation of [5]. In this way, views collected on the existing training programs could have a pivotal role in training students. Nonetheless, this sort of assessment is passive with a strong one-sidedness and hysteresis. For this reason, these employers may be part of the planning process and teaching management, and the organizational aspects of teaching, which have a very important significance to improve the quality of teaching.

Companies Fully Involved in Building a Mechanism for the Evaluation on Teaching Quality of Comprehensive Undergraduate

Targeted at the problem that may be present in the system to evaluate the teaching quality, the evaluation of the quality of teaching cannot be limited to the teachers and schools alone as the evaluating subject. Rather, an independent third party with the school should be entrusted for teaching quality evaluation, which is commonly used abroad as a model. That is, industry management experts and technical personnel are combined with institutional experts as a third-party to evaluate the subject, so as to fundamentally raise the level of professional competence of students to improve students' employability and competitiveness [3].

Construction of a third-party evaluation mechanism, the idea is designed based on the "industry-led" concept, according to "***Who***, ***What***, ***How*** and ***What***" regarding evaluation results [3]. In this paper, " ***How*** and ***What*** is the research focus.

Enterprises being part of school teaching management

Making the training plan. When institutions are developing a personnel training plan, enterprises should be invited to participate in the discussion on the adequacy of the social research personnel training program, the accuracy of the market and social positioning, whether the plan is able to meet the future needs of community, whether the implementation plan is in line with corporate standards, whether the personnel evaluation criteria are to meet the enterprise's requirements for job training.

Curriculum setting. Curriculum system is the important support to reflect a personnel training program. Enterprises to participate in the discussion on course content as to whether meeting business needs, whether covering job requirements for knowledge and ability and quality, whether curriculum meets the certification standards of professional engineering education.

Evaluation of the steps of practical training. Enterprises can get involved in the evaluation training segment which should be derived from real projects of enterprises, whether to adopt corporate training methods, whether training course meets the corporate governance norms and standards, whether to be able to achieve the required level of corporate career.

Evaluation of teaching quality. Enterprise is to evaluate whether the content of textbook has an appropriate theory depth and breadth, whether the experimental guide book is modeled on business practices, and whether the forward-looking textbooks are chosen.

Evaluation of the quality of teachers. Enterprises involved in the evaluation of teachers' familiarity on the business process, software development process and development tools, that is, practical ability. Also, the proportion of being "double" teachers and that of enterprises to participate in class are considered.

Enterprise evaluation of graduate students

Enterprise evaluation on the students is designed for graduates with at least three years of working experience, mainly regarding the student's professional and ethical standards, professional attitude, quality and skills and so on. Data collection methods and Enterprise feedback will be described in the section.

Work team has visited the enterprises located in Chongqing, Shenzhen, Guangzhou, Beijing and Shenyang, in the form of questionnaires, feedback from graduates and field survey, collecting a lot of comments from employers on their students. This provides an important basis for us to amend our talent training plan.

Questionnaires. According to the time arrangements by employers, our computer department used the questionnaire to conduct a follow-up survey on the graduates that already had been employed for some time, allowing the employers to give a comprehensive evaluation of the graduates, providing recommendations on our computer professional talent training.

Internships feedback form. Since graduation practice and design sessions are jointly undertaken by companies and universities in teaching tasks, where companies can understand the aspects of the school situation in the computer professional practice teaching. Therefore, an internships feedback system is established. After each end of the internship, the relevant personnel with employers is about to fill an internships feedback proposal form, in order for professional quality evaluation on our computer science teaching.

Field survey. The work team took issues with the personnel training program and visited a number of enterprises, seeking their comments so as to make a training plan to meet the real needs of enterprises.

The work team collected data for analysis, where computer science students are divided into three categories: (a) IT institutions; (b) software development; (c) computer research. And the work team got many enterprise feedbacks.

IT Institutions. Enterprise is focused primarily on students' knowledge and ability in computer networks and hardware, as well as common statistics and analysis capabilities. Common evaluation criteria are shown in Table 1. Evaluation of content includes Attitude, Discipline, Quality, Professionalism, Skills, Teamwork, Innovation, Results, Hardworking, Self-learning, Dedication, Friendliness, Honesty, Impetuous, Respect, Consideration, Complacent, Money Worship, Self-reflection, Communication, Sense of Ownership, Responsibility, Legal Awareness, Hardware Maintenance, Network Maintenance, Office Software, Image Processing.

Software Development. Enterprise is focused primarily on student teamwork and the familiarity with software tools. Common evaluation criteria are shown in Table 1. Evaluation of content includes Attitude, Discipline, Quality, Professionalism, Skills, Teamwork, Innovation, Results, Hardworking, Self-learning, Dedication, Friendliness, Honesty, Impetuous, Respect, Consideration, Complacent, Money Worship, Self-reflection, Communication, Sense of Ownership, Responsibility, Legal Awareness, Algorithm Design, Embedded Programming, Mathematical Foundation, . net or Java, Reading Comprehension, Hardware and , Interface Technology, Data Structure.

Table 1 Assessment by Enterprises on Students

Evaluation of Content	Evaluation Factors	Evaluation Criteria				
		Excellent（90~100）	Good（80~89）	Moderate（70~79）	Qualified（60~69）	Unqualified（0~59）
Test results: A-Excellent B-Good C-Moderate D-Qualified E-Unqualified						

Computer Research. The employers are focused primarily on student math, English and professional theoretical basis. Common evaluation criteria are shown in Table 1. Evaluation of content includes Attitude, Discipline, Quality, Professionalism, Skills, Teamwork, Innovation, Results, Hardworking, Self-learning, Dedication, Friendliness, Honesty, Impetuous, Respect, Consideration, Complacent, Money Worship, Self-reflection, Communication, Sense of Ownership, Responsibility, Legal Awareness, Algorithm Design, English Proficiency, Professional Basis, Programming Capability, Mathematical Foundation, Computer Hardware Foundation.

Different employers may vary on the weight for each of the quality requirements, that is, they may counting on different "evaluation factors". Nevertheless, the above evaluation criteria presents that all employers tend to pay more attention to unity among students, and their innovation, hard-working and self learning abilities.

Conclusion

To establish a third-party evaluation of the quality of teaching mechanisms for application-oriented undergraduates, the work team made a lot field surveys on enterprises and institutions, concluded by establishing a set of methods initially regarding a third party being involved in the community with their teaching management and evaluation of the overall quality of the graduates. This set of mechanisms, when applied to the personnel training mode, has been proven to play a pivotal role in the comprehensive training of our computer science students.

Keywords: Technique teaching in physical education courses ; multimedia CAI technique ; courseware ; design ; application method

Abstract. With the help of modern learning theory, educational media theory, systematic science theory and modern teaching design theory, the mode of making multimedia CAI courseware for technique teaching in physical education courses was designed. Based on this mode, the Multimedia CAI Courseware for Back Layout Teaching has also been made. By application in teaching, a conclusion that there are five advantages of using the Multimedia CAI Courseware for technique teaching in physical education courseware was reached, and three different levels of software and hardware should be prepared for the multimedia CAI courseware teaching. Thus, the three-chain teaching mode for using the multimedia CAI courseware in technique teaching was constructed.

Introduction

As the most notable achievement and human wisdom for education in the 20th century, CAI (Computer Aided Instruction) has become a major part of the educational science and modern educational technology. Meanwhile, it also has become the direction of strategic issue and teaching innovations in scientific research. In this paper, Multimedia CAI Courseware in Back Layout is made and applied in teaching to explore production methods for Technique Teaching in Physical Education Courses with the rules and characteristics of using multimedia CAI technology. The early popularity of multimedia CAI technology in physical education, so as to improve the quality of Physical Education and provide services for training compound sports talents to meet the needs of the 21st century.

Design Process of courseware

Overall Design of Courseware

Making mode of multimedia CAI courseware According to the basic principles of CAI and teaching software development, as with the professional characteristics and the actual situation of courseware development, a mode of CAI courseware that is suitable for Technique Teaching in Physical Education Courses is made.

Teaching target of courseware By the application of courseware in teaching or self-learning process, it can provide a vivid and intuitive learning environment for students. Taking advantage of computer graphics, image, animation, audio, video and other functions, students can develop positive technical concepts and master the project (such as the Back Layout) technology. Besides, they can master mission, action specification, technology essentials and teaching methods of different technical phases in theory with identification, causes analysis and corrective methods of common mistaken actions.

Teaching content of courseware The courseware should be based on the syllabus and the new materials to prepare teaching content. Moreover, it need teachers who work permanently in the front line with extensive experience in the teaching project to check, also a special forum should be held and the courseware content is identified after several revisions.

Teaching media selection and information presented in the form The selection of instructional media is mainly based on the teaching objectives and teaching contents. Because the computer can deal with sound, images, video, text, which makes the choice of media is more

convenient, flexible and economic, but the media must choose the right combination in order to achieve the best effect.

Script Design of Courseware

Manuscript writing Manuscript is a text form of courseware content, which includes all of the text content of designable courseware and can be written separately.

Script card design Script card has a very important role in making courseware. Script card design is mainly based on the content of the manuscript with teaching ideas, teaching strategies, teaching media and forms of information presented designed to each page. It specifically includes text, images, graphics, video, sound, music, and other specific content and forms of presentation. Therefore, script card has a direct impact on the accurate accomplishment of the teaching content, vividness of teaching style and the mix combination of media properly. Script card design is usually done by professionals together with CAI production experts, so that it can ensure CAI experts can better understand the course requirements.

Courseware Making

Structural design of multimedia CAI courseware In order to strengthen interactive learning and convenience of teaching use, courseware usually adopts hypertext (Hypertext) link and every page owns different buttons and hot words.

Multimedia material preparation

Production of text material In the courseware, there are three kinds of commonly used text: 1) ordinary static text; 2) animated text; 3) WordArt. These three words are produced by different software. In summary, the production of text adopts different forms according to different themes and contents.

Image production The image is mainly the pictures, photos and graphics that are used by courseware interface. This section has three main sources: 1) Generating an image file through the scanner, and then use Photoshop and Impactbulm to deal with; 2) For some downloading images, they are put into clipboard through the Print screen and saved for using; 3) To grab some representative pictures in the video by Video Snip and be saved as an image file, and then they are applied to the courseware.

Production of animation material The courseware mainly uses 3Dmax StutioR3 to produce. We make a complete technique demonstration , venues, background about Back Layout from different angles. To make full techniques, the complete technical essentials of Back Layout, action diagrams of elite athletes and teaching illustrations are adopted to abstract an idealized model of three-dimensional animation.

Production of audio material Three kinds of sound are usually used in the courseware: 1) The sound of explanation is recorded based on the text script;2) MIDI music which is as a background;3) The sound is collected from the videotape by acquisition card. The sound of explanation is required to be accurate, clear and reasonable.

Production of video material Sports technology courseware is to help students develop the right, intuitive and clear demonstration actions. In the process of making video material, the major outstanding audio-visual materials should be chose. In the collection, sound, no sound, slow motion and normal speed action are collected according to the different needs of courseware. Meanwhile, a number of important teaching methods and typical errors are recorded with a Panasonic video camera by athletes and student.

Overall production of courseware The overall production of courseware is began after the text, images, video, animation, audio, and other materials are ready. The overall preparation of courseware is mainly based on the script cards and CAI courseware hierarchy diagram. Courseware production is mainly done by Authorware. This part is not just to move the contents of the script card, it also includes modification of forms about information presented, background, re-election of music, text size, color, font changes, etc. The overall production is made through page after page, with hypertext links to achieve its strong interaction, forming a three-dimensional network structure between the various pages.

Courseware Trial

After completion of the overall synthesis and preliminary modifications, courseware should normally be in the teaching of trial by teachers and students for testing the applicability of courseware, and then amendments are proposed to make further modifications.

Sorting and Packing of Software

According to comments on the courseware for further revision, then it is burned to a CD, so you can run directly on other computers.

Application and Evaluation of Courseware

In order to explore the law and teaching mode of using multimedia CAI courseware, a questionnaire for the Multimedia CAI Courseware for Back Layout Teaching is adopted from 35 students of 2010,2011 grade in Sports Institute of Henan University .From the results of the questionnaire, students basically give full recognition evaluation. In addition, eight experts who are long engaged in teaching and training of back layout and six specialists who are engaged in production of CAI courseware are invited to evaluate. Finally, they agree that the courseware has great innovation and reach the advanced level of similar products.

Analysis and discussion

Ideas of Courseware Design

Guiding ideology of courseware system Multimedia CAI proposes a new teaching mode that emphasizes the initiative of students in the process of teaching and creates an environment where students' interest in learning and desire for knowledge is stimulated with providing an electronic teacher that is ready to give guidance and correct errors. Therefore, the thought of combining the teaching design with advantages of computer software is as the guiding ideology of making Multimedia CAI Courseware for Technique Teaching in Physical Education.

Theoretical basis of courseware design Courseware is often developed for certain objects and should be determined first in part of courseware design.

Basic Principles of Courseware Design

General principle; control principle; scientific principle; optimum principle of media selection and combination; friendly interface and simple operation principle.

Superiority of Multimedia CAI Courseware of Physical Lessons Using Technology

1) the difference in favor of teaching, individualized;2) conducive to the excellent teaching experience and promote outcomes;3) There are factors beneficial to students' intellectual and non-intellectual factors;4) will help save teachers' strength and energy to ensure that teachers have a good mental state to creatively preparation, teaching.

Conditions of Track and Field Teaching Multimedia CAI Courseware

Hardware facilities The simplest condition is that track and field surrounded by one or more CAI classrooms, so teachers can meet the multimedia presentation of CAI. The best conditions is that the student dormitory is equipped with a computer or open to students at any time multimedia CAI classrooms, students in school can also use multimedia CAI courseware preview or review and consolidate. With the development of technology standards and the improving of people's living standards, computer prices have also dropped dramatically, which has achieved the CAI teaching sports technology provides a viable condition.

Software environments The software should keep up with the basic hardware facilities. It mainly consists of two meanings: First, the basic requirements for teachers and students, teachers and students should have basic computer knowledge and use of modern media and cameras and other basic skills, the second is to have a good multimedia CAI courseware, this is a "source "problem, if there is no good multimedia courseware, no matter how good the hardware can't also play a role.

The Usage of Sports Technology Teaching Multimedia CAI Courseware

In order to achieve good teaching effect in the teaching process we usually require students to preview before class, conscientiously study in the classroom, consolidate and improve after-school .Using multimedia CAI courseware for teaching, should also teach these three main teaching.

Conclusion and recommendations

Conclusion

1) Based on the optimization of teaching courseware design ideas and teaching objectives and content, design, writing scripts and script courseware to create multimedia CAI courseware card is the key link;2) for text, images, animation, audio, video and other media material collection and skillful editing is a important prerequisite of multimedia CAI courseware ;3) "Physical Technology Course Multimedia CAI Courseware" development and application of teaching provides advanced and visual teaching methods. Make up for the deficiencies of conventional teaching and have improved the students' sense of participation and enthusiasm for learning. It has deepened students' understanding of knowledge, the abstract becomes concrete, revealing the nature of the problem, students can promptly correcting, review, strengthen and consolidate the knowledge, help to optimize the teaching process.

Proposal

1) Updating of education, teaching ideas, attaches great importance to the significance of CAI technology in education and teaching reform.2) The higher education departments should strengthen the teaching of multimedia hardware construction, pay attention to cultivating teachers to use modern media awareness and to provide teachers with good learning opportunities.3) the higher authorities should be system teachers, will be included in a multimedia CAI courseware condition teacher induction, and get its appraising the linked.4) Teachers themselves should be a sense of urgency, and should take the initiative to accept new things, and introduced it into teaching, to improve the teaching effectiveness and the quality of classroom teaching.

Economic Analysis and Governance Countermeasure of Overload and Out-of-Gauge on the Highway

Lijun Zhou

School of Economy and Management, Nanjing Institute of Industry Technology, Nanjing, 210023, China

email: zhoulj@niit.edu.cn

Keywords: Highway transport; overloading; governance countermeasures

Abstract. With the development of highway transport, the social harms caused by overload and out-of-gauge on the highway become prominent. Though it is banned for a long time, it continues to exist. The article conducts the research that the most fundamental reason for the overload and out-of-gauge is that the transport operators pursue to maximize benefits from the perspective of economy. Then such five countermeasures for solving the overload and out-of-gauge transport shall be put forward: changing the punishment mode of overload, reforming multi-sectoral administration pattern, taking the road of intensive development, strengthening transport vehicles market management and making full use of modern science and technology.

Introduction

Highway transportation is one of five modes of transportation. For a long time, highway transportation plays an important role in our national economy and daily life. Especially in this twenty years, with the rapid economic development and under the support through national policies, the road infrastructure improve constantly with the increase of service stations and expansion of the scope, and a wide range of flexibility in space, time, batch, transporting conditions and services. So, highway transportation gives full play to the "door to door" transportation advantage. However, in recent years, the problems relating to overload and out-of-gauge intensify, which has hindered the economic development of transportation. With the widespread of overload and out-of-gauge, the roads are badly damaged because of the long-term overloading rolling, resulting in the great reduction of traffic efficiency and serious impact on the lives and property of the people, which is dubbed highway killer" and "accident culprit". Therefore, study on the overload and out-of-gauge in the highway transportation has a great practical significance.

Definition

The so-called overload transport indicates that transporting vehicles on the highway are loaded with excessive weight (beyond the approved load). Public security traffic management department shall review whether the net weight, total weight and axle load, which are stamped on the vehicles by their manufacturers, conform to the requirement in accordance with national standard. And the vehicles in conformity with the standard shall be registers and granted operation.

The so-called out-of-gauge transport indicates that for the vehicles on the highway, their total weight, axle load or dimension exceeds the specified standard.

Analysis of Overload and Out-of-gauge of Highway Transportation from the Perspective of Economy

As an economic activity, highway transport carriers lay emphasis on the profits in transportation activities process. If R represents transport profits, S represents transport revenue and C represents transport cost, the transport profits may be expressed as follows,

$$R = S-C \quad (1)$$

Transport revenue is mainly defined by freight load, transport price and transport distance so you can use S = f (m, p, l), where:

m represents cargo load with ton as unit

p represents transport price with ton and km as unit

l said transport distance with km as unit.

Then, $R = S-C = f(m, p, l) - C$ (2)

As transport revenue is proportional to the transport price, freight load and transport distance, the f (m, p, l) in (2) can be expressed as:

$f(m, p, l) = p \times m \times l$

According to whether transport costs vary with the transport mileage, transport costs can be classified into fixed costs C_f and variable costs C_v. Fixed costs are composed of the depreciation of the vehicles C_1, the salaries of administrative staff C_2, driver wages C_3, employee benefits C_4, transportation management fee C_5 and insurance C_6 while variable costs include fuel C_7, repairs C_8, tire fees C_9, tolls C_{10}, freight surcharges C_{11} and other penalties C_{12}.

Given that variable costs are proportional to the distance and freight load, they can be expressed as:

$C_v=k\times m\times l$ （3）

Here, k consists of such variable items as fuel C_7, repairs C_8, tire fees C_9, tolls C_{10}, freight surcharges C_{11} and other penalties C_{12}. That is, $k = f(C_7, C_8, C_9, C_{10}, C_{11}, C_{12})$, which means the necessary variable cost per unit of transport mileage. Then formula (2) can be expressed as:

$R=S-C= f(m, p, l) - C=p\times m\times l-k\times m\times l-C_f=(p-k)\times m\times l-C_f$ （4）

As can be seen from the above expression, when p> k, the transport carrier is qualified for transportation. Though the profit is negative, the variable costs and part of fixed costs can be made up. When $(p-k)\times m\times l>C_f$, , the transport carrier obtains profits. When transport distance is specified, in order to maximize profit, one way is to increase freight, which is not feasible under current fierce market competition because the transport carrier tends to gain a competitive advantage through reducing price while the other way is to improve the freight load, which is feasible under the current circumstance. Correspondingly, the carriers may obtain higher profits though tolls increase and possible fines occur for overload and out-of-gauge.

Solutions to Overload and Out-of-gauge of Transportation

1. Learning from foreign experience and changing the mode of penalty for overload

In Germany, more than 700 checkpoints are set along the national highway of a total of 11,000 km to test the overload of the vehicles and the driver timeouts. If the driver is judged for overload for the first time, the case will be registered and the driver will receive a verbal warning. The driver will be imprisoned for three months for the second time. If the driver is judged for overload more than three times, he/she will be deprived of his/her driving license and on the blacklist who may not work at driving all his/her life, thus enabling him/her not to drive overloaded vehicles.

In Japan, if the driver is judged for overload, penalty will be claimed on the driver, owner of the goods and the transport enterprise. According to the regulation of Japanese laws, the driver will be given punishment of stop driving for overload for the first time. If the driver commits it again, the duration of stop driving as punishment shall be lengthened, even the driver may be deprived of his/her driving license. Among them, 1 point shall be deducted from the driver if he/she is given the punishment of stop driving for ten days. If 20 points accumulated in three years are deducted from the transport enterprise, it shall be published in the list of violators; if 50 points accumulated in three years are deducted from the transport enterprise, it shall be ordered to suspend business to bring up to standard; if 80 points accumulated in three years are deducted from the transport enterprise, its business license shall be withdrawn. If the owner of the goods knows its overload, he/she shall be fined not to sell the goods or distribute them to the vending companies otherwise the owner shall be sentenced to less than six months in prison or a fine of 100,000 yen.

To learn from the operation in Germany and Japan, our traffic management departments shall establish the credit files of the transport enterprises and business vehicle driver and network with the highway information systems in different provinces. Once the vehicle is specified for overload, the related information about the transport enterprise and ownership shall be defined so the corresponding penalty shall be claimed on driver, transport enterprise and owner. For driver, the violating behavior shall be registered and published. And for a vehicle, if the notice is published less than 2 times, the driver shall be fined; if the notice is published more than 3 times, his/her driver qualification shall be withdrawn. For transport enterprise, if the vehicles with the notices published for overload exceed a certain proportion, its qualification shall be reduced.

2. Reforming multi-sectoral co-administration pattern and forming specific law enforcement agency

At present, there are many units who are involved in administering overload and out-of-gauge, such as Ministry of Communications, Ministry of Public Security, the National Development and Reform Commission, the State Administration of Quality Supervision, State Administration for Industry and Commerce, the State Administration of Work Safety. However, it is difficult to define their responsibilities respectively resulting in duplicate law enforcement: if they can benefit from the enforcement, they will struggle to handle it while if they have to burden the responsibility, they will put it aside. On the other hand, Enforcement standards in the enforcement process are not unified so the duplicate penalties may occur for the same overload and out-of-gauge. For the improvement, centralized management is a general way, which lack long-term, unified and coordinated supervision. Once the centralized management period is over, the overload and out-of-gauge will re-occur. Indeed it is hard to achieve the purpose to eradicate the overload and out-of-gauge in highway transport. Therefore, the current governance mechanism should be changed to form a specialized law enforcement agency so as to clarify their responsibilities, ensure the fairness and avoid duplicate law enforcement.

3. Changing the traditional management model and keeping to networking, intensive and large-scale development path

At present, the number of enterprises in the highway transport market is large, scale small and competition intensive. The main reason is that the barriers for entry to freight transport market are set very lowly, which is affected by economic theory of traditional transport. Before the reform and opening up, highway transport had been considered as an industry short of the benefits of economies of scale and its scale is confined to a smaller scope. After the reform and opening up, state-owned transport enterprises generally carry out vehicle-contracted policy so self-empolyed transport increases with an annual rate of 20%, further exacerbating the decentralized management.

To change this situation, the relevant administrative departments, industry associations, transportation companies can take the following measures:

1) They should adjust the existing vehicle tax policy, set the high-standard entry to the freight market, encourage the transport enterprises to make mutual acquisition and merger so as to establish a number of large transport conglomerate according to modern enterprise system, encourage self-employed persons to affiliate to large-scale transport enterprises and limit new micro transport enterprises to gradually die a natural death.

2) They should develop society-oriented transportation system, encourage the existing enterprises to outsource self transport so as to form specialized transport market with the result that highway freight industry develops towards the healthy and orderly direction and promote its comprehensive, coordinated, sequent and sustainable development.

4. Strengthening transport vehicles market management and eliminating violating and illegal action in the vehicle production

Transport vehicle production chain management should be strengthened so as to prohibit illegal modification of vehicles and the production of illegal overloaded vehicles. Freight vehicle production management directory should be put in order and straightened and relevant accountability system should be set so as to eliminate "big tons marked with small tons" on the vehicle and resell product certification. Efforts should be made to investigate illegal enterprises. For

the vehicle with "big tons marked with small tons", public security vehicles management department should order them to correct its permitted weight or renew its driving license. Transport departments should press the owner for the payment of its extra load in the stipulation.

Traffic police should also strengthen the source management of vehicle registration so as to check its registration. Once the technical data on driving license are inconsistent with actual technical ones, its registration is not approved. Related departments shall ban vehicles of unauthorized modification and self-employed persons from driving according to law so as to prohibit vehicles of illegal modification from running on the road.

5. Making full use of modern technology to increase the tracking and monitoring of transport vehicles

At present, in China, related departments of traffic management and road administration enforce the law to check on the highway. Because of manual check, there are some disadvantages of high cost, inefficiency, unable to conduct long-term continuous supervision for a whole day and all the time, and it is possible for law enforcement officers to make arbitrary decisions. The supervisory practice for ten years shows that the supervisors can't effectively administer overload and out-of-gauge but cause a variety of arbitrary fines with the result that the phenomena of the overload and out-of-gauge on the highway intensify.

To effectively solve this problem, it is necessary to make use of modern technology to build a modern, all-the-time highway monitoring system. The system includes the following features: Firstly, vehicle identification system shall be established. The information interaction through the system can be achieved. If necessary, vehicle information, goods information and owner information will be automatically transmitted to the monitoring station of transportation management department.

Secondly, the supervision system of road transport management departments shall be established including automatic weighing system in the charge station and all-levels controlling centers connected through network. Through such modern technology as the Internet, Internet of Things and GPS systems, transport vehicle can be connected with the supervisory system of transport management departments so as to form the highway supervision system automatically through computers to handle the vehicle information. Through the system, the related departments can conduct all-sections, all-weather and all-time real-time supervision for transport vehicles.

In short, the governance of overload and out-of-gauge transport is a long and arduous task. In the process of governance, if we can introduce the practice from mature markets, use new science and technology and innovate management patterns with the collaboration and perseverance of different departments, we can guarantee the smooth flow of the vehicles on the highway in good condition so as to promote the healthy and rapid development of the economy.

Keywords: balancing urban and rural development; rural population hollowing; governance mechanism; development anthropology

Abstract: Under the process of balancing urban and rural development, many villages appeared the phenomenon of rural population hollowing. The number of rural population reduction and demographic imbalance greatly influenced the process of building new socialist village. From the perspective of development anthropology, to solve the problem of rural population hollowing fundamentally, we must reflect the existing ways to governance rural population hollowing and propose the political, economic, social and cultural governance mechanism to governance rural population hollowing under the process of balancing urban and rural development from the perspective of system correction mechanisms and multi-center levels of governance according to the paradigm of urban-rural dual system analysis.

1. Introduction

Under the background of the central attaching importance to three agriculture-based issues, the phenomenon of rural population hollowing is the important difficulty of balancing urban and rural development. About agriculture-based issues, the eighteen reports of the Party point out “the problem of farmers is the priority to other problems, the integration of urban and rural development is the fundamental way to solve three agriculture-based issues" [1]. Balancing urban and rural development and adhering to the new urbanization road of Chinese feature is the inevitable choice and effective way to solve the three agriculture-based issues. Since twenty-first Century, China has entered the stage of rapid urbanization. With the rural population of non-agricultural employment and income increasing, many villages appeared the population hollowing phenomenon, which greatly affects the process of building new socialist countryside. In fact, the problem accumulation and of contradictions intensification under the background the long two structures of urban and rural areas, especially the current rural hollowing problems in China because of some deviation of urban and rural system are far more complicated and more serious than other countries. The sixth national census data show that the Chinese population geographical distribution is undergoing profound changes; the central province of hollowing trend is higher than the eastern and western provinces. Therefore, to solve the three agriculture-based issues fundamentally, we must realize the coordinated development of urban and rural, and reflect on the rural hollowing governance ways and put forwards the following suggestions to realize the rural population hollowing governance.

2. Local Cultural Demand Realization Mechanism

The development of anthropology emphasizes respect for diversity of local culture, respect for history that only a specific area formed the social and cultural knowledge, sustainable development can be achieved in rural areas. Just as Agrawal said: "the local knowledge is independent, has obvious geographical characteristics, in its holder, life, so try to summarize the essence, isolation, archiving, conversion will be a very difficult thing" [2]. In the process of governance in rural population of hollow, we must improve the local cultural appeal mechanism, because it reflects the local requirements, and exists in the local people's life. One is to establish respect for local culture consciousness. In the face of rural urbanization in the process of local culture edge trend, we must reassess the role and status of local culture in the maintenance of natural ecological balance and sustainable development. The second is a flexible mechanism to realize the growth of rural population. For example, in the course of urbanization, poverty area in remote mountainous areas, ethnic minority areas, a large number of rural labor transfer makes the lack of care for elderly population, at the same time, implementation of the family planning policy of rural population, the child will be unable to take good care of the elderly left behind. Therefore, respect for these regions fertility culture growth, fertility policy of rural population local adjusted to "promote a tire, allowing a second child, put an end to the three fetal", so as to solve the rural population and reduce the left behind elderly care problem. The third is to perfect the mechanism of migrant workers returning home for business. In order to realize the migrant workers pining for home feelings, we can encourage migrant workers to return home business, improve migrant workers' entrepreneurship ability of returning home, from the aspects of policy support mechanism, the human capital investment mechanism, three-dimensional training mechanism, resources integration mechanism. Which not only can solve the rural surplus labor employment problem, solve the left behind elderly, rural left-behind children and other issues, to provide the necessary talent support for new rural construction, but also promote the coordinated development of urban and rural areas to the adjustment of rural industrial structure?

3. The Bottom-up Participatory Social Development Mechanism

In the view of developing anthropology, the development of urbanization of rural land resources is not intended to plunder or occupation of the market the vast rural areas, but in order to help people in rural areas get rid of poverty, improving the living standards of rural residents. It therefore, in the course of urbanization, especially in the urban and rural power resources, land resources, human resources and the process of rural urbanization mode, local employment transfer mode and rural community model, must fully consider their own resources of local and traditional culture, advocate the bottom-up participatory social development mechanism.

3.1 The empowerment and participation mechanism

Empowerment is an important theory and anthropological research methods development, rural population hollow governance is to achieve the rural transfer of rights and the transfer through the design of the system and, at the same time by rural residents to participate in power and supervision power, eventually return to and in the service of the rights of rural residents. Empowerment is connected with the concept of community participation in, the real community participation in practice to have at least the following characteristics: with transparent decision-making process; a high proportion of community residents participation rate; high degree of meaningful local participation; fair and effective procedures; high levels of local ownership and management of [3]. Practice has proved that the development of urban and rural development, rural itself must be fully carried out the social mobilization through a bottom-up approach to rural residents to actively participate in. For example, the planning of small towns, the village center planning and community planning, should be vigorously publicity, respect the people's right to know and the right to participate in the mobilization of the rural residents, local participation in regional transportation,

housing, tourism, education, medical and other planning and decision making process, on the basis of fair and reasonable process, widely listen to their ideas and for planning and construction of the attitude, do demonstration and feedback, good constructive ideas reflected in the plan. At the same time in the planning and decision-making and implementation process, to fully absorb the rural residents to participate in, so they have real decision-making power and supervision power, thereby reducing them to the planning of the resentment, correcting and smoothing implementation of the plan.

3.2 Rural hollowing mechanism of multi center governance

Hollowing out of rural population is a complex issue, involving government, enterprise, community residents, multi stakeholder relations, the government cannot do without the various stakeholders in the overall participation. The rural population hollow governance mechanism of multi center has the following four characteristics: management is not a set of rules, is not an event, but a process; the basis of governance process is not controlled, but coordination; governance not only relates to the public sector, or including private sector; governance is not a formal system, but continues interactive [4]. In combination with the specific practice in the process of urbanization of the rural population, hollow governance should start from the relationship between government, enterprises, residents, community organizations and other social organizations, to explore the rural population hollow governance mechanism of multi center, thus the effectiveness of rural population hollow governance to ensure, to improve the overall level of urban and rural economic and social development.

4. Balancing urban and rural political and economic system error correction mechanism

Anthropology of development history so far, has been stressed that human is in the center position in the development, including the development goal is to realize the all-around development of human development, the way to pay more attention to people to participate fully in. Cultural diversity and development practice and advocated to respect area, the opposition in the development of practice and the common people and their cultural marginalization of local. In the course of urbanization, the household registration system reform is an important breakthrough dualistic structure change of urban and rural areas, it is not only a relates to land adjustment, allocation of resources economic problem, but also a political issue involving the identity transformation and social stability. But in the urban and rural practice, we have had the force transfer, jump on the bandwagon, a turn of, copy and many other deviations in the process of the reform of household registration system, the rural population is becoming more and more serious problem of hollow. So learn from the development of theories and methods of anthropology, must carry out rectification to the reform of the household registration system.

4.1 Promote the reform of household registration system

The general office of the State Council in 2012 issued the "Office of the State Council on actively and steadily push forward the reform of household registration system notice" clearly pointed out that some local household registration reform chaos, "in some places, regardless of local economic and social development of the actual situation, the one-sided pursuit of rapid urbanization; in some places is not divided city category regardless of the city's comprehensive carrying capacity, a located in the city of taste to relax the conditions; in some places to break through the national policy, the damage to the vital interests of" [5]. Therefore, the reform of the household registration system must be based on the actual situation around, fully consider the city scale and structure of local public resources, the reasonable measure of the city's comprehensive carrying capacity; fully respect the farmer himself, not a mandatory or compulsory reclaim land and contracted arable land, woodland, grassland; gradual reform of the household registration system, and gradually open the

residence permit system and the relaxation of the settled standard in towns, farmers clear after achieving the right content and sequence.

4.2 Overall the household registration system matching reform measures

Fundamental reform of the household registration system is the need to register on stripping the interests of attachment, the household registration system to return to its social function, so it should be the reform of household registration system orientation transformation of household register management to identity management. At the same time, the household registration system reform measures in the national legislation should be introduced to the household registration law and related legislation as soon as possible, to guarantee citizens' freedom of movement and clear registration transformation procedure, rights, obligations and specific content. The second is to improve the government performance evaluation mechanism to reduce green, the proportion of economic construction in achievement assessment, strengthening social justice, environmental protection, people's livelihood security index. Second is to improve the social security system in urban and rural areas. Increasing the intensity of the central financial transfer payment, the farmers, migrant workers, urban workers and city resident’s social security policy objects into the construction of unified financial payment system, to promote the social security system effective cohesion among regions.

5. Inclusion

According to the core thought and main views of the development of anthropology, the innovation of the rural population hollow governance model can indeed provide feasible path selection to solve the "three rural problems". But to truly realize the coordinated development of urban and rural must be in the perspective of developing anthropology to urban and rural two element analysis paradigm to investigate the rural population hollow governance in the process of urbanization in the political, economic, social and cultural system realization mechanism from system error correction mechanism and multi center governance.

The Application of Factor Analysis in the Study on Cultural Industry Competitiveness Evaluation Index System

Sun Ping

Department of Management Tianjin University of Technology, Tianjin, China

wy_sp@126.com

Keywords: competitiveness of cultural industries; ANP; factor analysis; SPSS

Abstract. Based on the premise of an existing condition data, using factor analysis methods to build a cultural industry competitiveness evaluation index system and evaluation model, the corresponding indicators in the model will be evaluated at the final evaluation results. Statistical analysis using SPSS software, score differences in various parts of, analyses the major gaps.

1. Introduction

Cultural industries are accompanied by cultural restructuring and emerging new industries, reform of cultural system began in 2003; The Sate Council has released "Cultural industry revitalization plan" in 2009, rising to promote the development of cultural industry of national strategic level. In recent ten years, Development of China's cultural industries have made great strides, rendering out of healthy, good momentum of vigorous development. Value added of national cultural industries annual average prices rising faster than23% in 2004-2010. Chinese culture and value added of industry corporate units achieve 11052 hundred millions in 2010, GDP share of 2.75%. In 2010 the emerging cultural industry has rapidly development. Strategic emerging cultural industries are growing faster than 50%. Cultural industry has become a pillar industry of local economic development. But at the same time China's cultural industry development level is not high, dynamic strong enough. With increasing spiritual and cultural needs of the people are not fit. And even better adapted to the Socialist market economic system is not.

Competitiveness of cultural industries is a barometer of the development of cultural industries. Cultural industries ' competitiveness has a variety of forms. From the point of view of input-output, its largest gains with minimal investment; from the internal structure of the cultural industries, it expresses for the cultural industries of various rational and effective combination of factors of production. From the spirit of the cultural industry, it provides the public with a growing wealth of cultural products to meet the spiritual needs of the public. In the regional context of increasingly fierce competition, the importance of enhancing the competitiveness has particularly cultural industries. It is crucial that a province has a complete and accurate evaluation of cultural industry competitiveness.

A provincial cultural industry competitiveness situation, depending on the overall environment in the province, is that provincial and municipal productivity development level, various production factors, cultural needs and cultural market development, corporate governance, government policies and the legal situation, cultural traditions of a variety of factors, such as a combination of results. The intention of this article is trying to create a culture of covered carrier, cultural content, cultural, spiritual and cultural value of the comprehensive evaluation index system and the system on the basis of comprehensive analysis of the competitiveness of cultural industries in other provinces, thus contributing to the competitiveness of cultural industries in different provinces can be integrated sorting and evaluation.

2. Construction of index system

2.1 Principles of construction of index system

Establishment of the index system has the following basic principles: focused representation, the system of comprehensive principles, stable principles of comparability, concise scientific principles,

principles of combining quantitative and qualitative indicators, indicators of accessibility principles. In addition, the indicators system should not only describe the combined static and dynamic characterization. Not only has the evaluation function, but should also develop early warning of potential, future role.

2.2 Choose of index system

Based on the above setting principles, we will be integrated system analysis and reasonable factors, presents a comprehensive evaluation index system of three levels (see table 1):

(1) Cultural industry strength, which includes: talent of cultural industry; financial inputs to the culture industry; the attraction of foreign capital.

(2) Cultural values, which includes: per capita GDP; GDP proportion of the tertiary industry; proportion of residents ' cultural consumption.

(3) Carriers of culture, which includes: engine of the tourist industry to the cultural industries; education industry to the cultural industries of engine; engine for cultural industries of the information industry.

(4) Cultural resources and infrastructure, which includes: resource abundance; cultural quality of creative and business talent; corporate management standards in culture; the creative industries.

Table 1. Cultural industry competitiveness evaluation system

objective	standard	target
Cultural industry competitiveness evaluation	Cultural industry strength	talent of cultural industry
		financial inputs to the culture industry
		The attraction of foreign capital.
	Cultural values	per capita GDP
		GDP proportion of the tertiary industry
		proportion of residents ' cultural consumption
	Carriers of culture	engine of the tourist industry to the cultural industries
		education industry to the cultural industries of engine
		engine for cultural industries of the information industry
	Cultural resources and infrastructure	resource abundance
		cultural quality of creative and business talent
		corporate management standards in culture
		the creative industries

This indicator system, industrial-strength, cultural values and cultural carrier of culture, cultural resources and infrastructure and so on, basically includes the impact on the competitiveness of China's cultural industry has a relatively important factor. From a horizontal view, these factors and its indicators covers the main developments in the industrial sector of the cultural industries and production capacity and production of cultural products and services, cultural consumers ' spending power and intentions, cultural level of market development, human resources and research capacities in the industry, industrial raw material for the development of resources and facilities. From the vertical view, these factors also constitute a "manufacturer + carrier + → → cultural products and cultural resources and facilities services culture consumption markets", the complete production and consumption of products and services in the industry.

3.Factor analysis model[1]

Basic idea of the factor analysis is based on the correlation between variables grouped the original size, with dependencies between variables in a group higher, but lower variable correlation between the different groups. Factor analysis model as follows:

(1) $X=(X_1,X_2,....,X_p)$ is the observed random vector, and its expect vector is 0, covariance and correlation matrices are equal.

(2) $F=(F_1,F_2,....,F_m)$ (m< p) is an observation vector, and its expect vector is 0, covariance Cov (f) =I, that is, the components of a vector are independent of each other.

(3) $\varepsilon=(\varepsilon_1,\varepsilon_2,....,\varepsilon_p)$ and F are independent of each other; and its expect vector is 0. Covariance matrix is a diagonal matrix, that is, between the components are independent of each other, so model:

$$\begin{cases} x_1=a_{11}f_1+a_{12}f_2+a_{13}f_3+...+a_{1k}f_k+\varepsilon_1 \\ x_2=a_{21}f_1+a_{22}f_2+a_{23}f_3+...+a_{2k}f_k+\varepsilon_2 \\ x_3=a_{31}f_1+a_{32}f_2+a_{33}f_3+...+a_{3k}f_k+\varepsilon_3 \\ ..... \\ x_p=a_{p1}f_1+a_{p2}f_2+a_{p3}f_3+...+a_{pk}f_k+\varepsilon_p \end{cases} \quad (1)$$

Because the models are for the variables, various factors are orthogonal, therefore, also known as r-type orthogonal factor model, Its matrix form as: X = AF+ε。 F is called the public factor of X, the matrix A is called the factor load matrix, the factor load a_{ij} is the correlation coefficient of the i variable and j factor, it is reflected the importance of the I variable on the J factor. There are two statistics is very important in the factor load matrix A, is Variable common variance and common factors contribution; ε is called the special factor of X. The larger of the element absolute of a_{ij} in matrix A, the more of X_i and F_j dependent. it is one of the purposes of the factor analysis that to find the value of each factor loading. If the all a_{ij} (j = 1, 2,…., m)of factor loading matrix A is calculated , sorting according to size, it can be extracted from the most influential public factor。When the factor analysis model is established, an important role is the application of factors analysis model to evaluate each sample position in the model as a whole, that a comprehensive evaluation.

4.Evaluate consequence analysis

This paper empirical analysis of Beijing, Shanghai, Tianjin, Nanjing, Dalian and other, all quantitative indicators from the 2011 Statistical Yearbook and the Government Statistical Web site exposed data, qualitative indicators for listening to the views of relevant experts, in accordance with the Delphi technique eventually formed. The analysis results on factor analysis model.

(1) In the SPSS software runs on data, came to the correlation matrix. Select using principal component analysis and extraction of common factors. The first three factors explained variance total variances of more than 93%, while the former two factors would explain the two, essentially full response of many indicators information.

(2)Maximum orthogonal rotation method has been used variance factor rotation, after orthogonal rotation, the Comparability of indicators variables (common) did not change, but the common variance contribution factor is no longer the same as original, marked reduction in contribution of factor 1 and factor 2 contributions increased significantly. Bartlett estimates worked out a sample of the comprehensive index score, factor scores and ranking of cities as shown in table 2.

Table 2 The factor scores and rankings of Bartlett Estimation

City	F_1	ranking	F_2	ranking	scores	ranking
Tianjin	- 0.223	3	-0.48	4	- 0.0491	4
Beijing	0.853	2	1.22	1	0.928	2
Shanghai	0.977	1	1.15	2	0.931	1
Nanjing	- 0.479	4	0.101	3	0.067	3
Dalian	- 0.827	5	- 0.742	5	- 0.786	5

The analysis conclusion Comparative of Factor Analysis is almost identical. The competitiveness of urban cultural industry development level of overall branch 3 tier: first echelon represented by Shanghai, Beijing, Tianjin, Nanjing, as the representative of the second Echelon, to Dalian as the representative of the third Echelon. Due to the strength in the index system and indicators per capita, thus the comparability between provinces and cities. Judging from the results, in Shanghai to a higher value in the first place, visible in recent years in Shanghai, along with the economic development of the cultural industry is continuing to grow. Economically more developed and people's living standards higher areas on the development of cultural industries, also have some advantages. Dalian with strength and per capita indicators of good performance overcomes the lack of total followed suit.

5. Conclusion

Studies on the basis of this article at home and abroad, scientifically selected representative cross section of 5 targets, the establishment of a comprehensive evaluation index system for regional competitiveness of cultural industries, innovation is the establishment of an independent evaluation system, analysis of the model of factor analysis method.

Due to limitations in time and article space, only 5 cities were selected based on this article, selection of indicator system should be further improved. Further, we can also through the analysis of time series data to study areas where credit conditions change over time. In addition, during factor analysis, orthogonal rotation method for maximum variance (Varimax), the factor score regression estimation method using “Bartlett” estimate of the consequences of this law and “Thomson” estimate method is slightly different, could have some impact on results. Causes also need further analysis.

Keywords: forging enterprise, rapid bidding, Activity-Based Costing (ABC), cost composition, enterprise business process

Abstract. Forging, as a traditional machining, plays an important role in Chinese economics construction and equipment production. It is essential to enhance the level of management for forging enterprises. This study aims to reveal the cost composition of forgings and the law of bidding, and thereby make an integrated and intelligent bidding for forgings with reduction of bidding the difficulty and improvements of accuracy. Activity-based costing bidding for forging is studied in depth after analysis of forgings cost composition and enterprise business process. The research promotes the integration and intelligence of forging bidding as well as the accuracy and reasonableness.

Introduction

Forging, as a traditional machining, plays an important role in Chinese economics construction and equipment production. Forging production provides the necessary parts for industries of automotive, agricultural machinery, iron and steel smelting and so on [1]. The importance of forging industry to national equipment manufacturing industry is self-evident. Thus, it is essential to enhance the level of management for forging enterprises [2]. However, with the development and expansion of the forging industry, some problems forging enterprises facing also slowly emerged: increased competition and diversities of customer requirements for forging quality as well as delivery and after-sales service [3].

Bidding is an important link between forging enterprise and customers. Also, it is critical for customers to make supplier selection decision and for forging enterprise to make order acceptance decision. The price of forgings is essential for the survival of forging enterprises. With the increased competition due to the open market, customers are increasingly sensitive to the price of forgings. Empirical bidding by sales staff and managers in the past cannot satisfy market competition and customer needs because of slow response, imprecise bidding and other factors in actual business [4].

This study aims to reveal the cost composition of forgings and the law of bidding, and thereby make an integrated and intelligent bidding for forgings with reduction of bidding the difficulty and improvements of accuracy.

Principle of cost accounting based on ABC

Activity costs are generally composed of direct material cost, direct labor cost and manufacturing cost. The first two can be directly obtained by statistics of finance department, and manufacturing cost is required for detailed decomposition and calculated by multiplying each activity cost ratio and the number of activity costs. As for forging enterprise, direct material costs include forging materials and packaging materials, and direct labor costs are denoted by employee benefits. Manufacturing costs need to conduct a detailed investigation of each project to analyze each activity as well as corresponding cost ratio. The price based on ABC can be calculated as [5]:

$$P = \sum_{i=1}^{19} (\alpha i \times \beta i) + \lambda + \gamma \tag{1}$$

P : Bidding price; αi : The number of activity drivers; βi : Activity cost ratio;

λ : Direct material costs; γ : Direct labor costs.

Production cost accounting based on ABC

(1) Manufacturing costs calculation

Items of manufacturing cost and cost drivers are listed in the first two rows of Table 1. After investigations and analysis of forging enterprise, it can be concluded:

1) Products are generally produced and delivered in batches according to customer requirements, so the number of production planning times is the same as of delivery.

2) The number of process analysis times is the same as the number of product types.

3) When process planning, work hour is given directly by the craft.

4) Heat treatment times are determined directly by production department.

5) Free forging products are inspected one by one, so inspection times equal to the number of production as well as cutting and packaging.

6) Equivalent procurement weight is calculated as weight of the blank sourcing.

7) Storage amounts are considered as 10% of WIP (work in product).

8) Since forgings are distributed by forklifts with usually one forging once, so delivery times consistent with the number of productions.

9) Times of after-sales service are considered as 2% of monthly production capacity.

After statistics, the details of activity drivers within a month for A and B, two types of forgings, are as shown in the 3rd and 4th row of Table 1.

Table 1 Items of manufacturing cost and cost drivers

Activity	Cost driver	A	B
Inquiry activity	Number of product types	1	1
Process analysis	Times of analysis	1	1
Delivery assessment	Number of product types	1	1
Production planning	Times of production planning	2	4
Purchasing	Weights of procurement	2820	20000
Cutting	Times of production planning	15	250
Stacking	Numbers of products	15	250
Forging and machining	Work hour	40	120
Heat treatment	Times of heat treatment	3	10
Quality control	Times of quality inspection	15	250
Package	Numberso f packaged products	15	250
Delivery	Times of delivery	2	4
Storge	Storage amounts	1.5	25
Distribution	Times of distribution	15	250
Order	Order times	1	1
After-sales service	Times of after-sales service	0.3	5
Equipment depreciation management	Work hour	76	156
Plants depreciation management	Numbers of products	15	250
Fuel and water consumption	Numbers of products	15	250

According to ABC approach and production costs statistics over a period of time, actual activity costs ratio of each cost drivers can be obtained as shown in the first three rows of Table 2. Furthermore, according to the above analysis, details of activity cost of A&B are listed in row 4th and 5th of Table 2.

(2) Direct material cost calculation

Direct material cost is the amount spent on purchases of rough forging. According to the product of each blank price (RMB / kg), weight (kg) and the yield of production, it can be obtained:

Direct material costs of A = 8.5 × 190 × 15 = 24225 RMB.

Direct material costs of B = 8.5 × 80 × 250 = 170000 RMB.

(3) Direct labor costs calculation

Total labor costs of A and B can be obtained by monthly statistics from financial department, which will be shared by A and B respectively according to the ratio of processing time they occupied. For certain month, total labor cost 12480 RMB. Then,

direct labor costs of A are: 12480 × [76 ÷ (76 +156)] = 4088 RMB
and direct labor costs of B are: 12480 × [156 ÷ (76 +156)] = 8392 RMB
After the above calculations, the details of costs for A and B are obtained as listed in Table 3.

Table 2 Activity cost of A & B

Activity	Cost driver	Cost ratio /RMB	Number of driver	
Inquiry activity	Number of product types	100	A	B
Process analysis	Times of analysis	300	1	1
Delivery assessment	Number of product types	100	1	1
Production planning	Times of production planning	200	1	1
Purchasing	Weights of procurement	0.1	2	4
Cutting	Times of production planning	3	2820	20000
Stacking	Numbers of products	1	15	250
Forging and machining	Work hour	32	15	250
Heat treatment	Times of heat treatment	330	40	120
Quality control	Times of quality inspection	20	3	10
Package	Numberso f packaged products	3	15	250
Delivery	Times of delivery	200	15	250
Storge	Storage amounts	200	2	4
Distribution	Times of distribution	20	1.5	25
Order	Order times	200	15	250
After-sales service	Times of after-sales service	500	1	1
Equipment depreciation management	Work hour	8	0.3	5
Plants depreciation management	Numbers of products	10	76	156
Fuel and water consumption	Numbers of products	20	15	250

Table 3 Cost details of A & B

Plants depreciation management		150	2500
Fuel and water consumption		300	5000
Total		34653	218580

Determination of margin

Under ever-changing market, customer needs tend to be dynamically diverse. Therefore, pricing decisions need to consider a variety of factors. In addition to production costs discussed in the

previous section, delivery capability, ease of forgings, game between business and markets as well as business and customers, etc. are also included.

(1) Delivery

In such a high degree of information technology today, rapid response is an important indicator to evaluate enterprise capabilities. Faster response of business to market and to customers, can account for the initiative in the competition. So delivery has become a major factor affecting bidding. Customer's demand for shorter delivery time will result in more profits of enterprises.

(2) Difficulty machining facing for forgings

For forging enterprises, machining difficulty often depends on the geometrical characteristics of the product as well as internal quality characteristics needs. Facing complex shape (which means higher forging process capability) and higher heat treatment technology demand from customers, highly profitable pricing strategy can be developed.

(3) Market competition

Market competition is also an important factor to consider for product pricing. Whether competitions are intense or not, depends on the threshold of the industry, the number of enterprises in the industry as well as the balance degree of enterprises' capacity in the industry [6]. Overall, more competitive, smaller profits. Conversely, enterprises receive more profits.

Combined with the calculated production cost previously, the final bidding price based on cost-plus pricing method can be obtained. Cost-plus is by far one of the most widely bidding method. According to the above study, final pricing can be decided as follows:

$$P = p_1 \bullet (1+\delta) \tag{2}$$

P - Final bidding price; p_1 - Production costs; δ - Margin

Conclusions

According to the current enterprise's production capacity and market share, expected profit is decided between 5-18%. Those orders from non-VIP cooperative enterprises or profit less than 5% will not be accepted by forging enterprise. Thus, according to experiences from experts and marketing managers, profit margin is set as8%.

Bidding price of A = 34653 × (1 +8%) = 37425.24 RMB.

Bidding price of B = 218580 × (1 +8%) = 236066.4 RMB.

This study focuses on the quick bidding for a forging enterprise combined with ABC and cost-plus method. The presented research can help to reduce the forging cost of forgings, to improve the competitiveness of forging enterprise, and to enhance the management of forging enterprise.

Keywords: Vendor selection; Evaluation index system; Supply chain management; multi-objective decision

Abstract. The quality of the vendor effects on the market competitiveness of enterprises and the whole supply chain, and the vendor selection decision is the key to supply chain management. Focusing on the problem of selecting vendors, this paper introduces the research history and the newest research trends of the design of index system of vendor evaluation and the methods of vendor selection, and presents many widespread theoretical and applications problems. Moreover, assumptions, main ideas, and conclusions of literature related to vendor selection are reviewed and commented.

Introduction

In supply chain management, vendors are the manufacturing center, service quality assurance center and cost control center of the supply chain. Vendor selection has always been considered a key one within purchasing and supply management [1]. Indeed, some considerit to be the most important of all the responsibilities of thefunction, as the choice of vendor has a significant impact on the optimisation of the quality, quantity, timeliness and price of purchased goods and services [2]. Furthermore, vendors have a direct and significant impact on the quality, cost and lead time of new products and technologies needed to meet new market demands. In short, the vendor is the foundation of supply chain operation, and is the key to gain the core competitiveness of the supply chain for the enterprises [3].

With the growing scale of the supply chain, the structure of supply chain is becoming more complicated, which brings more and more supply chain risks [3-4]. Therefore, in the risk management of supply chain, in order to share the supply chain information for all members, improve the response rate and overall flexibility of the supply chain, and enhance the competitiveness of supply chain, we must make prediction, evaluation, control and decision-making for various possible potential risks in internal and external supply chain. In particular, the evaluation and selection of vendors is the foundation and the key in supply chain management, and is the emphasis in risk control of supply chain. Through scientific vendor evaluation and selection, we can effectively reduce supply chain operational risks and improve continued appreciation ability, and provide strong support to establish a strategic partnership among enterprises. However, selection is complicated by the fact that different potential vendors may have different performance characteristics for different attributes. Therefore, vendor selection is an inherently multi-objective decision, which seeks to minimise some evaluation criteria whilst and, at the same time, maximising others. It might be expected that purchasing and supply managers would look to use quantitative methods to help inform their decision-making. However, until recently quantita-tive methods have typically been found to be inadequate and limited [1].

Scholars have focused on two hot issues about the vendor evaluation and selection, i.e., the design of index system of vendor evaluation, and study on methods and models of vendor selection. In the following sections, we present the widespread theoretical and applications problems for the study on the design of index system of vendor evaluation and the methods of vendor selection, in order to

introduce the research history and the newest research trends of vendor selection in the supply chain management.

The Design of Index System of Vendor Evaluation

For the study of vendor evaluation index system, Dickson is one pioneer research scholar. His study was based on a questioneer sent to 273 purchasing agents and managers selected from the membership list of the National Association of Purchasing Managers, and then he proposed 23 criteria as the evaluation indexes for vendor selection[5]. In 1990, another pioneer research scholar Weber reviewed 74 related articles published since Dickson (1966) in order to provide a comprehensive view of the criteria that academicians and practitioners have found to be important in vendor selection. Specific attention is given to the criteria and analytical methods used in vendor selection process [6].

Following these two pioneer research scholars, Dickson and Weber, many scholars have joined the ranks of research on index system of vendor evaluation. The representative outcomes are as follows. Wilson [7] examined the relative importance of supplier selection criteria longitudinally by reviewing the findings of studies published during the past two decades. Those results are then compared with the findings of this study to gain insight about the relative importances of decision criteria used by purchasing professionals in selecting suppliers. Choy and Lee [8] presented an intelligent generic supplier management tool (GSMT) using the case-based reasoning (CBR) technique for outsourcing to suppliers and automating the decision making process when selecting them. The development of GSMT and how the CBR technique is applied is then given, followed by an application of GSMT in Honeywell Consumer Products (Hong Kong) Limited, and 13 evaluation attributes are given to select manufacturing outsourcing vendors. Willis and Huston et al [9] was to aid just-in-time (JIT) manufacturers in selecting the most appropriate suppliers and in evaluating supplier performance, and presented neural network based supplier selection and supplier performance evaluation systems.The proposed neural network based systems are tested with data taken from an automotive factory, and the results show that the proposed systems can be used effectively.

Later, Patton [10] proposed a similar index system of vendor evaluation with Willis. And then Yahya and Kingsman [11] and proposed a similar evaluation system with the literature Patton and Willis by investigating many experienced business managers and executives. But the difference with Patton and Willis is that they further gave the weights of all attributes by using the method of AHP. Petroni and Bragha [12] used the method of Principal Component Analysis to construct a index system of vendor evaluation from the point of supply chain. The composition of his index system is similar to the index system in [10], but they deleted the attributes of the sales support and financial condition, and added the attribute of management capacity. Menon and MoGini [13] studied the vendor selection of the third-party logistics services, and used empirical research methods to prove the effectiveness of the index system for the vendor selection and evaluation of the third-party logistics service.

Recently, Shemshadi et al. [14] treated supplier selection as a group multiple criteria decision making (GMCDM) problem by considering the evaluation index system including the products quality, effort to establish cooperation, vendor's technical level, vendor's delay on delivery and price/cost, and obtained decision makers' opinions in the form of linguistic terms. Then, these linguistic terms are converted to trapezoidal fuzzy numbers. Similarly, Chen and Wu [15] proposed a modified failure mode and effects analysis (MFMEA) method to select new suppliers from the supply chain risk's perspective and applies the analytic hierarchy process (AHP) method to determine the weight of each criterion and sub-criterion for supplier selection such as cost, quality, deliverability, technology, productivity, service, and so on. Especially, they showed that in the emerging supply chain environment, supply chain risk management plays a more important role than ever, so the companies must focus not only on the efficiency of supply chain, but also on its risks. That is to say,

when design the vendor evaluation index system, we needs to consider not only the commercial factors such as quality, price and delivery time, but also the risk factors in a supply chain.

Methods and Models of Vendor Selection

On the methods and models of vendor evaluation, many scholars proposed a number of different evaluation methods and models. To sum up, it is mainly divided into three categories. The first one is the qualitative selection methods [3], for example, the judgment method based on direct experience, the consultations choice method, and so on. The qualitative selection methods are simple and practicable, but they are too subjective and lack of science and rationality, and the most make choices based on experience or some certainty attributes. Therefore, the qualitative methods are gradually replaced by the second method, i.e., quantitative selection methods. Many scholars studied the quantitative selection methods, for example, the benefit-cost analysis method propoed by Federgruen et al. and Hammami et al. , new normalized goal programming model given by Jadidi et al., locally linear neuro-fuzzy model established by Vahdani et al., fuzzy integral-based model established by Liou et al., believable rough set approach presented by Chai et al., integrated data envelopment analysis model established by Toloo et al., Green DEA given by Kumar et al., multi-objective integer linear programming model established by Choudhary et al., two-level Genetic algorithm presented by Aliabadi et al., and so on. The quantitative selection methods have more obvious advantages than the qualitative selection methods, and can solve specific problems under the deterministic environment, but the quantitative selection methods are generally based on deterministic evaluation attributes, and are difficult to quantify some qualitative attributes, and then unable to meet all requirements of processing uncertain information in supply chain environment.

The last one is the combination of quantitative and qualitative methods. For example, Deng et al. proposed a D-AHP method is for the supplier selection problem, which extends the classical analytic hierarchy process (AHP); Shawa et al. used fuzzy AHP and fuzzy multi-objective linear programming in supplier selection for developing low carbon supply chain; Liao et al. presented an integrated fuzzy TOPSIS and MCGP approach to supplier selection in supply chain management; a weighted max–min fuzzy model is developed to handle effectively the vagueness of input data and different weights of criteria in this problem. To handle the subjectivity of decision makers' assessments, a new ranking method on the basis of fuzzy inference system (FIS) is proposed for supplier selection problem. Moreover, a new approach based on Adaptive Neuro-Fuzzy Inference System (ANFIS) is presented to overcome the supplier selection problem. And an integrated approach including fuzzy Technique for Order Preference by Similarity to Ideal Solution (TOPSIS) and a mixed integer linear programming model is developed to select the best supplier in a multi-item/multi-supplier environment. The combination of quantitative and qualitative methods can solve more problems by more scientific and rational way. But how to deal with the uncertainty under the complex and changeable situation in the vendor selection process is further valuable study direction.

Reviews and Perspectives

From the above literature review, we can see that the study of vendor evaluation and selection has been a hot research direction of supply chain management, and the recent research has the following characteristics. Firstly, the evaluation attributes and index system gradually become systematic, diverse and comprehensive. The original single evaluation which only considers the production factors such as quality, price and cost is gradually replaced by the comprehensive evaluation by considering many aspects such as production, service, cooperation, and environmental. So the evaluation index system is more comprehensive, and the evaluation results are more scientific. Secondly, the evaluation methods and models tended to more and more reasonable from the original mainly qualitative judgment, gradually to develop in the direction of the combination of qualitative and quantitative methods. On model applications, it is from using a single model to evaluate, gradually to develop in the direction of the combination evaluation with multiple models. Thirdly, the

evaluation object gradually refined from the original general studies to steer specific industries and specific vendor evaluation. And some studies have proposed different evaluation index systems for different industries and vendors.

However, there are also some disadvantages for existing studies. Firstly, no clear evaluation measurement standards are given for some evaluation attributes. And these attribute data are rarely combined with enterprise's actual demand, so it is difficult to apply in practice. Secondly, the weight determination of evaluation attribute and the evaluation results are over-dependent on mathematical models, so the limitations of the model itself may affect on the accuracy of the evaluation results. Thirdly, in the vendor evaluation, most of the literature does not consider the risk factors in the supply chain environment. Even a few literatures studied on the vendor selection problem in risk management of supply chain, but most still remain in the qualitative analysis. They did not really quantify the risk factors and not consider the quantified risk in the overall level of vendor evaluation. Fourthly, for the quantitative evaluation of vendors in many literatures, the evaluation attributes values are generally given by accurate values.

But in the practical data statistics, due to the complexity of the decision-making system and decision-making environment, and the ambiguity of the human mind, many attribute values are difficult to count by using the accurate numbers such as the reputation of vendors, vendor service level, etc. The evaluation results of these qualitative attributes are given often only in the form of linguistic fuzzy variable (such as better, good, bad or very high, high, low). Also, for instance, in the evaluation of technology risk and management risk for the vendors, the results of risk evaluation are generally given by high risk, low risk, and so on. For the problem of vendor evaluation and selection under mixed data information environment (the real numbers and linguistic fuzzy variable are coexisting), there are few literatures discussed. In addition, the existing procurement mechanisms and evaluation index system are proposed mostly by considering a unique good or multiple indivisible goods. The research on a kind of divisible goods with the characteristic of homogeneousness and continuity is few.

Analyze the combination of national symbols and design aesthetics

Yingyan Chen

School of Arts and Communications ,

Wuhan Polytechnic University, Wuhan, Hubei, 430023, China
252687081@qq.com

Keywords: National symbol; Design aesthetic; Visual form; Change.

Abstract. Current product forms are quietly changing. Duc to the change of consumer personal aesthetic needs, thus causing products need more "non-necessary" functions. Through renovating design concepts by consumer demands, to promote contemporary design pay more attention to the content of visual aesthetics and spiritual cultures. Therefore, contemporary design methods must cater to era development trend, in order to strengthen consumers' experience and emotion recognition for products. In view of this situation, this article from the perspective of national symbolic languages and aesthetic forms to study design methods and innovation concepts, and draw a conclusion.

The situation of contemporary design

China modern design originated from the reform and opening up. Along with the improvement of materials and living standards, Chinese visions and aesthetic also followed developments. Therefore, In this situation, the change of thoughts made contemporary design trend toward User-friendly design.Combining sense and sensibility to meet the functional and aesthetic needs. By product forms, to reflect the organic unity of their internal functions and external visions. Foreign design develop earlier than China. They pay more attention to the design of enterprise culture. And they are to guarantee the basic function of products, but also concern into the products through design culture, which reflects the national languages and aesthetic values.

In the tide of global economic integration, the competitiveness of enterprises are particularly prominent,which reflects in the design is not only the considerations of technical measures, but also the cultural competition.Therefore, some enterprises lack competitiveness in China, in addition to technical reasons, also lack of obvious corporate cultures. Fortunately, there are some enterprises do relatively far sighted, they invite professional design companies to develop the culture of products, or by supporting design competitions, to launch more groups for design service,The benefits of this is to deeper in the inherent culture of products through public power，which makes enterprise to obtain the good development space.

The nationalization of design forms

A kind of cultural form reflected in the product is the reproduction of cultural symbols. Human have been experienced thousands of years of practical activities, dissemination and development of all human civilization have to rely on culture to achieve. The application of cultural symbols is based on nation's cultural systems. Through refining and summarizing the form of nation culture symbols, to have the intrinsic extension in the contemporary design,whichshows a combination of cultural accumulation and technological prowess.

To implement the design form of nationalization, it must reflect ethnic characteristics and style, it has to rely on religious customs, art, genetic characteristics, and other cultural contents. Due to different cultural backgrounds, different districts and nations must have differences in customs, beliefs, hobbies, taboos, color and values, etc. There is such a word to describe the cultural differences of products: Japanese car is a tool, and German car is a machine, while the United Kingdom is art. It shows a national culture form completely reflected by products.Germans is famous for rigorous practical, its products style is simple, precise and machine, which is an objective reflection of national culture; In United Kingdom, its style exudes an elegant and sophisticated,

long-term. It originated from the British people are keen on adhering to traditional culture art. They pay attention to the protection and inheritance of technology and pursuit of perfect quality,which refracts the British national characteristics; Look at Japanese products, Japan is good at learning foreign advanced technology and combining them with national culture, and emphasizing the primacy of practical principles. Their products have a strong sense of national identity and contemporary styles.

Also the other design powers have their own national characteristics,such as Italian design, its products are extremely concise colors and assertive personality, which shows strong Italian style; French design style is often luxury and avant-garde, lead the trend of fashion development. While the five Nordic countries advocate a simple and plain life view , their Scandinavia design styles show the flexible functionalism. It makes national internal spirit and concept into modern design,this is the inevitable result of design nationalization.

In visual forms, a country or nation should combine indigenous aesthetics with modern design style to form an independent design system, which is the development trend of current design.Modern design tends to agree with the national cultures which may derive inspiration from symbols and graphics.Exploring the connotation of national cultures, to find a intersection of national culture and design object, this is the realization of design nationalization.

Famous designer Alan Chan，who is a typical representative of Hong Kong,China. He is good at expressing Oriental culture concept by western design forms, achieve mastery through a comprehensive study. Based on the understanding of national cultures, to borrow western design concept and technique of expression into national languages. It need to achieve a profound understanding and dialectic relationships between cultures.These excellent national cultures are in an open and inclusive environment,which neither blind anti-foreignism, inherits constantly,nor worship foreign countries curries favor with foreign powers.They need to be inherited and innovation, and assimilate the best of foreign culturals into their own national languages. The ultimate goal is to achieve national design, enable national design to have more formidable power and space for development,(as shown in Fig 1).

Fig.1 CocaCola logo in both English

The aesthetic values of national design

National symbols are the legacy of cultural properties after changings of the times, which can express and refer to national cultures' connotations, features, spirits .They have two aspects of value Performances: From intrinsic says, national symbols originated in the life, which contain a wealth emotional life and living state.And nation's spiritual values concentrated in the symbol, have a profound foundation of the people; externally,some outstanding national symbols reflect human universals,and contain the cognitive basis of human.In other words, it is a universal visual language with no national boundaries, any country or nation can through symbols to feel the power of spiritual culture, form a common and shared ideological realm, become a communication link of human consciousness.

Based on the national symbols, to implement design nationalization is actually to grasp national culture symbols, by simplifying language forms to show national emotions, become a window of understanding national customs and aesthetic psychologies. In terms of product culture, we see the external aesthetic forms of products are always the extension of national sentiments, such as German automotive and industrial products which give person a mechanization and solemn feeling, this is the embodiment of national character and express an aesthetic orientation of the German nation. Its products make a profound impression to person. I'm afraid this's the reason of national aesthetic

diversities. Excellent technology makes the public form an awareness of German design through external appearances, which just fill in the blank of other national aesthetics. Therefore, the aesthetic values and spiritual concepts of products can be conveyed through their external images.

China national culture emphasizs “a bad compromise is better than a good lawsuit”. In fact it is a middle course that pursuits natural, humble and suitable styles, while pursuing the spiritual realm of self-reliance. This kind of life aesthetics has positive enlightenment significance to society. In modern materialistic era, people face more and more temptations. If make oriental life aesthetics into design language, it can communicate correct value guidances through products .This is not only to realize the nationalization of material objects, but also a powerful dissemination and promotion of national cultural heritages. And let more people understand national cultures. As shown in Fig 2, this is called a contentment tea-sets. It uses Chinese bamboo as design elements, besides reflecting insulation function, also Cleverly reflects the cultural essence of bamboo. With calm, peaceful and perennial meaning to guide modern people's life attitude, emphasizing ascetic and open-minded spirit. Using oriental philosophy to interpret modern lifestyle and to achieve the perfect unity of both styles and practices.

Fig.2 Contentment tea-sets

Implementing design nationalization, is seeking "to change". There is a word "Any circumstance hitting a limit will begin to change. Change will in turn lead to an unimpeded state, and then lead to continuity". The modern design concept is "to change" in essence. The combination of national symbol and modern design is the conversion mechanism between content and form.This combination is not only to grasp the law of national culture, but is the best representation of aesthetic characteristics. Reconstruction of national symbols is the focus of modern design aesthetics.therefor, symbolic forms must reflect modern people's spiritual pursuit. It is deeply rooted in peoples’ lifestyles and aesthetic practices, which constitutes potential aesthetic qualities and psychological accumulations of the public(as shown in figure 3).

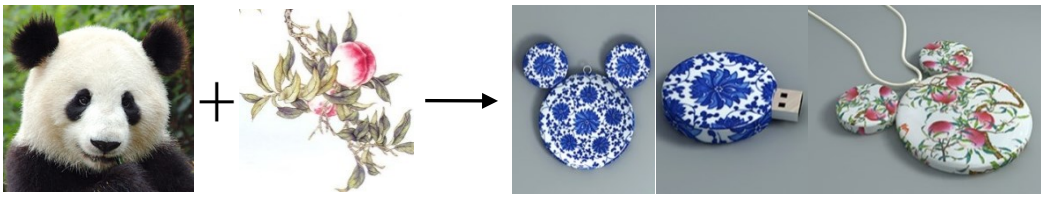

Fig.3 Chinese style U disk

In modern society, symbolic forms are affected and changed by cultural diversities. Only grasping the cultural characteristics of national design accurately and understanding the connotation of design elements correctly, may create a modern aesthetic design (as shown in fig 4). The diversities of design forms, with a different aesthetic consciousness. Whether look at Chinese culture with western values, or on the contrary, our national design should keep its own liberation and beyond. Of course, we can use foreign design forms to disseminate our national aesthetics. With design form to reflect national emotion, is the rea sense of national design internationalization.

Fig.4 Orient Landscape logo

Conclusion

At present, China design industries develop very rapid, but to reach the standard of "designed in China" is still a very long way. So-called "designed in China" is not a formal national design. The key is to figure out what is the cores of China national cultures,and to dig those hidden in the signs which can really reflect the essence of national culture spirits. While grasping the development law of design culture and integrating subtle elements into modern design forms and languages. So it can make national culture spirits and globa design languages together into the mainstream of modern design, this will lead China design has more extensive culturality and nationality.

Keywords: Combined Training; Postgraduate; Game Theory; Mode Selection

Abstract. In this paper, the necessity and significance of combined training of Postgraduate is analyzed. Game rules, strategies and payoffs is introduced about the combined training of Postgraduate. The application problem is researched based on game theory about the mode selection of combined postgraduate.

Introduction

In 2010, the Ministry of Education issued file which is the guiding ideology changed in educational philosophy, training model, reforming the management system, improving training quality, through various forms of cooperation such as schools and enterprises, or industry organizations, in order to actively explore and innovative training model. The Ministry of Education proposed to establish and explore personnel training new mechanism with in personnel training project of serving the special needs of the state in 2011[1].

Combined training of Postgraduate is very important to integrate educational resources of enterprises, universities, and research institutions, which have important practical value to train the innovative talents with founding the problem, solving the questions and independently engaging in research, and to promote technological progress and enhance the competitiveness of enterprises. In recent years, a number of practice researches have explored in aspects of combined training Postgraduate, but it is still in the exploratory stage in the whole. It should be in-depth researched how to create a win-win, sustainable mode of combined training of Postgraduate [2].

This paper will use game theory to analyze the selection problem of combined training mode of Postgraduate , and provide some policy recommendations.

The Basic Concepts of Game Theory

Game theory is how to achieve a set of interdependent strategies and actions interaction between the decision bodies with interest conflict. The basic elements of the game theory include actors, behavior, information, strategies, pay (utility), which are collectively known as the rules of the game. Through all elements of the game theory, the basic model of game theory can be expressed as: G = {P, A, S, I, U}.

(1) Player: refers to the process of the game by choosing their own behavior (or strategy), to maximize their own utility can independently undertake the result of individual decisions. Usually player is represented with i = 1,2, ..., K.

(2) Action: refers to the players in the game during a moment of decision variables. Ai represented by the general behavior of the player for a particular i, with the set of Ai = {ai} which means that all of the activity may be employed.

(3) Information: refers to the knowledge obtained during in the game, such as the characteristics and behavior of the other players. The amount of information of players will have a direct impact on its decision accuracy which is related to the overall success of the game.

(4) Strategy: refers to the players choose their own behavior rules which should take actions during the selection of behavior. Si represents a specific decision by the players of i, Si = {si} represents a collection of all the policy of No. i player. Strategy combination S = (S1, ... Si, ... Sk) is an ordered set of policy of the K game players.

(5) Payoff: also known as Utility, refers to the utility obtained players in a particular combination game strategy. Payoff is the fundamental basis of individual decisions of all players, which is the content really cared by each player. The payoff of No.i player is expressed by ui, u = {u1, u2, ..., un} expressed payoff obtained in a particular game player.

Research on Game Theory of Combined Training of Postgraduate Student

The cooperation bodies of combined training of Postgraduate have businesses, schools and research institutes. Enterprises are market-oriented, the most fundamental purpose is the pursuit of economic interests, so companies will focus on maximizing the economic benefits of cooperation mode selected. Generally, companies are in favor of co-development, so that they can participate in the whole research to improve their Research & Develop capabilities, improving the status of information asymmetry. Schools and research institutes to pursue not only the pursuit of economic interests, also some non-economic benefits, such as academic reputation, etc., schools and scientific research institutes prefer to maintain independence, and therefore schools and research institutes generally biased technology in a collaborative manner, so the choice of the cooperation model is a product of the game between parties of combined training of Postgraduate. Here are some game rules of combined training of postgraduate student, policies and payments

1. Game rules of the combined training of postgraduate student

To clear the Postgraduate in the rules of the game, we need to know the game's players, player action, and these actions will eventually get what kind of results. Companies, universities and research institutions are main bodies in the process of combined training of Postgraduate . In study, in order to simplify the process of game analysis, the two people often are regarded which enterprise is as one game, universities and other research institutions are seen as another game. Action players are to participate in the game at some point of decision variables, in general, ia represents a specific action of the i-th player, iA = {ia} express all actions can be chosen for the collection for No.i player. Action of players may be discrete, or continuous. For example, the mode of choice of combined training of postgraduate student e, action is discrete, the distribution of benefits of action is continuous.

2. Game strategy of the combined training of postgraduate student

The game strategy is the action rules of player in the case of a given set of information, which provides players choose what actions. In general, we use “is” to represent a specific strategy of the No.i player, all strategic collection of the No.i player is a strategic set of the No.i player, denoted iS = {is}, i ∈ N. Each player chose a strategy, all strategies constitute the vector s = (1s, 2s, ..., ns) called a strategy mix, which “is” is a strategic choice of the i-th individual. Strategies and actions described above are talking about here is the same only in a static game model, in other cases they are not the same.

3. Combined training of Postgraduate in game party payoff

Game payoff refers to the utility level obtained by player under the combination of a specific strategy, or the expected utility level obtained by player. Payoff is something that people really care by the game of player. Generally, the payment is a function, and therefore can be said that players pay function “i” is defined in the strategies of combination sets S, the value of a function in the real space R, denoted iU (s). In game theory model, the player's benefit is mutual restraint. The benefit consists two parts in the process of combined training of Postgraduate, one is the overall benefit of cooperation, as well as a member of their own part of benefit between the cooperation the parties, if it is a non-cooperative game, the first consideration between the game is their own party individual benefit, rather than considering the overall benefit. If it is a cooperative game, the first consideration is to maximize the overall benefits of cooperation, and then is allocated to maximize their individual benefit.

Game Analysis of Combined Training Mode of Postgraduate

In recent years, some universities explore the combined training models of postgraduate, which are summarized in the following modes:

1. Training model based on the different stages of cooperation. One is the whole process of cooperation. Business experts are awarded doctoral and master instructor certificate by university, the universities and enterprises participate the whole training process of postgraduate. Another is stage of cooperation. College and business cooperate in aspects of the training postgraduate, mainly in the stage of postgraduate studies and practices stage.

2. Training model depending on the subject of cooperation. One is school-enterprise cooperation model. Another is schools and research institutions cooperation. No matter what form, it has a certain basis.

3. The two models of technology transfer and cooperative development in the model of school-enterprise cooperation.

In this game we have constructed two models: a model of cooperation innovation of school-enterprise player and another model of technology transfer. If technology transfer, assuming that the company pays to the transferee technical university technology transfer fee is D If cooperation innovation, the corporate commitment to technology after the successful development of paid pro rata k commission to universities, colleges upfront technology supply side is I, under normal circumstances (excluding capital costs), after deduction of the subsequent technical development fee income is X, universities do not the relative probability of a successful case under technical development cooperation (willing to technology transfer) of p. Corporate uncooperative (willing to technology transfer), the non-payment of royalties to the university. In this model, we follow the general principles of school-enterprise cooperation: namely, whether to participate in the co-innovation or pure technical trading, technology transfer, colleges and universities as the supply side of technological innovation, companies demand side as the emergence of technological innovations.

Considering the transfer of the latter, university cooperation needed to pay the costs of resources converted into Y, get the game payoff matrix shown in Figure.1.

	Cooperation development	Technology transfer
Cooperation development	(D-I+XK-Y, X-XK-D)	(D-I-S，X-D)
Technology transfer	(D-I+Xpk, Xp-Xkp-D)	(D-I, Xp-D)

Fig.1 Cooperation development and technology transfer game model

Through the above analysis, on the one hand we can motivate a constraint angle design technology transfer mode of R & D compensation, financial external oversight mechanisms to maximize conversion mode, but the general conditions under which the two sides can not achieve the goal; But on the other hand for this article discusses the conversion mode selection, we can choose to co-innovation model, that is, through the development of effective cooperation contract design, the game will be a one-time shift of technology transfer mode multi-stage repeated game, build credibility conversion mechanism between the two sides, which could achieve Pareto improvement.

Conclusion

By studying postgraduate training model, the theoretical knowledge learned in postgraduate has been further consolidated and strengthened, and solving engineering problems by finding corporate laws of science, the practical ability of postgraduate training, pragmatic style and teamwork, in addition to work closely with research technical exchanges institutes, research institutes and

enterprises to follow the mentor and expert learning exchanges and discussion, and further increase their knowledge of Postgraduate, Postgraduate broaden their horizons. Greatly enhance the ability of innovation and academic postgraduate, truly all-round development. Meanwhile, in order to provide Postgraduate in training mode similar reference reform, promote the development of postgraduate education.

The Revelation from MOOCs on Our Country's Remote Education

Wang Junfeng

Distance Education Research Center of Shaanxi Province

Shaanxi Province, Xi'an ,China

wangjynfeng@sina.com

Keywords: MOOCs; Challenges; countermeasure .

Abstract. Since 2012, known as the first year of "massive open online Courses (MOOCs)", its development speed beyond our imagination, only Courses one company registered online learners reached more than 4.1million people (up to July 21, 2013). MOOCs will be bring what challenge for distance education development in China, how to deal with these challenges, is our reality problem need to concerned. We hope through the above question discussion to accelerate the change of distance education in our country, to adapt to the trend of the internationalization of higher education, promoting its healthy development..

Introduction

In 2012 , MOOCs（Massive Online Open Courses）As a new type of higher education online mode gradually entered people's horizons. And formed three online courses teaching website by Coursera，Udacity and edX represented, the resources of website are provided by the world first-class university, offering free online teaching service for global learners, and make the registration at any time, any place can enjoy the best education resources. Coursera, Udacity and edX these three company are called MOOCs "The big three".

MOOCs into China, no doubt that is a big impact to for our existing remote education, we need seriously face it. Such as: Which impact and influence that the rapid rise of the MOOCs brings to our country's higher education, especially in remote education? How the Distance Education should be deal with the challenge of MOOCs? And so on Problems need to think deeply and parsing.

I. The challenge from MOOCs for our remote education

A. The challenges of higher education thoughts

(a) Globalization education thoughts

The impact of MOOCs to China's remote education on the first embodied is globalization education thoughts. In today's information technology changes, MOOCs broke the limitation of national, ethnic, regional, national, provided free Stanford, Harvard, MIT, Cambridge, Oxford and other world-class university's online courses to the entire world, even provided certificate of these courses , the learners in learning knowledge at the same time, also can practice English hearing, improve their English, why not to do it?

And look back on behalf of our country's first-class higher education curriculum standard of national fine course construction, on the one hand, the resource acquisition is difficult, utilization rate is not high, nearly all require registration to browse the resources, is a barrier, compared with countries and about the huge investment in curriculum development, utilization and investment performance is low, contrary to the purpose of the fine course construction; On the other hand even high quality teaching resources, also does not implement free and promote throughout the country, let alone in the global promotion, lack of strategic thinking of the globalization, make our high-quality curriculum "unknown" . [1]

(b) The concept of free learning

In an age of course certificate can be provided free, we still charge according to professional education mode is somewhat outdated? Higher education is training qualified workers and qualified citizen for society, it is a public welfare undertakings, but constantly improve the amount of fees for many families feel difficult. MOOCs appear, it is our hope, she will bring a challenge for the higher education existing "registration fee system of charge before they are learning".[2]

(c) The people-oriented education thought

The curriculum design of MOOCs is learners-centered embody the people-oriented thoughts. And our country's higher education still basically following teachers' leading teaching mode - "teachers speak, the students listen to" very little interaction between teachers and students, teacher leave the classroom in a hurry after class, pay little attention of how much can students mastered. Remote education generally used video lectures, less interactive, learners often study after work, even can't get help from teacher because commuting time limit when they meet difficulties in learning, feel learning is difficult to continue, and finally had to drop out of school.

(d) The education thought of paying equal attention to knowledge and ability

Compared with domestic focus on knowledge learning, MOOCs pay attention to the dual cultivation of student’s knowledge and ability. By setting learning program, make students themselves to form a team, search data, conduct field research, and statistical analysis of survey data and come to the conclusion. This kind of teaching method, not only change the monotony traditional teaching process ,also make the students experience the process of knowledge acquisition, thus cultivating students' ability to obtain information, processing information ability, communication cooperation ability with people, etc., through the learning process all kinds of social practice ability has improved. Review of our higher education, still in imparting knowledge as the main focus.

B. The influence of the way of education

(a) Social learning environment

MOOCs provide social teaching environment, on the one hand, through assignments of some course , learners need in-depth society to carry out the actual research; On the other hand the same region of learners can form a study group, and regularly or aperiodically use cafes, schools and other venues to discuss learning. Our students have to make up for all the "social" lesions after graduation.

(b) The change of teaching means

One is through the virtual experiment and actual practice of research, discussion and other forms of "knowledge" to “acquire knowledge "; Second it is course video clips control within 15 minutes, to achieve fragmentation learning; Third, use depth of education technology, to realize intelligent and personalized management of teaching process.

(c) The High demand of Teacher's role and the professional ability

Teachers embodied in the following: on the one hand, each course teaching tasks are assumed by a teaching team, contains the master teacher, teaching assistant, courseware, etc.; The second is in general the master teachers are outstanding person of the subject, has a high academic reputation, erudite is their common; Third, teachers' teaching design is under a lot of work, for the wonderful

course lay a solid foundation. Compared to our teachers, there is a big gap with MOOCs in breadth and depth in the field of professional knowledge and teaching.

(d) The changes of students learning style

For college students, MOOCs undoubtedly provide a new opportunity and choice, they can accept the teacher's teaching in the school, also can register and login MOOCs. What they faced is no longer the school teachers to teach "unify the whole country", they use MOOCs learning at the same time, also sought to change the traditional learning style they formed over the years.

C. Management

(a) Depend on for-profit and nonprofit company to carry out the network education

MOOCs use the company's operations, Coursera and Udacity is a for-profit company, edX is a for-profit company. The education industry with low barriers to entry, conducive to more companies to join MOOCs camp, compete, and make the learners have more choice, better learning resources and learning support services, namely the learner are the ultimate beneficiaries.

(b) Use course authentication, easy for learner to autonomy and self-control

Course authentication way, require learners to registered in a certain period of time to study, schedule time every week, to spend 2-3 hours to participate in the study. This is equivalent to the learners and the site signed a teaching agreement , the implementation of the agreement, need learners constraints themselves, manage themselves and restrained himself, namely from the traditional learning "heteronomy" into "self-discipline".

(c) The application of technology in the management

MOOCs using information technology to record, store, analysis and processing learner’s data, give corresponding hint for learner's present learning status, and through the analysis of large data on learners' learning behavior, provide empirical support for the teaching reform. MOOCs also use information technology build virtual laboratory, especially pay attention to the interactive courseware, and solves the influence of the "emotional island" phenomenon in network education.

III, The strategy of deal with MOOCs

A. Set up the globalization education thought

To deal with he challenges of global education, can start from the following several aspects: One is to go out. Training excellent teachers Can fluently teaching in English are short of college in our country, through send domestic university outstanding teachers to do high-end visiting scholar at Harvard and Oxford University, in one aspect mastering English teaching at the same time also learn from foreign counterparts in the good teaching ways and methods, improve their teaching level unceasingly.

Second are output courses for free. Output our students like good teacher’s course through MOOCs abroad, we emphasize output courses must teaching and interact in English. The process as seem as our understanding of the first-rate university: at the beginning we known the status of the top universities abroad in Chinese, when require communication after we known, and then began to learn English, in order to facilitate better communication. Both to attract more international students to understand China's universities, understand Chinese culture, it is also a kind of potential recruitment of students propaganda.

Third it is change the passive to active, abandon the narrow intercollegiate ideas, and open the existing teaching resources. Make up our mind to give up the artificial barriers between high quality network courses and universities, remove the password, registration and other restrictions for off-campus learners, open the existing teaching resources, truly free, serving the domestic learners; At the same time also provide English version as much as possible, to facilitate the international learners of non Chinese language learning.

Forth is Introduce a corresponding system, encourage domestic university to participate in international education competition. Through formulate the related policies, encourage universities approved course credits similar to the MOOCs, use course internationalization to promote the pace of internationalization of higher education in our country, through the internationalization of higher education to promote reform in the field of higher education in China. [3]

B. Change the way of teaching

We have been saying for a long time to change the way of teaching, but the effect is difficult to satisfactory, MOOCs give us inspirations are the following:

Change the way of teaching, the first is return to the origin of education, namely the activities of "cultivate people's , teachers should focus on the educates - class students, by building a classroom and extracurricular social learning environment to make student exchange experience for process of" knowledge capture ", instead of the current popular class time "feed in".

Second is put big strength training "masters", promoting "masters" effect ", to carry out other teachers teaching way transformation by carry out bilingual teaching "masters". Globalization of education, requirements "teacher" have the strategic vision of globalization, globalization of teaching ability and professional quality, to cultivate the talents of globalization.

Three is change the existing teaching mode, change personal teaching to team collaboration, set the wisdom of the collective to carry out course teaching research, guide students to change learning style at the same time, improve the teaching results. [4]

C From knowledge-transference to ability training

For a long time, we accepted the education of students from kindergarten to university is the students listen to the teacher "the knowledge feed in" mode, and the evaluation is focused on the master degree of knowledge, less attention to the formation of student ability, lots of "high score low-energy" phenomenon. In MOOCs era learner’s ability training should focus on the following aspects:

One is the cultivation of learners' learning ability. In reality we often found there are many of students at ordinary times very hard, but learning result is bad. Much of these student is not master the suitable learning method for their own, namely the ability to learn, usually wasted effort. Such as English learning through more than 10 years in primary school to university study, we still can't communicate with foreigners freely, of cause there are problems such as culture, teaching methods, but one of the main reasons is teacher didn't pay enough attention focus on students' English learning ability training. [5]

The second is the cultivation of the learners' self-control and self-discipline. Learning is learner’s personal things. But we have stressed discipline education from primary school to university, and not pay enough attention on learners' self-awareness, self-management and self-discipline level; we pay too much attention to external factors, while neglecting the learners' initiative. Use learner's self responsibility consciousness education to cultivate their autonomous self-discipline, and self management.

Three is the cultivation of the learners' communication ability. Communication ability has always been a "short board" in our education. In traditional classroom teachers' teaching and students have no chance to express their opinions, the interaction between teachers and students is extremely limited, cause lack of communication ability. Create conditions to carry out the discussion-based

teaching, make each learner to actively participate in class interaction, improve their communication ability in learning.

D. Simplified management, pay attention to technology application

Simplify the management of higher education, to relax the admittance threshold of higher education, attract the foreign high-quality education resources into China, and then promote the development of higher education in China.

Compared with MOOCs, remote education technology is not backward in our country, but for the depth of the technical application we still has the very big gap, such as through to the learners' big data processing and analysis, put forward the corresponding countermeasures and Suggestions for teaching, etc., we're in the shallow of data processing application, lack of mining and analysis. Our reality choice is pay attention to the depth of the education technology application, introduction of large data statistics and analysis talents to join the teaching team, improving the teaching performance.

Abstract. During the rapid development of information technology, the global widespread information wave has come. Exploring the intelligent information technology on the mechanism of the urban space helps to drive targeted policy-making about city planning. In this paper, taking cities in Guangdong as samples , we firstly discuss about the relationship between the level of information technology and personal travel. Primarily, analysis the fitting relationship between information flow and public traffic flow of the 21 cities at a certain time. Secondly, investigate how information technology influences the residents' travel at the micro level by means of questionnaire surveys. The study shows that internet information has a significant promoting effect on the residents' travel of general cities, but a substitution effect in a few large cities which has highly developed service sector.

1. Introduction

Traffic is the main artery to promote urban function in modern times, which has been put forward by Athens Charter. The rise of information technology undoubtedly has great significance in urban traffic development. Transportation and information has become topics in recent years, and are often classified into the same category. They have closet contacts and influence to each other, and play common role in social and economic development at the same time.

Many scholars have carried out considerable research on how information technology affects the city traffic, Graham, Marvin (1996) summed it up in four effects - *physical developmental effects*, *substitution effects*, *generation effects* and *enhancement effects*.[1] The substitution effect refers to the development of communication technology that can overcome the obstacles of interpersonal communication. Gaspar, Glaeser (1998) thought information technology is not only a supplementary for face-to-face communication but also a substitution.[2] Generally, it weakens the urban agglomeration.[3,4](Negroponte, 1995; Sridhar, Sridhar 2003) In other similar empirical study, Gothoskar, Sharma (2000), Ng, Jin (2000) and other scholars found that due to the development of information, technology switching of information space increases the possibility of multi-location work, and then information technology leads to spatial dispersion and reduces the demand of travel.[5,6]

Other scholars focused on the impact of information technology on different traffic streams. Typically, Golob and Regan (2001)argued that personal travel behavior which impacted by electronic information could reduce to *consumer electronic commerce*, *other telesevices*, *flexible working arrangements*, *self-employment*, *contingent*, *part-time working arrangements*, *mobile working* and *ATIS for vehicles*.[7]They also reduce the commercial activities under the influence of travel information flow to *business-to-business e-commerce*, *structural changes in the freight transportation*, *logistics industry* and *ATIS for commercial vehicles*.[7]

In this respect, there are many studies about the impact of Electronic Commerce on traffic (Mokhtarian, 2002, Visser, Lanzendorf, 2004).[8,9] For instance, Weltevreden, Rotem-Mindali (2008) pointed out that, the informatization in B2C (businesses-to-consumer e-commerce) will reduce the

traffic demand while the informatization in C2C(consumer-to-consumer e-commerce) may make the travel behavior more likely to occur.[10] Similarly, face – to - face communication will still play an irreplaceable role in the advanced producer service sector due to the demand of tacit knowledge. IT substantially stimulated this kind of traffic demand and has improved intercity traffic and the demand of informational linkage. Thereby, the management and control of division of global industry can be realized. This is also the objective basis of the formation of global cities network.[11,12](Sasssen，2001；Taylor, Ni and Derudder, 2009)

Some scholars believe that although the electronic communication has greatly expanded the frequency and intensity of non-local connection, it did not lead the local communication to be meaningless. Instead, it greatly enhances the diversified contact of local people (Zook, 2004).[13] In these years, some scholars such as Axhausen (2008), Carrasco, Hogan (2008), have focused on the social activities and travel, which provides a new perspective for different types of traffic flow research under IT.[13,14,15]

In the related research in China, meanwhile, Hong Zhen(2000) and other scholars have already done research about the relation between information technology and transportation thoroughly in an early time.[16]Zi Lu and Huiqiao Zhang(2003) analyzed the positive impacts on the urban spatial structure through the organization of traffic flow, that caused by the approved traffic directing system in Shijiazhuang.[17] Referring to the web services statistics, Shifeng Wu and ZiLu(2007) created the criteria of realistic traffic flow, and calculated the substitution impacts which the internet information movement has exerted on realistic traffic flow.[18]After studying the intelligent community in Hangzhou, Ruiling Han, Qiuluan Zhang and Zi Lu(2010) discovered that the virtual community does affect the resident behaviors in reality; the intelligence of internet plays the greatest leading role. The homogenization of affected population is a prominent feature when virtual community's information flow guides the choices of residents.[19]Based on these summary of relationship between information technology and transportation, Miaoxi Zhao (2014) puts forward his expectation about the use of intelligent transportation in the situation of smart cities.[20]

According to the evidence discussed above, some studies have not come to a clear conclusion. What's more, comparison between different cities is inadequate in existing studies; No study was done about relation between information technology and travel behavior from both macro and micro aspects. Therefore, in order to have a further study about the spatial mechanism of information technology, it is important to choose representative region, and to compare the relationship between information technology level and prohibition of commuting.

2. Research Design

2.1research object

In the 21st century, the process of Chinese urbanization and mechanization is continually accelerating. From 2000 to 2013, Chinese urbanization rate increased from 36.2% up to 53.7% and the average annual growth was about 1.15%. The urban population grew from 460 million to 730 million, making a net growth of 270 million. Nevertheless, the possessing capacity of vehicles in first-tier cities like Beijing, Shanghai, Guangzhou, Chengdu, Hangzhou, Shenzhen, has exceeded one million. To regional economy, it becomes a core issue that how to allocate the limited resources properly to make urban traffic function efficiently when lacking public hardware facilities. However, how information technology affects urban resident trip remains to be further investigated. Therefore, 21 cities in Guangdong province are chosen as survey targets.

In China, Guangdong province is the most prosperous one in economy. However, the socioeconomic discrepancy between the different internal regions still exists. Guangzhou and Shenzhen have developed into very significant node cities in the global economy, and some peripheral regions underdeveloped still exist there.

Thus the uneven urban development helps to compare the causality of IT and passenger transport better, and we can achieve the purpose of this research, clarifying the spatial mechanism of information technology by exploring residents-travel characteristics for different cities in

Guangdong Province, and analyzing the specific impact on residents travel caused by ITC more deeply.

2.2 research methods

The empirical study consists of a regional comparison at macro level and a questionnaire survey at micro level. Firstly, we use 21 prefecture-level of Guangdong as targets for comparison to explore the fitting function relationship between information technology level and transportation; secondly, through questionnaire study on how IT influences transportation, and discusses how information technology influences the decision of residents travel from a microscopic angle.

3. The overall level of regional comparison

This study first compares the relationship between internet technology level and traffic volume among different cities by using analysis of variance.

For a polynomial fitting, known set of points with n（i_a， $f_1(i_a)$），a=1,2,3…, find m times （$m<n$） polynomial $f_m(i)$:

$$f_m(a)=k_0+k_1 i+k_2 i^2+\ldots k_m i^m \quad (1)$$

And figure out the Residual sum of squares and select polynomial. And Q_m is the minimum value for the residual sum. Make significant test on polynomialf_m.

In the process of quantifying the indicators of informatization, LiuyuLu(2002) pointed out that the application of internet technology is an important mark to measure the degree of information, but he didn't have the exact statistics, so we replace it with other related indicators.[21] The total number of mails, the number of newspapers and periodicals, the total number of the total number of mobile phone users, the total number of expressage as well as the total number of telephone users have been selected in this article.

Arranging the trips, people will get the information in advance to make travel more effective. However, the level of information technology varies in different cities of Guangdong province, with the Pearl River Delta region occupying a geographic advantage, while access and use of information in developed cities such as Guangzhou, Shenzhen are more fully. These cities have a higher level of information technology; while western northern region economy is relatively backward, experiencing serious brain drain, which results in generally low level of information.

At the same time, levels of economic development and the impact of geographic location varies in different regions of Guangdong Province. The urban traffic as the Guangzhou-Shenzhen regional transport get a good head, while that in remote areas develops still slowly. Taking account of the practical problems, select the amount of municipal public transport as a measure of urban transport. Let's take 2012 Guangdong Statistical Yearbook tables 14-19 steam tram and public taxi data to calculate the per capita amount of public transportation as a measure of traffic travel. Organizing the data above, evaluate the logarithm of the amount of information technology level standards and per capita amount of public transportation to get data in Table 1.

Table1: Standard date of 21 cities of Guangdong Province in 2012

City	Information Technology Level	Per Capita Amount of Public Transportation
Shanwei	*4.22*	*5.85*
Yunfu	*5.07*	*11.14*
Yangjiang	*6.05*	*8.52*
Chaozhou	*7.12*	*8.66*
Heyuan	*7.17*	*19.33*
Shaoguan	*7.89*	*33.61*
Jieyang	*8.39*	*4.27*
Zhaoqin	*8.59*	*30.08*
Meizhou	*8.73*	*8.28*
Qingyuan	*8.98*	*26.32*
Maoming	*10.42*	*7.39*

Zhanjiang	*11.14*	*31.00*
Zhuhai	*12.48*	*229.49*
Shantou	*15.12*	*27.19*
Huizhou	*15.36*	*58.60*
Zhongshan	*15.91*	*90.21*
Jiangmen	*19.57*	*39.27*
Fuoshan	*40.17*	*87.57*
Donguan	*45.34*	*89.13*
Shenzhen	*79.35*	*255.13*
Guangzhou	*99.21*	*266.99*

Table 1 presents observable liner relationship between information technology level and traffic volume. resident population in Zhuhai remains only 1.58 million, less than 1/6 of Guangzhou . It gives an abnormal high level to public traffic of per capita of Zhuhai, affecting the overall results of the analysis of data, so we delete the sample of Zhuhai in the end.

Based on the table fitting function $T(i)$ at different polynomial variance analysis as shown in Table 2.

Table 2：Analysis of variance under different number of polynomial

n	*T(i')*	R^2
1	$y = 2.8284i - 4.5062$	*0.933*
2	$y = 0.0051i^2 + 2.3506i + 0.1313$	*0.935*
3	$y = -0.0002i^3 + 0.0399i^2 + 1.099i + 8.6715$	*0.937*

As in Table 2, the cubic polynomial $y= -0.0002i^3 + 0.0399i^2 + 1.099i + 8.6715$ fits the facts most. At this time $T(i)$ basically reflects the relationship between Per Capita Amount of Public Transportation and Information Technology Level. Study also uses the coupling relationship between the development of urban transportation and information technology development, as showed in Fig.1.

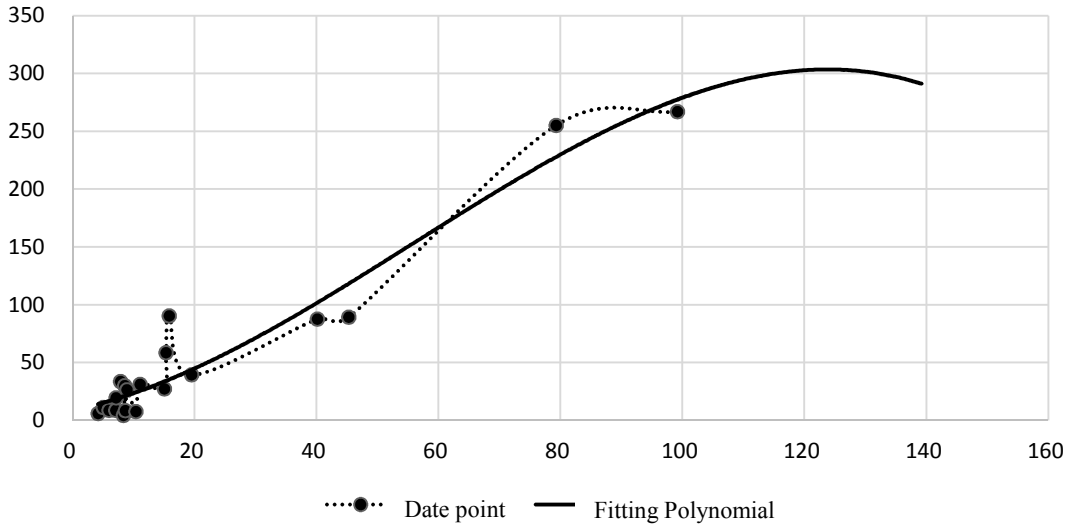

Figure 1: The Impact of Information Technology on Regional Traffic Travel Trends

Table 2 illustrates that traffic in the cities such as Shanwei, Jieyang are at very low levels.With the lower level of ITC consuming, their transport trips are still increasing. Obviously, in the early stages of urban development, information technology facilitates communication among residents. Individuals using the obtained information for more efficient travel, increases travel efficiency since the communication time is reduced and the cost is greatly increased.

However, when the level of IT reaching a certain level this marginal benefit will be reduced, resulting in a substitution effect proposed by Graham, Marvin (1996).[1]In the developed cities such as Guangzhou, Shenzhen, with wider use of information technology, internet mobile devices, and

social networks allow people to talk without meeting face to face. "Web conferencing", "e-learning" and "home office" and other way of e-life have been more accepted by people, meanwhile the rise of online shopping meets the needs of contemporary society "home" life crowd.

Nowadays, people can stay at Homes to complete the work or study at the same time without losing contact with the outside world life. As a result, people will greatly reduce travel. With more advanced information technology used in residents' daily life, people will choose the way to get non- travel resources they need, thus greatly reducing the amount of traffic. But as the study has reviewed, differences on the degree of information region, education level and those of individuals can be seen visually different a lot.

To summer up, in a city there exists promoting and substitution effects between information technology and transport. With the restricts of local factors such as the level of development in different regions, these two effects trades off and takes turns., and ultimately show the total effects of promoting or substitution.

4. Exploration of micro-level mechanism

4.1Travel distance under the impact of Information Technology

To explore the mechanism on the relationship between information consuming and traveling, respondents in the questionnaire study are classified into groups by the difference of the time using Internet every day. And a random survey was carried out in suitable areas. The data of the answers on the Internet, electronic equipment and transportation are organized to analysis in quantity and nature, which verifies whether the impact of the level of information technology on urban traffic flow meets the aforementioned mathematical models. Shunde District of Foshan city is selected as the study area, which has a resident population of 195.53million.

The questionnaire distributed in 2012, mainly related to the Internet using, commuting time, transportation modes, transportation costs, traffic destination, leisure travel time at weekend, content of traffic information accessing and other issues. According to the feedback, information technology level is characterized by the time they surf the net each day. Traveling behavior includes many factors such as traffic time, traffic consumption, travel distance etc. Four variables characterizing personal trip, include home time in weekdays, monthly travel costs, luxury shopping places, and leisure trip time at weekends. By studying the relationship between variables of IT and transportation to explore the impact of information technology on the traffic flow in the region.

The quantitative relationship was studied by Binary Logistic regression analysis.

Logistic regression model is often used to study the relationships between response variables and other independent variables. The two results of binary response variables Y are denoted by 1 and 2. Four independent variables affect the response variable Y is denoted by X_1, X_2, X_3, X_4. The conditional probability of "Case 1" under the influence of the 4 independent variables is donated by$p = P(Y = 1|X_1,\ X_2,\ X_3,\ X_4)$. The Logistic regression model is denoted as

$$p = \frac{\exp(\beta_0 + \beta_1 X_1 + \beta_2 X_2 + \beta_3 X_3 + \beta_4 X_4)}{1 + \exp(\beta_0 + \beta_1 X_1 + \beta_2 X_2 + \beta_3 X_3 + \beta_4 X_4)} \quad (2)$$

In the formula above, β_0 is the constant term, and $\beta_1, \beta_2, \beta_3, \beta_4$ are called regression coefficients in Logistic regression model. Home time in weekdays, the monthly cost of personal trip, distance to luxury shopping places and single-trip time of leisure travel at weekends are selected as independent variables. Whether surfing the net more than two hours a day sever as dependent variable. "1" represents surfing the net less than or equal to two hours, "2" represents surfing the internet more than two hours.

Table 3. The letters of corresponding variables

Variable	Whether surfing the net more than two hours	Monthly transportation costs	Home time	Luxury shopping places	Leisure trip time at weekends	Constant
Corresponding letters	Y	X_1	X_2	X_3	X_4	β_0

Table 4. Output of binary Logistic regression analysis

		Coefficient	Sig.
Step 1	X_1	0.162	0.000
	X_2	-0.12 0	0.000
	X_3	0.193	0.000
	X_4	0.001	0.785
	β_0	-0.532	0.010
Step 2	X_1	0.164	0.000
	X_2	-0.12 0	0.000
	X_3	0.194	0.000
	β_0	-0.52 0	0.010

From the table above, single-trip time of leisure travel at weekends is excluded from the regression equation. Home time on weekdays, the monthly cost of personal trip and distance to luxury shopping place are retained, moreover their values of P is less than 0.05. The coefficient of transport costs, distance to luxury shopping places is positive, while the coefficient of home time is negative, which indicates that increasing of the time for surfing the net, monthly transport costs and the distance to luxury shopping place will increase, while home time will decrease (it means commuting time will rise).

Comparing with the group of less Internet time, people with more Internet time would spend more time and expense on commuting, and incline more to travel to faraway places as luxury shopping places. A conclusion can be drew that information technology will enhance the probability of travelling in various aspects (travel time, travel costs, travel distance, etc.)

4.2 Information technology embodied in the transportation

The aforementioned analysis indicates that level of information technology will promote transportation. The following part will explore the inner reason of this situation from acquiring traffic information. Traffic information will directly affect the transportation modes and willingness to travel. The reason why IT can promote transportation to a certain extent, may be that IT provides a relatively adequate information for people to travel, increasing the willingness and feasibility of people to travel. To determine this assumption, the Internet time of respondents (≤2hs/per day, >2hs/ per day) characterize the frequency of using IT, when " traffic information hope to obtain before traveling " sever as the test variables, to study the relationship between the frequency of using information technologies and ways to obtain traffic information as well as content. First the T-test is used to test the significant of Internet time and seven variables about traffic information obtaining.

Table 5. Output of T-test

		Levene test of variance equation	T-test of mean equation
		Sig.	Sig. (Bilateral)
Travel time to destinations	Equal variances assumed	0.000	0.000
	Equal variances not assumed		0.000
Road toll	Equal variances assumed	0.001	0.095
	Equal variances not assumed		0.096
Map and guidance	Equal variances assumed	0.000	0.000
	Equal variances not assumed		0.000
Weather	Equal variances assumed	0.921	0.128
	Equal variances not assumed		0.128
Real-time traffic situation	Equal variances assumed	0.261	0.575
	Equal variances not assumed		0.575
Parking lots	Equal variances assumed	0.001	0.084

information	Equal variances not assumed		0.086
Others traffic	Equal variances assumed	0.000	0.023
information	Equal variances not assumed		0.021

From the t-test results: there is a significant between characterization of traffic information and Internet time, consistent with the standard allowing a 5% chance of errors (except for the weather and road conditions in real time travel).

The respondents are also divided into two groups "two hours or less online" and "more than two hours online", to calculate the percentage of five variables in the two groups. Study the difference of percentage of the same variable in two groups, to find the impact of using IT on acquiring traffic information.

Table 6. Percentages of traffic information hope to acquire before travel in two groups

Information hope to get		Two hours or less online (%)	When the Internet grew up in two hours (%)
Weather	No	48.2	51.9
	Yes	51.8	48.1
Real-time traffic	No	63.2	64.5
	Yes	36.8	35.5
The time to reach destinations	No	49.5	38.6
	Yes	50.5	61.4
Road toll	No	76.0	72.5
	Yes	24.0	27.5
Map and guidance	No	50.1	37.9
	Yes	49.9	62.1
Parking Information	No	88.0	85.2
	Yes	12.0	14.8
Other Information	No	88.4	91.8
	Yes	11.6	8.2

From the table above, people who spend more time on the net have a stronger willingness to require traffic information than those spend less time on the net, such as time to reach destinations, road toll, map and guidance, parking information and other information. According to T-test, it is known that how long one spends on the internet is not obviously relative to willingness of requiring information about weather and real-time traffic. It is because such two kinds of information can be obtained easily and adequately form traditional media, such as television, newspaper and radio, instead of Internet. However, acquiring other four kinds of traffic information depends on the Internet instead of traditional media.

From the analysis of the relationship between IT using and traffic time, cost, distance, it is known that one of the reason why IT is able to promote transportation is that IT can bring the traffic information which can't be required from traditional media easily or adequately. It increases the willingness of searching traffic information and improves the feasibility of travel.

Shunde area belongs to the typical area of "IT level promotes traffic flow" in the aforementioned mathematical model. Therefore, the mathematical model of the coupling relationship between information technology level and the probability of travelling accords with the empirical results.

5. Summary

This paper uses statistical methods for data processing to obtain the level of information consuming and urban transport travel metrics, least squares polynomial fitting and analysis of variance for the two mathematical models were fitted to explore these the relationship in the cities

of Guangdong Province. By analyzing the functional relation, the role of the information for the residents of the city's traffic travel in general plays a significant role in promoting, but in a small number of highly developed cites with advance service sector there are certain metropolitan substitution effect. The followed data based on survey reveals the mechanism of relationship between information technologies and prohibit of travel choices.

To illustrate, in the mathematical model of the process, we set a pre-condition of the hypothesis, the traffic travel decisions and IT assumes a single linear causality, but it can be further explored in future studies of the process of decision-making mechanism to travel under the influence of multiple factors, which will provide specific policy recommendations for transportation planning practices.

The research of building CAI table tennis teaching system

Zhang Baowei

Lixin University of Commerce, West Zhongshan Road.2230, 200235 Shanghai, China
zhangbaowei.66@163.com

Keywords: CAI multimedia courseware table tennis

Abstract: The CAI technology and Multimedia technology applied in physical teaching can improve the teaching efficiency, arouse the students' interest in learning, improve teachers' teaching ability, promote students' learning enthusiasm and accelerate the update speed of knowledge. The basic program of multimedia courseware development is the courseware topic .design, writing and operation. In education of sports theory teaching, PE teachers using the image and video or other functions of computers to create a variety of situations, improve the theoretical knowledge of visual in practical application. Students can understand theory on the courses more deeply.

1 Preface

Table tennis is a project which mainly requires skills. It includes speed, rotation, arc, placement, rhythm and adjustment. Table tennis has the characteristics of speed and rotation .As a representative of modern information technology of multimedia---CAI (Computer Assisted Instruction). Its novelty and diversity is vital to stimulate interest in learning. CAI courseware set text image, animation, voice and video as a whole to form teaching system through processing. In table tennis teaching, teachers take students' attention to the teaching content through visual and hearing. Create pleasant situation and motivate the students to learn. It has important significant to efficiently complete the study task.

2 The research method

2.1 The literature method: Access to literature and books about computer technology. Access to literature and books about table tennis.

2.2 Multimedia production method. Collect text, picture and video information about the rules of table tennis match PP widely and process it .Use Word, Photoshop, Movie Maker, Author ware etc. for the production of multimedia courseware.

2.3 Expert evaluation method: Interview and communicate with other institute table tennis teachers and computer science experts before making courseware .Consult experts as the reform of the teaching method and the understanding of table tennis' concept and the difficult of the research and application of the courseware. Provide advice and guidance to the research of this text. The course focuses on training to seeking problems in the real world and knowing how to solve problems.

2.4 Questionnaire survey method

Project questionnaire about classified the mistake in table tennis teaching .Investigate the national table tennis teaching experts and professors.

3 Design and analysis of courseware

3.1 Analysis of the courseware requirements.

Multimedia courseware mainly used for the students in table tennis general class auxiliary teaching .Teachers can make multimedia courseware presentation in class while students can learn by themselves through the courseware .In a questionnaire on students learn., students have access to media teaching method. The main teaching method is by slide and videos mainly in theory class. Students feel more vivid after watch it, willing to accept multimedia CAI courseware in sports technology.

3.2 The guiding ideology of courseware design.

Changing the teaching method is for the purpose to improve the quality of teaching. This courseware guided by the modern education thought. This courseware based on teaching book <the rules of table tennis match>. This courseware combined with modern education technology and traditional teaching methods. Build a new teaching type about the rules of table tennis. Give students a learning environment combined with vivid and visual through the application of courseware. Achieve the goal of reforming and improving the teaching method and objective .Improving the teaching efficiency and quality. What teachers teaching (to students) and how teachers teaching (through what way to teach) is the mainly problem in multimedia teaching. The category, number and the intension of information and the transmission media all affect the process of teaching and development in learning. Different learning stages are based on the basis of previous learning phase. It is not a simple repeat process, but a development of the sublimation for students. So, it is our basic guiding ideology that how to make difficult textbook to be suitable for mental ability development. Transmitting and speeding the process to students effectively through a variety of media

3.3The goal of design courseware

Teaching goal is the basis of all teaching activities. Grasping the teaching goal influence the choice of teaching media and the design of teaching unit. CAI courseware in design should pay attention to the teaching goal of guiding role. According to the content and requirement of <the table tennis match rules>, the CAI courseware 'goal is: Give students a learning environment combined with vivid and visual through the application of courseware. Make full use of the courseware guidance, demonstration and the interactive practice function. In order to make students master the content and the connotation of <the table tennis match rules>.Improving students' learning interest, efficiency and the practical ability.

3.4 The principle of courseware design

The general principle: This courseware produced by Macromedia Authorware7.0 platform. After completed, files are packaged to generate in the form of an application suffixed by '.exe', and it can be used in any computer without the software, which is fully based on the general principle.

The scientific principle: It mainly displays in the scientific description of the concept, the accurate statement of the problem and the correctness of the reference data. This courseware ensures that the rules of the original content remains the same in the production process .And to explain the rules by texts and graphics, through access to various data, it makes every effort to make the courseware more normative and accurate.

The principle of elicitation: The CIA courseware in the design and production should focus on the teaching objectives, and is teacher-led, student-centered. Through the multimedia CAI courseware provides vivid, intuitive materials, to stimulate students' association, arouse learners' knowledge in long-term memory, their experience so as to assimilate new knowledge, to cultivate learners' innovation consciousness. Therefore, the design of CAI courseware on the choice of content and form also follows the principle of inspiration innovation.

3.5 Courseware platform

PE teacher's choice of tools to make courseware are various, such as PowerPoint, Authorware7.0, Director Flash. This courseware is based on Authorware7.0 as platform. Macromedia Authorware7.0 is an interactive multimedia authoring tool based on flow charts. With its advanced, rich visual media production solution, elements like pictures, animations, text and films can be fused into the field of multimedia applications. Furthermore, some pictures will use Photoshop for partial treatment, to produce more professional multimedia courseware.

3.6 The script writing of a courseware

Before making a courseware the primary task is to write a script that is the core and main basis of a courseware, and will have a direct impact on production quality of the courseware. The courseware based primarily on "(2006)," Table Tennis Competition Rules "compiled by Chinese Ping Pong Association, and also it keeps an eye on the latest version of other rules and some constantly

updated, revised books about tennis rules .I also collected some teaching experience from table tennis experts in our college, to strive to make writing scripts with strong authority and persuasive.

4 The analysis of basic structure of teaching material

Bruner subject structure points out that no matter what we teach it is important to make students understand the basic structure of the subject. Once students understand that and they can extrapolate. Therefore, when we study the teaching method, the key is to study the content, structure, logical relationship of the teaching material and students' learning methods. Through various media means, in order to be able to fully reflect the teaching material content in the limited teaching space, on the media design, first of all, not according to the order and structures of teaching materials to produce on a variety of media, but in the study, on the basis of the teaching material content, set up the logical structure of knowledge, in order to certain the key knowledge and learning levels of each chapter, and then we can choose the media. Second, based on the teaching material content and the logic structure of knowledge, we can increase the vivid picture, different angles of animations, etc., to rich the knowledge of classroom teaching, to build a good atmosphere of learning, and to increase understanding of the teaching material content.

5 Courseware development ideas

5.1 Basic principles of courseware design:

1) scientific2) universality 3) controllability 4) practicality

5.2 Courseware teaching objectives:

Give students a learning environment combined with vivid and visual through the application of courseware. Full use of computer graphics, images, animations and other features that enables students to develop the right concept of the action of Tennis Forehand Fast Break, to master the main points of the teaching content, to improve students' learning efficiency and to broaden their knowledge.

5.3The production of the courseware materials

5.3.1The production of the text:

Making the text includes two aspects. The first is WordArt production in interface part. It is achieved through Word and Photoshop, The second is the production of context, which is use Word for production.

5.3.2 Image production:

Most images in the courseware are formed by the scanner, and then processed by Photoshop. But some images are produced by "Brush" software and then processed according to Photoshop.

5.3.3Animation production:

Animation production is the most important and most difficult step in the process of making a CAI courseware about Tennis Forehand Fast-Break. In this case, the animation means using POSER4.0 animation software imitate the movement on computer. Because most of the courseware demonstrations are done by the animation, its quality will directly affect the quality of the courseware. The overall courseware production is achieved by Authorware7.0.

6 Conclusions

6.1 The design and manufacture of multimedia teaching should highlight the characteristics of the teaching material content, and to solve the difficulty in the routine teaching as the development of multimedia.

6.2 Multimedia table tennis teaching highlights the importance of feedbacks, enlarges the way of teaching information’s transmission, enriches the students' learning activities, and makes students learn independently.

Keywords: BIM;BIM high-end talent;Colleges and universities;Communication platform

Abstract: With the construction of "The 12th Five-year Plan" put BIM (building information model)On the agenda,the development of construction industry is more and more inseparable from the BIM high-end talent.Based on the analysis of the development of BIM at home and abroad and applications in the construction industry and the present situation of fostering BIM high-end talent, on the basis of the fuzzy comprehensive evaluation model based on AHP is established. Discuss the bottleneck of BIM high-end talent cultivation, and find out the key factors ,meanwhile put forward countermeasures,which provides scientific basis for fostering BIM high-end talents.

Introduction

What BIM will cause a technology revolution in the construction industry has been unstoppable trend.At present, in our country, to vigorously promote BIM technology is very timely and necessary.But based on the development of BIM in China at an early stage, technology and theory is not yet mature, which extreme lack of high-end talent plus construction industry.High-end talent fostering BIM is vigorously carry out the ministry of education on deepening the reform of personnel training mode, and improve the systems and mechanisms to improve the quality of teaching.In-depth implementation of the teaching quality and teaching reform project in colleges and universities, the employment as the guidance of the support of the reform and construction of colleges and universities.BIM construction and practice of teaching idea at the same time, to carry out the training curriculum system, cultivating both conform to the requirements of the construction industry development and talents of integrating with social practice, for the BIM high-end talent shortage and college students difficult employment problem put forward an effective solution.

The current situation of the development of BIM and it's application in the construction industry

The foreign current situation of the development of BIM
Abroad, development of BIM technology is already very mature.At present, the study of the theory of the BIM technology is ripe.It is rich practical experience in developed countries and wide application range.Such as the United States, Japan, Singapore and other developed countries It's worth noting that the government agencies, private enterprises in various fields such as construction industry and academia is widely involved in research of BIM technology.
Domestic development status of BIM
In our country, the development of BIM is still in the primary exploring stage.BIM technology in our country's construction industry is mainly used in engineering design, consultancy and training institutions.With the popularity of BIM technology application, the department of housing and urban-rural development put forward, in the "twelfth five-year" period, the basic elements of a construction enterprise information systems, to popularize and apply to speed up the building information model (BIM),and web-based collaborative work, etc. New technology application in the engineering, promote the construction of the information standard, carry out the research and application of BIM technology, and promote the BIM technology application extends from the design phase to construction phase.

The application of BIM in construction industry
The rapid development of BIM and its own technical advantages, which determines its will be applied to all aspects of the construction industry, including the owners and developers to design, construction, cost, purchasing, marketing, management scope;Design unit building, structure, water supply and drainage, HVAC, electrical, fire protection, design of the technical and economic activity;Construction enterprise project management, engineering cost, construction plan, construction technology, operational property agency operations, maintenance, and all kinds of activities will involve the application of BIM technology.

The current situation of talents fostering BIM

BIM began to be China's colleges and universities focus on research in 2006 , but in this short eight years has also made gratifying achievements.
First of all, in the early period of the colleges and universities to establish associated with BIM software courses.According to the latest statistics in 2013, 85% of colleges and universities have courses in CAD.With the development of BIM, most colleges and universities for engineering construction (especially to the characteristics of colleges and universities) has set up a 3 d software similar to that of the BIM course, such as Revit software.Some universities have courses in BIM software.

Secondly, colleges and universities set up scientific research institutions.Some universities have established BIM research and research centers. A growing number of doctor, master choose BIM technology as a research direction, which promote the development of BIM technology in our country.
Third, colleges and universities actively take part in the national colleges and universities BIM software building information model contest.With the development of BIM technology, colleges and universities participate in this contest in the constantly expanding.The number form 70 universities to the 147 universities .The fifth session of the national colleges and universities , cup contest of BIM software modeling start-up and format the workshop ended successfully.According to statistics, there are 248 colleges and universities to participate in the competition.

The bottleneck of BIM high-end talent in college education

Analyze the bottleneck of BIM high-end talent
With gradually promotion of BIM technology and further to speed up the pace of construction industry fields as well as the society and the construction industry for BIM talent demand is increasing, the BIM high-end talent cultivation reforms in colleges is inevitable.But there exists a series of obstacles in the process of the implementation of the promotion.This article selects the BIM technology experts to hinder the implementation of BIM factors discussed analysis of high-end talent training.After discussion experts divided it into four categories: technical factors, economic factors, operational factors, motivation factors.
The college education of BIM bottleneck of high-end talent evaluation index is established
Through implementation of BIM high-end talent cultivation in colleges and universities ,it established the evaluation index system of high-end talent cultivation in colleges and universities implement BIM bottleneck.The system includes four indicators: technical factors, economic factors, operational factors, motivation factors.4 first-level indicators have 15 secondary indexes.
Based on the AHP ,it hinder the implementation of BIM high-end talent training the weight of each factor

College education of BIM high-end talent countermeasures

Satisfy the demands of high-end talent fostering BIM technology
At present, the domestic BIM database development work is not perfect, and the existence of such problems as IT forces are relatively weak in the process of BIM high-end talent cultivation in colleges and universities .In order to solve this problem, the country can focus on cultivating talents

on BIM standards (put BIM standard research talent) and BIM tools (make BIM software tools development and research of talent).Government established the BIM software and tools, for example, research and development team, and with BIM technology developed countries (the United States, Singapore, etc.) on BIM technology exchange meeting, cultivating a understand information professional knowledge of sexual talents.Software development companies and research institutions can be committed to the development of BIM related software, can provide operating software for the society.

Solve the problem of talents fostering BIM funding

According to this article ,evaluation of high-end talent fostering BIM bottleneck analysis is derived from the funds of the issues hampering the more facing colleges and universities.To solve this problem, from the state, universities and enterprises can take measures three aspects.The government should appropriately increase the fiscal expenditure of high-end talent fostering BIM.It regularly organize BIM technology expert lectures and guidance for colleges and universities, also it can create BIM communication society, which provide a platform for fostering BIM high-end talents.University management personnel shall adjust the BIM high-end talent training of education funds to purchase BIM software to provide teachers and students to learn hardware facilities.Teachers and students are encouraged to attend BIM technical training.Construction companies and BIM training institutions can make the corresponding contribution.The construction enterprise investment for colleges and universities, for example, cooperation to develop high-end talent plus;Training institutions and universities alliance, to lower the cost of both teachers and students study BIM software, etc.

Improve the operating environment of BIM high-end talent cultivation

In the process of BIM high-end talent cultivation in colleges and universities ,it faced with relevant experts, less teaching platform not perfect, and low software developer support.To solve these problems should be from the state, colleges and universities, and software developers.Countries introduced corresponding policy, perfecting the BIM database, and establish a system of BIM education system, as well as the development of China's construction industry to promote application of BIM technology is obtained and concrete goal, to various colleges and universities put forward operable, which helps for research;Colleges and universities can provide operating BIM software platform (e.g., colleges and universities established BIM training center), cooperating with BIM training institutions to establish a good interaction system.Software developers BIM software develope more adapt to China's development, the cultivation of the colleges and universities support policy, which will prepare for the implementation of BIM software development work.

Promote the fostering BIM high-end talent policies

Government can encourage eligible university priority to implement of BIM high-end talent training scheme.Found the problem from the university of training scheme and timely solve, sorting, summed up a set of feasible reform education plan, which is introduced in the universities.University management should not just be satisfied with their current mode of education.They should organize relevant personnel of colleges and universities hold seminars dealing with BIM technology revolution education mode reform policy.Recruiters (mainly refers to the enterprises related to construction) should realize that there exits storm by the BIM transition from 2 d to multidimensional , and the storm will bring change to the future development of the enterprise direction.For construction enterprises in the recruitment, it consciously choose BIM high-end talent for encouraging universities to develop high-end talent plus, and paying attention to the acceptance of BIM talent.

Conclusions

Currently, what BIM will cause a new round of revolution in the construction industry after CAD has no doubt because government had to write BIM clear into the development of construction industry "Twelfth five-year" plan and it will be phased in and go deep into the construction of various fields.BIM is expected to become the theme of China's construction industry information in the next decade.It analyzes the bottleneck of BIM high-end talent cultivation, and find out the key

factor affecting college education of BIM high-end talent.From the perspective of countries, colleges and building enterprise it put forward countermeasures, receiving in the process of promoting talents fostering BIM always adhere to the "national guide, industry forward".Providing effective BIM high-end talent cultivation in colleges and universities of the platform, We look forward to the smooth implementation of colleges and universities to develop high-end talent plus plan just around the corner.

Keywords EMS; Purchase cost; Cost control

Abstract The rapid development of electronic technology has produced numerous demands, which have generated a new-born industry--EMS. In EMS corporations, purchase cost is a large proportion of total costs, so purchase cost control is one of the key competitiveness for EMS. Analytic Hierarchy Process (AHP) help EMS solve the problem of purchase cost control.

Introduction: The Analysis of Purchase Cost of EMS Corporations

EMS offer a service chain to OEM (Original Equipment Manufacturing). Chinese EMS industry is rapidly developing. iSuppli estimated that 75 percent of industry increases were made by Chinese EMS industry. But the average rate of net profits in EMS industry is only 2 to 5 percent. Purchase cost of EMS includes material costs, ordering costs, maintenance costs and shortage costs.[1]

Definition of Purchase Costs Control of EMS Corporations and their Limitations.

1. The definition of purchase costs control of EMS corporations.

1st parity purchasing. 2nd : centralized purchasing. 3rd : the third-party logistics . 4th : avoid import risks by localized procurement.

2. Limitations on purchase costs control of EMS corporations.

1st : ineffective purchase cost control: in the BOM of EMS, more than 80 percent of materials are appointed by OEM. 2nd : External market is unpredictable. 3rd orders uncertainties. EMS have to buy already-made products. 4th : some suppliers show incongruous when negotiating.

3. Using The Analytic Hierarchy Process (AHP) to Control Purchase Costs of EMS.

AHP[2] separates problems into factors then arrays hierarchies by comparing importance.

(1) The Establishment of hierarchical analysis model

① 1st "the best purchase costs control of EMS ". 2nd principal hierarchy: purchase costs projects controlled by customers. 3rd : the subprincipal hierarchy made by every factor.

② Take factor of principal hierarchy having downward affiliation as the first factor to make a judgment matrix.

Then fill in the judgment matrix by importance comparison as Table 1:

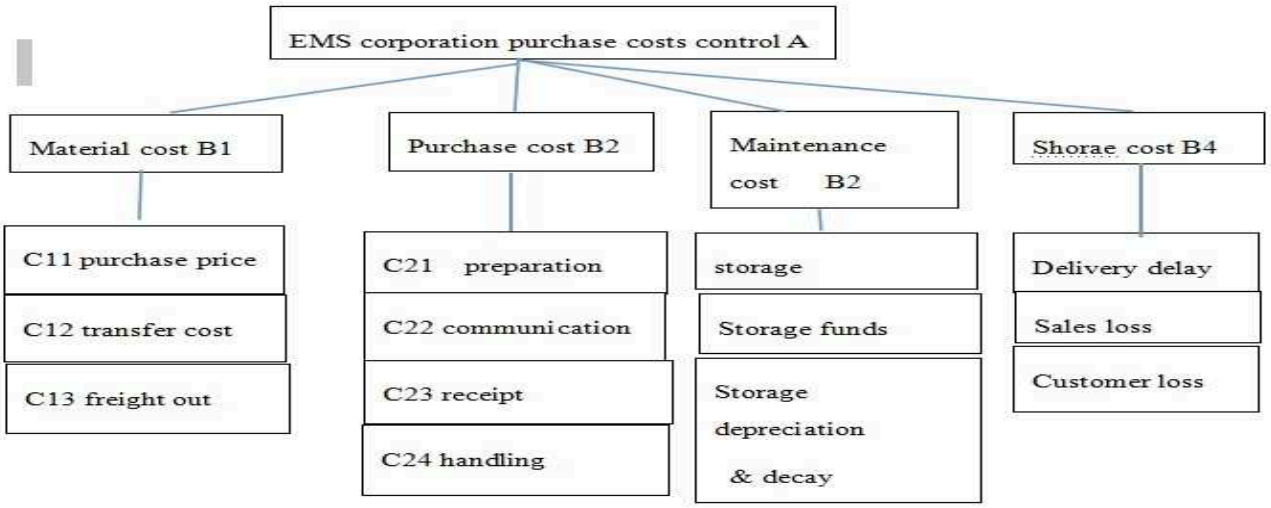

Fig 1. EMS Purchase Cost AHP chart

Table 1: Scale exponents to Evaluate Matrix Factor B_{ij}

Scale exponents	Meanings
1	The two factor weigh same after comparison
3,5,7,9	Factor i weighs more than factor j after comparison
2,4,6,8	The mid-value of exponents above
Reciprocal	Judgment of factor j and factor i is $B_{ij}=1/B_{ji}$

a. Invite S employees of EMS corporations and experts in related fields to participate.

b. Assign experts weights λ_k : high-grade experts weight 1.2, others weight 1, $\sum_{k=1}^{s}\lambda_k=1$.

c. Send the hierarchical analysis model, the blank judgment matrix and the table 2 to experts.

$$\overline{b_{ij}}=\sum_{k=1}^{s}\lambda_k b_{ijk} \tag{1}$$

$$\sigma_{ij}=\sqrt{\frac{1}{s-1}\sum_{s-1}^{s}(b_{ijk}-\overline{b_{ij}})^2} \tag{2}$$

b_{ijk} : given by K experts judging the factor in the i row and the j column of matrix.

a. Feedback the result and rejudge factor whose $\delta>\varepsilon$ =1, then establish the second cycle.

e. Factors whose standard deviation $\delta<\varepsilon$ =1, can be used as the values, Such as Table 3:

Table 2: $A \leftarrow \{B_1, B_2, B_3, B_4\}$

A	B_1	B_2	B_3	B_4
B_1	1	7	5	8
B_2	1/7	1	1/3	1/2
B_3	1/5	3	1	3
B_4	1/8	2	1/3	1

③ Compute the eigenvectors by "root method":

$$A=\begin{bmatrix} B_{11} & B_{12} & B_{13} & B_{14} \\ B_{21} & B_{22} & B_{23} & B_{24} \\ B_{31} & B_{32} & B_{33} & B_{34} \\ B_{41} & B_{42} & B_{43} & B_{44} \end{bmatrix} = \begin{bmatrix} 1 & 7 & 5 & 8 \\ 1/7 & 1 & 1/3 & 1/2 \\ 1/5 & 3 & 1 & 3 \\ 1/8 & 2 & 1/3 & 1 \end{bmatrix}$$

a. Compute the product M_i of factors in each row of judgment matrix A;

b. Compute the fourth power $\overline{W_i}$ of M_i;

c. Normalize $\overline{W} = (\overline{W_1}, \overline{W_2}, \overline{W_3}, \overline{W_4})$ and get the result:（0.6620, 0.0636, 0.1875, 0.0869).

④ Consistency check:

a. compute the eigenvalue of maximum $\lambda_{\max}$;

$\lambda_{\max} = \sum_{i-4}^{4} \frac{(PW)_i}{n\, W_i} = \frac{1}{n} \sum_{i-4}^{4} \frac{(PW)_i}{W_i}$, $(PW)_i$ is the i factor of PW, $i=4$.

$$PW=\begin{bmatrix} (PW)_1 \\ (PW)_2 \\ (PW)_3 \\ (PW)_4 \end{bmatrix} = \begin{bmatrix} B_{11} & B_{12} & B_{13} & B_{14} \\ B_{21} & B_{22} & B_{23} & B_{24} \\ B_{31} & B_{32} & B_{33} & B_{34} \\ B_{41} & B_{42} & B_{43} & B_{44} \end{bmatrix} \begin{bmatrix} W_1 \\ W_2 \\ W_3 \\ W_4 \end{bmatrix}$$

Plug the given values into it, we can get that $\lambda_{\max} = 4.4353.$

b. compute CI (Consistency Index);

$$CI = \frac{\lambda_{\max} - n}{n - 1}$$

c. Find corresponding RI (Random Index), shown in Table 4-8:

Tab. 3-8, Random Index

n	1	2	3	4	5	6	7	8	9	10	11
RI	0	0	0.58	0.90	1.12	1.24	1.32	1.41	1.45	1.49	1.51

Get RI from Table 3-8. A is a matrix with fourth order, and its RI =0.90.

d. Compute CR (Consistency Ratio);

$$CR = \frac{\text{CI}}{\text{RI}}$$

$A = \{B_1, B_2, B_3, B_4\}$=（0.6620, 0.0636, 0.1875, 0.0869）

CR =0.0501 <0.1, this judgment matrix is consistent. So, $A = \{B_1, B_2, B_3, B_4\}$=（0.6620, 0.0636, 0.1875, 0.0869)

e. Compute the weights set; Take *B1* as an example:

$B_1 = \{C_{11}, C_{12}, C_{13}\} = (0.7334 \ , \ 0.1990 \ , \ 0.0676 \ )$

Consistency check: $\lambda_{\max} = 3.0940$, $CI = 0.0470$, $CR = 0.0810$ <0.1

⑤ Results analysis:

EMS should pay more attention to cost with higher weight.

Table 3-9 Weight and rank of each item in total purchasing costs(Take A and B1 as examples)

Code	Item	Weight	Subcode	subitem	weight	Average Weight	rank
A	Purchase cost	1.000					
B1	Material cost	0.6620	C11	Purchase price	0.7334	0.4855	1
			C12	Transfer cost	0.1990	0.1317	3
			C13	Freight out	0.0676	0.0448	5

How to control purchase cost of EMS corporations

① Purchase price control

a. Use Target Cost Management, since what EMS presuming for is PPV (Purchase Price Variance).

b. Use Target Cost Management to control purchase price: compare standard one and real one.

c. If the price is predicted to be stable, long-tern cooperation can avoid purchase risk.

② Storage cost control

a. Establish effective information channels , combining bar code, POS systems and EDI.

b. Build rapid response system to set up a common cooperative goal.

The Application of The Multimedia Technology in College Physical Teaching Reform

Shi Jian-hua

School of Science, Communication University of China Beijing 100024,China
shijh@cuc.edu.cn

Keywords: Multimedia Technology; College Physics Reform；Teaching Effect

Abstract. This paper aims to effective combination between college physics and multimedia to optimize the teaching procedure of physics as a serious basic course in college. Through combining multimedia technology with the teachers' subjective initiative, perfecting multimedia course system based on the network, multimedia simulation laboratory organic coupling with real experimenting, we discusses how the actual teaching use of multimedia technology，explore the application of the rules and characteristics of multimedia technology. we are able to develop the advantages of multimedia and explore its potential so that we make it better service in physics teaching and enhance teaching effect .

Introduction

Physics is a natural science based on experiments. The knowledge, understanding and master of physics concept by students relies on the perception of physical phenomena. The content for teaching of university physics covers mechanical, thermal, electromagnetics, optics and modern physics with less relationship between them, and similar with that for high school physics curriculum, reducing students' interest. However, for traditional teaching of college physics, only certain physics experiments can be present to the students in the classroom, and the students can not access to dynamic and intuitive perceptual knowledge and clear physical pictures. Most students think it difficult to learn university physics. Although multi-media teaching method has been applied, it is still insufficient. The usage and method needs to be improved, and the means need further improvement and exploration.

Effective application of multimedia technology in university physics teaching can change the form of information, integrating graph, text, sound and image on PC, improving the expressive force of the teaching content, so that the students can actively participate in multi-media activities via multi senses, mastering the knowledge actively instead of passive acceptance. At the same time, it also provides a powerful tool for teaching and research, as well as reliable and technical support for smooth and efficient teaching. In addition to improvement of knowledge, application of multimedia can make the single straight teaching content intuitive, so as to inspire the enthusiasm of students, improving learning efficiency. Integrating graph, text, sound and images, the multimedia courseware can not only reproduce or simulate various physical experiments and phenomena, but also simulate the physical process, presenting physical laws more intuitively, so as to increase expression of the teaching content, mobilize students to participate in multi-media activities via multi senses, improve classroom atmosphere, attract the attention of students to better stimulate learning interest, while contribute to clarifying the physical ideas, processes and methods. Application of multimedia technology can provide students with vivid, clear, realistic emotional material in the classroom, so that students can perceive complete, clear and image physical phenomena which is difficult to observe or achieve, feel many scene which is impossible in traditional teaching in classroom, building physical model with initiative. Moreover, the students

can understand physical concepts, laws and theorems more easily; at the same time, the teaching is easy and the efficiency is increased.

By effective application of multimedia courseware in university physics teaching, the writing and drawing amount of teachers on the blackboard will be reduced greatly. The teachers can spend more time for lectures, delivery more quality information in the classroom with same teaching hours compared with traditional means. Therefore, it is necessary to use multimedia courseware effectively in the university physics teaching, and significant to improve college physics teaching effectiveness and level.

Effective Usage of Multimedia Technology in University Physics Teaching

Effective Combination of Multimedia Technology and Teacher's Initiative. Most concepts and laws in common university physics textbooks are derived via abstract theories and complex mathematical formulas. For the students, it is very difficult to master and understand the physical concepts and laws via complex mathematical formulas in a short period. As a classroom teaching aid, the advantage of multimedia courseware in the physical classroom is dynamic simulation, which can simulate visual experiments via unique analog animation, creating good physical scenarios to stimulate students' interest. So the students can achieve distinct impression, grasp and understand physical concepts and laws quickly.

In practice, the multimedia courseware for university physics must be fine and simple, demonstrating critical contents. The multimedia should mainly solve important and difficult points for classroom teaching, explain and deal with physical theories, processes and phenomena which are difficult to clear via traditional methods and media.

Application of multimedia courseware in university physics to make up traditional teaching not only saves the time, meeting teaching requirements, but makes abstract physical content more visual and intuitive via combination of video and audio means. In addition to shorter teaching time and higher teaching density, the teaching efficiency and quality is greatly improved, so as to accommodate and promote combination of university students with their ability.

There are two sides to everything, including multimedia teaching as a new form of teaching means. The teachers must not weaken their dominance in the classroom just for using of multimedia courseware. To avoid using of multimedia lesson as another blackboard and teaching the students just via the video, the teachers should focus on guiding students to analyze physical phenomena and principles, inspire and coach students to think, deepening understanding of physical concepts, processes, laws and theorems, teaching students to analyze and solve problems.

Improving of Web-based Multimedia Courses. University physics covers mechanical, thermal and electromagnetic contents etc. Generally due to less class, the students’ questions can not be resolved in time, and difficult to review, weakening the enthusiasm of students to a certain extent. Qualified teachers can provide college physics multimedia course system, including complete teaching files, clear requirements and rich materials, covering course, submission and correction of homework, analysis of samples, simulation of exams and real-time Q&A etc.

Online University Physics Multimedia Paper Evaluation System is a new model of teaching management. This system provides the students with a set of university physics simulation exams for the students to simulate test on PCs and prepare for formal exams. Through the system, the students can test mastering of university physics by themselves in order to consolidate learning results. University physics examination mainly tests mastering of basic physics knowledge by the student, covering multiple choice, true-false, fill-in-blank, short answer, calculation and proofs. After the student submits the test, the scoring system gives the score immediately, so as to stimulate student's motivation for learning. At the same time, the system must be able to collect and store student's number, name, profession, class, scores and other information, to provide raw data for analysis of the paper and mutual assessment between different courses, so as to provide the basis for teaching management, feedback of teaching information and improvement of the quality.

Combination of University Physics Multimedia Simulation Lab with Real Experiment. Physics experiment is the basis of physics, an integral part of physical education, promoting teaching of physical theories. Real experimental demonstration is an irreplaceable part of university physics teaching, playing a complementary role. Demonstration experiment is set to compensate the teaching content in class, which is mainly operated by teachers. A well-designed experimental demonstration will show the basic physical quantities in a simple form, helpful for students to establish a physical image of abstract concepts, contributing to understanding and mastering of the concept and laws, breaking through difficulties, broadening view of students, stimulating imagination, increasing interest of learning, and bringing up of students' ability.

The simulation laboratory is an innovative model of physics experiment teaching, integrating lab equipment, teaching content, teachers' guidance and thinking/operations of learners organically via PCs, forming a lab system to simulate virtual experimental environment. The system provides a powerful tool for physics experiment teaching, while overcoming the long-term class/time limitation of experimental teaching, extending the content concerning time and space, effectively improving the quality of preview, review and the experiment, comprehensively improving the actual ability, helpful for training of innovation and exploring spirit, so that the students can obtain systematical experimental theoretical techniques and complete skills.

Almost all physical process, phenomena and experiments can be reproduced vividly via multimedia means. Thus some teachers tend to use multimedia courseware instead of the real demonstration experiments in the class, completely dependent on the multimedia courseware. This teaching idea and method shall be corrected. The teachers must carry out real demonstration experiment in the classroom for students instead of multimedia tools as possible to demonstrate physical processes and phenomena. On one hand, this will train students to observe and analyze the real physical processes and phenomena, guide students to master the physical nature, understand and grasp the real nature; on the other hand, it will train the students to respect scientific idea and spirit of exploring for truth.

Conclusion

High-quality university physics multimedia courseware is the best means to provide a variety of audio-visual images, which can show a lot of physical processes and phenomena vividly which is difficult by common means. Especially, it combines the advantages of multimedia courseware for

university physics and that of traditional teaching of physics, greatly improving teaching results of college physics. Therefore, it is very important to strengthen and improve research of university physical multimedia technology, focusing and strengthening combination of advantages of multimedia technology and traditional teaching, so as to improve the quality of university physics teaching.

Prediction of Cigarette Sales Amount and Average Price based on Lunar Calendar

Yang Xiao

School of Management Science and Engineering, Shandong University of Finance and Economics, Erhuan East Road 7366, Jinan, China

Email: yangxiao@sdufe.edu.cn

Keywords: Cigarette Sales Prediction; ARIMA; Lunar Calendar

Abstract. Prediction of cigarette sales amount and average price is important for anomaly detection of orders, customers and cigarette brands. Besides this, prediction can be support of storing and production arrangement. By analyzing large amount historical sales records, a cigarette sales amount and average price foresting model is built to predict the weekly sales based on ARIMA model which using lunar time as the calendar. Result on the five years sales data from a Chinese city indicate that sales prediction based on ARIMA using lunar time can be an effective way to improve forecasting accuracy.

Introduction

In Chinese, tobacco sales are monopolized by the tobacco companies, so the prediction of sales volume and average price of all kinds of cigarette, and sales of each tobacco band are very important for the tobacco companies to analyze user preferences in each region. Prediction of cigarette sales can be used to guide the cigarette company to stock and develop sales policies according to smokers' preferences [1, 2].

There are a large number of orders and customer information during several years' accumulation in cigarette companies, which contains a wealth of information. We can use these data to predict the sales amount and average price using machine learning method.

Sales of cigarettes showed obvious seasonal fluctuations [3]. For instance, people will present gifts to each other in traditional holidays, and cigarette is one of welcomed gifts as a means of people interaction. Thus, cigarette sales increase much more influenced by the impact of holidays. Sales amount from years 2008 to 2012 of a municipal cigarette corporation is shown as an example in Fig.1. Meanwhile, the average price of the cigarettes is also showed obvious seasonal fluctuations, where Fig. 2 is shown as an example.

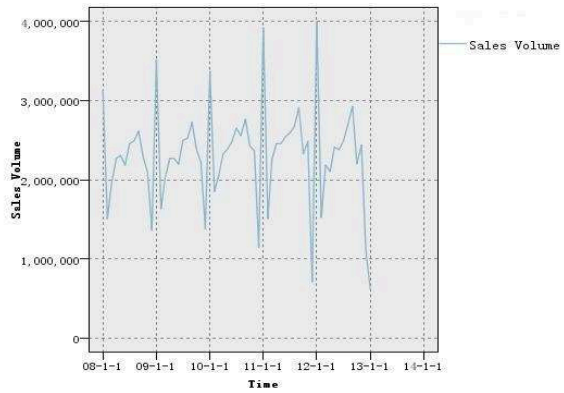

Fig. 1 Sales amount of a city in years from 2008 to 2012.

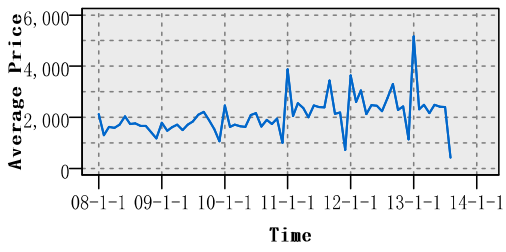

Fig. 2 Average price of a city in years from 2008 to 2012.

As can be seen from the cigarette sales amount and average price as Fig. 1 and Fig. 2, we can find cigarette sales meet the obvious characteristics of time series, and the time series of cigarette monthly sales showing seasonal fluctuations trend, therefore it often consistent with the typical characteristics

of double trend, and the predicted value tends to have a high correlation with the history of cigarette sales. For such complex nonlinear system, the classic stochastic models such as moving average and regression are unable to get satisfactory results, so we choose the ARIMA (Auto Regression Integrated Moving Average) model, which is a parametric stochastic model to detect the cigarette sales anomaly.

ARIMA Model

The ARMA model, which is a very suitable for predicting a stationary time series, is widely used in forecasting random phenomena of physical science, economics, weather etc.

Optimized from the ARMA model by an extra operation of difference on a non-stationary time series, ARIMA model [4] is used to forecast non-stationary time series. Non-seasonal ARIMA processes are defined by:

$$\theta_p(B)(1-B)^d y_t = w_q(B)a_t \tag{1}$$

where B is the backward shift operator, and for a non-stationary time series y_t, $(1-B)^d y_t$ could come to a stationary series by using the difference operator $1-B$. B satisfies $By_t=y_{t-1}$ and $B^k y_t=y_{t-k}$. Additionally, p, d and q are integers. The equations

$$w_q(B) = 1 - w_1 B - w_2 B^2 - w_3 B^3 - \cdots - w_q B^q \tag{2}$$

$$\theta_p(B) = 1 - \theta_1 B - \theta_2 B^2 - \theta_3 B^3 - \cdots - \theta_p B^p \tag{3}$$

are polynomials in B of degrees q and p. The integer d is the number of regular differences, p is the order of $\theta_p(B)$, q is the order of $w_q(B)$, and a_t is a current interference with mean = 0 and variance σ^2. Typically, we consider a_t as the estimated residual at time t. Meanwhile, a_t is also an independent and identically distributed normal random variable. The roots of $w_q(y) = 0$ and $\theta_p(y) = 0$ should all lie outside the unit circle.

The ARIMA model can get a reliable predictive result to short-term forecasting which have stable and seasonal characteristics, and can achieve the desired confidence interval. In addition, ARIMA model has strong flexibility, and it can express the various properties of time series of the data. So, ARIMA model is a widely applied time series model has been analyzed extensively by researchers and used widely by forecasting practitioners due to its attractive theoretical properties and empirical evidence.

Prediction on ARIMA Using Lunar Calendar

In some traditional lunar festivals, especially Autumn Festival and Spring Festival, which are the most important traditional festivals to Chinese, people have custom to send each other gifts [5]. High-grade cigarettes and wines are one of the important gift-giving items. Therefore, the sales of cigarettes will surge in these traditional festivals. This trend can be reflected in consumer sales fluctuations in Fig.1 and Fig. 2. Therefore, we are modeling ARIMA on lunar time to forecast sales when encounter the Chinese traditional festival, while forecasting based on solar time in other time.

Since the ordering is arranged by week, that is to say, customers have only one chance to order cigarette in a week, we predict the weekly sales amount and average price. Using the weekly sales data between years 2008 to the first half of 2013, we forecast the sales amount and average price of the next 4 weeks. The prediction is done on solar and lunar calendar separately. After deleting the null record, prediction based on ARIMA model is carried on in Clementine which is widely used data mining software. Prediction on the solar calendar and lunar calendar are carried through respectively to test the effectiveness of time-series analysis model established on lunar time. After differencing, the Clementine choose automatically ARIMA(1,0,2) for average price and ARIMA(2,0,7) for sales amount on solar time, and choose ARIMA (0,1,2) for average price and ARIMA(1,0,7) for sales amount on lunar time. The prediction results are shown in Fig. 3 to Fig. 6. From the figures, we can see intuitively that the ARIMA model can fit the data well.

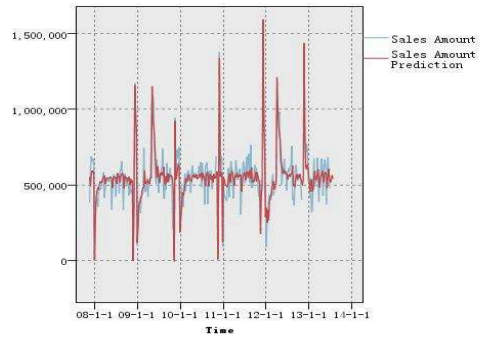

Fig. 3 Prediction of Average Price on lunar Calendar

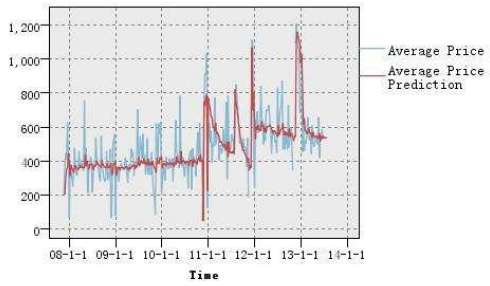

Fig. 4 Prediction of Sales Amount on lunar Calendar

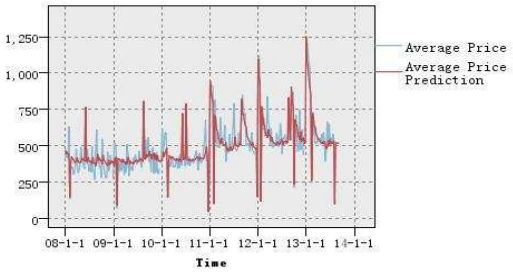

Fig. 5 Prediction of Average Price on Solar Calendar

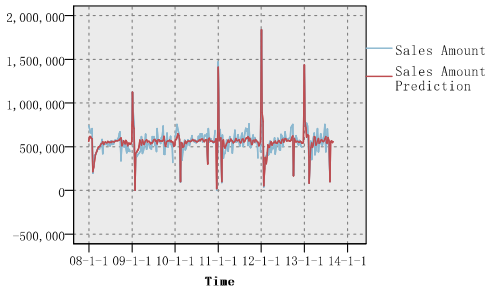

Fig.6 Prediction of Sales Amount on Solar Calendar

To compare the predictive effect of weekly sales volume and average price on solar calendar and lunar calendar, the metrics R2, RMSE, MAPE and MAE are given in Table 1 and Table 2.

Table 1. Weekly prediction accuracy of sales volume on solar and lunar calendar.

	on solar calendar	on lunar calendar
R2	0.8663	0.9307
RMSE	137055.1	176713.4
MAPE	4.945791	5.846084
MAE	96897.58	123969.8

Table 2. Weekly prediction accuracy of average price on solar and lunar calendar.

	on solar calendar	on lunar calendar
R2	0.7760	0.9613
RMSE	420409.7	269789.5
MAPE	8.9541	5.1877
MAE	276129.8	176978.4

Assume a data set has values y_i, and each of which has a predicted value $\hat{y}_i$, the four metrics are defined as follows:

$$R^2 = 1 - \frac{\sum_i (y_i - \hat{y}_i)^2}{\sum_i (y_i - \bar{y})^2}, \quad \text{where } \bar{y} = \frac{1}{n}\sum_{i=1}^{n} y_i \tag{4}$$

$$MAE = \frac{1}{n}\sum_{i=1}^{n} |\hat{y}_i - y_i| \tag{5}$$

$$RMSE = \sqrt{\frac{1}{n}\sum_{i=1}^{n} (\hat{y}_i - y_i)^2} \tag{6}$$

$$MAE = \frac{1}{n}\sum_{i=1}^{n} \left| \frac{\hat{y}_i - y_i}{y_i} \right| \tag{7}$$

The MAPE of four models are all under 10, which illustrate the predictive accuracy on both lunar and solar calendar is relatively high. From the tables, we can see that the predictive accuracy based on lunar is better than on solar in general. Especially R2, which is a metric to measure the fitting degree of model, model on lunar is much better than the one on solar. And the RMSE, MAE and MAPE of sales volume on lunar calendar are lower than the solar calendar, which show the superiority of the

model. But the RMSE, MAE and MAPE of sales volume on lunar calendar are higher than the solar calendar. Through analyzing the data, we found that the lunar time is cannot be used directly in the model. For example, the month April and May in year 2012 is both convert to April, because April in lunar year 2012 is an intercalary month in the lunar calendar. Then the sales volume in April of year 2012 is summed by April and May in solar calendar, so it is extremely high. But the average price is not affected by the intercalary month in the lunar calendar, so all of the metrics is better than the solar time. Based on the above discussion, the prediction on lunar time is used only when encounter lunar festival, and prediction on solar calendar is used for other data.

Conclusion

ARIMA model consider trend variation, periodic variation and random disturbance comprehensively, and the model parameters can be quantified to remove people's subjective judgment to a certain extent, so it is widely used in prediction.

This paper used five years data to predict the sales amount and average price of the cigarette, this work can help officers to specify cigarette market.

The conversion from solar time to lunar time is not much accurate, manual correction should be done to improve the predictive accuracy. The sales amount and average price can be affected by other factors, such as policy. The future work should include these factors.

The study of SWOT analysis and countermeasures on developing tourism resources in Xinxiang City

Xiuxia LI

School of Art and Design，Xinxiang University,Henan,China,453000

14878670@qq.com

Keywords: SWOT analysis ; tourism resources; Xinxiang City

Abstract: In the course of developing regional tourism resources, there are certain strength, weakness, opportunity and treat, which can be exchanged each other. To analyze SWOT factors scientifically and suit measures to local conditions serve to change disadvantages into advantages and challenges into opportunities. The paper analyses SWOT in Xinxiang city and realizes that Xinxiang should establish itself both in resources and market. Xinxiang should develop from all directions and depth.

0.Introduction

Andrews SWOT analysis is a strategic analysis framework proposed by the American scholars in the 1970s which is a method to the development direction for the research object with the comprehensive consideration of SW (internal strengths and weaknesses) and OT (external opportunity and threat), With the deepening of tourism and related disciplines, the tourism development mode based on the SWOT which is more and more mature, has become an important tourism development process analysis method.

1. Advantage in developing Xinxiang tourism resource

Richness in natural, excellent cultural resources.

Xinxiang is rich in natural tourism resources, famous TaiHang mountains is located in the south of Xinxiang[1].Due to the Taihang mountains in the geography of the second and third stage joint, natural formed unique cliffs, cliffs, waterfalls, temperature Spring, is the first choice for people of the north travel for an outing. Xinxiang's tourism as the pillar of the henan tourism area, within its borders Thousands of taihang mountain scenic spot has a beautiful town, baligou's water scene, guanshan's lofty mountain, huilong's jun, male of baoquan, as well as the king of qi village and paomaling amorous feelings. Xinxiang, relying on the unique natural scenery has become a henan tourism Card, every year attracts millions of tourists at home and abroad to visit and sightseeing. In addition, xinxiang is rich in water resource, is located in Two main river of the Yellow River, the haihe river. Xinxiang Yellow River communist-held existing a large number of lakes, swamps and wetlands, a national forest Park, wetland nature reserves and other precious natural resources.In addition, xinxiang has a long history and profound culture Background, Xinxiang is the activity center from xia-shang-zhou dynasties, the shang dynasty were reincarnated. In the long history of xinxiang Its unique historical and cultural background for human left behind the precious wealth and rich historical relics，familiar King zhou period's story coring of bigan. Chow time's makino war, Spring and Autumn Period's relieve the state of Zhao by besieging the state of Wei[2].

location advantages

Xinxiang is in the center of the south taihang tourist area which is located in the central plains earth, and belongs to the national economy geographical center area.And zhengzhou in henan province and adjacent flap with radiation of the north. in a very important position, for example, Through the economic and cultural hub of north and south China city beijing-guangzhou route, across the two stone corridor route(Taiyuan to shandong stone mortar)，xinhe route etc(Xinxiang to shandong's heze),intersect north-south, east-west.The urban construction, the road ahead, national key construction of the ashen(Nei Menggu the town of arong to shenzhen)，Xinling highway(xinxiang to shanxi lingchuan) in xinxiang, for site, powerful traffic advantages, laid the foundation for the development of xinxiang.Not only such, xinxiang adjacent to puyang, anyang, hebi, zhengzhou and other people Populated cities, nearly three hundred million people, especially the implementation of

the intercity bus, more to shorten the time of the people's inter-city exchanges.Xinxiang distance key cities of Beijing, xi'an, baoding, xuzhou, jinan, wuhan distance less than half a day, xinzheng international Airport less than 100 kilometers, which can reach Hong Kong, Macao region and Europe, and in several countries.Xinxiang developed transport hub for the discovery of the rapid development of the tourism industry have laid a solid foundation.

government policy provide

The development of tourism can not do without the strong support of government agencies, henan provincial party committee, the provincial capital successively put forward the related countermeasure, issued a series of documents to promote the discovery of the rapid development of the tourism industry[3].In October 2005, the tourism industry development in henan province Conference held in zhengzhou, meeting influence the rapid development of tourism in henan province are emphatically resolved a series of key issues, in the history of tourism in our province is of epoch-making significance.In addition, the provincial government will also be supported by the ministry of tourism is divided into seven advantage industry, the establishment of reward incentive system, strengthen the tourism industry of manpower, material resources and financial input.Then, take the lead in tourism resources in our province census, provincial leadership into each scenic spot research, make a different in different scenic spot below and reply,such as the south taihang mountain tourism development planning and the advantages of funiu tourism development planning, etc.

Henan has well aware of the characteristics of the scenic setting，On the river Amorous feelings of south area idiosyncrasies, draw the grand blueprint one body two wings "development of tourism in our province, so as a national demonstration provinces. Xinxiang actively responded to an appeal by the provincial party committee and government also actively introduced "xinxiang municipal party committee and the municipal people's government of xinxiang on accelerating the development of tourism opinion "and so on to promote rapid development of the whole city's touristry file, the file clear Put forward: Government fiscal spending 5 million yuan a year traveling special funds, actively the construction of national key projects, thus promote local government initiative to develop tourism booming tourism industry in henan province and xinxiang government entities at all levels for tourism Attaches great importance to, and provides the xinxiang tourism development premise.

tourism advantages

xinxiang As China excellent tourist city is rich in natural and human tourism resources, tourism development of water flat is higher, have relatively complete tourist service facilities and many famous tourist products, annual number of tourists and tourism revenue also are increasing year by year, has the good foundation for the development of tourism. According to statistics, xinxiang received from 2012 domestic visitor numbers up to 19.9818 million passengers, up 21.6%.Domestic tourism income of 12.61 billion yuan, year-on-year growth of 24.9%, higher than the entire province average growth rate of 3 and 5% respectively, domestic tourists from the province's seventh promotion to sixth place[4]. Received more than one hundred people travel more than 1000 teams, is reception for the whole year one hundred to 2011 on the amount of team nearly twice as much. The outbound tourism continues to increase, the reception of immigration reach 50000 in 2012.Smooth travel security situation is good, the city's tourism measured control within 0.5 ‰.In recent years, with the continuous development of the tourism market, the government is in deepening on the importance of tourism industry, Xinxiang tourism with scientific development view as guidelines, insist on planning first, market guide, industry regulatory thinking, vigorously improve the continuous improvement of the tourist service facilities to improve the quality and service management, make the tourism discovery, long-term development. At the same time, this series measures also xinxiang tourism and tourism resources for the future development laid a solid foundation.

2 Building Xinxiang tourism resource development mode

Tourism resources development pattern is refers to the development of main body of tourism resources in the tourism industry into the sum of the general process and basic way, it is the tourism

resources development activities in time on the process and way of implement the most general highly generalization and summarization of the characteristics and laws. Tourism resources development pattern, which is based on development practice, summarizes the experiences of the development process, and used to guide the development of tourism resources. Mode with its characteristics and laws of different, at the same time the benefit of society, environment, economy also different. For the tourism resource development as well. Therefore, for the discovery of tourism resources development pattern, also should start from the basic characteristics and laws, to find a suitable characteristic ways of xinxiang tourism resources development activities, realize the sustainable development of the most suitable and optimized path.(shown in Fig,1)

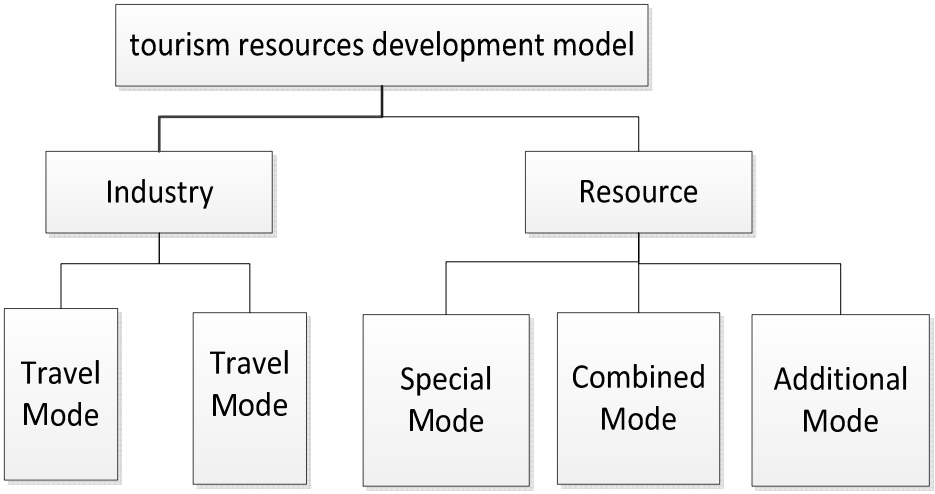

Fig 1.Resource development mode

Resource development mode

So-called type special tourism resource development refers to a kind of tourism product development target, will travel resources to develop it into a unique tourist attractions, tourists travel purpose is simple and the attractions[5]. At present, before relying on the natural resources of xinxiang developed rock climbing, mountain climbing, skiing, rafting, cross-country, etc. Human resources development include the new temple fair once a year and springs of the exchange of medicinal materials, etc.

The combination of tourism resources development pattern

Combination of tourism resources development requirement in the process of resources development, the development main body, not just the resources is the development together with the other tourism resources together. In this form for development, mainly for those relatively rich resources and has a beautiful natural scenery and rich culture and history of the region, in the development process , the resources occupies a certain weight. The purpose of going somewhere for tourists sightseeing is not just to participate in the body Education activities, and to explore its beautiful natural landscape, appreciate the local strong cultural atmosphere. For scenic spots , development work should focus on integration of resources, planning "ecological tourism" line, to do with The tourism industry chains interaction and coordinated development.

Marxist Philosophy in Object-Oriented Practical Education

Meng Zhang

Editorial Department of journal, Xinxiang University, Henan, China, 453003
837457026@qq.com

Keyword：Marxist；object-oriented；Xinxiang University

ABSTRACT: Marxist, the renowned mathematician and philosopher, advocated combining theory and practice in education, emphasizing methods by which to grasp and use knowledge. Education has both regular and irregular characteristics and these are reflected in how individuals develop and grow naturally. Individuals should be taught based on their abilities and circumstances, and these vary by individual. An example is given in this article, to demonstrate the contemporary significance of the Marxist process in education. This example refers to applying Marxist's process philosophy to object-oriented practical education in communication major at Xinxiang University.

INTRODUCTION

Marxist, a distinguished educator in Germany, believed that above all things education should integrate theory and practice. Education should produce a student who not only has knowledge but applies excellence to the way they carry out practical tasks [1]. Theory and practice should be incorporated into education and supplement one another. Knowledge is relevant only when it is applied in practice.

Marxist, encouraged people to be motivated about practice. He believed that when a student acquired theory without practice, then, such knowledge was a waste. Knowledge is important only when it is applied practically and only, when, it is understood by people. Knowledge's worth totally depends on who masters it and what he/she uses it for. The truly valuable education is one that teaches students to understand thoroughly some universal principles, which then, can be applied to dealing with various, specific situations. Practice originates from, and is closely tied to, daily life; and knowledge ought to serve daily life.

The quality that education should impart is a deep recognition that power, theology and organization lie in knowledge and, as well, there is a special kind of knowledge having to do with who knows it well. He further believed that another aspect of education is to pass on wisdom. Wisdom involves an approach to learning and knowledge. Wisdom is essentially the ultimate freedom that one can acquire. Education should be targeted to make individuals wise and the only path to wisdom is freedom of knowledge, where freedom means an individual can learn, understand knowledge and, then, apply it in practice [2].

The education process

In Marxist's theory, teaching is a process that follows a number of rules manifested by certain steps in the process of education. Intelligence develops in steps, each of which contains a few cycles or iterations that intertwine, while the whole process is a small eddy of individual growth as part of a bigger cycle or iteration. The steps reflect certain, universal rules that are rational and reasonable. Learners develop their knowledge gradually and iteratively. The teaching process should be advanced iteratively and the steps should not be rigid.

Marxist strongly criticized the common viewpoint prevailing at his time, that a student's progress was a steady, unvarying development irrespective of the type of student. He thought education was a challenge that could not be solved by a simple formula. Marxist, mathematician and philosopher, also thought it was impossible that there were any abstract rules that suited all subjects, students of all kinds or that could be used to teach the right knowledge to each student. Each student at each stage in education is unique.

Process in developing person's intelligence

Marxist divided the education process into three stages: the romantic stage, the precision stage and the application stage.

The romantic stage is when students begin to comprehend, but knowledge is not systematic; the precision stage is the period where students gain more knowledge to increase and supplement their earlier learning, and where they acquire facts in an organized way and expand the general learning of the romantic stage. The application stage is the ultimate goal: to comprehensively apply knowledge after learning the concepts and the pertinent skills .

The growth of knowledge is the result of the ordered, harmonious and iterative development through the three stages[3]. A learner, in the process of study, should be assigned tasks matching the stage he/she is in, or his/her development will be affected. If viewed by age, the three stages correspond to infants and young children, teenagers and university students, with each stage requiring the right courses and in small steps.

The right content should be taught based on the stage, the level of knowledge and the intellectual capacity of each student. No student can tackle the three stages concurrently. Whitehead emphasised that teaching content requiring diverse comprehension should be put into different, subordinate cycles. Through this a harmonious pattern takes shape in the student's mind. Meanwhile, teaching quality should improve as education adapts to the stage that a student has reached. He believed that ignoring the pacing and factors that influence education was the main cause of poor and inefficient education.

The education process

Marxist criticized the view that treats the brain as a kind of lifeless tool and the most dangerous view that persists in education theory. He thought the human brain has never been passive and negative but is constantly active, receiving and responding to external stimulation in a fine and acute way. As with tools sharpened before use, the human brain keeps developing. An infallible law in education, also a hard law to follow, is that teachers should motivate their students, regardless of the response by students to the teaching [4]. This requires teachers to show great patience and to make a huge effort.

The challenge here is to recognize intelligence and to motivate the drive to achieve, which cannot be awakened just by words.

Any teacher with experience knows that education is a demanding process requiring much patience in delivering detail in an iterative manner day after day. Therefore, to Marxist, when teachers analyze the central mission of education, they would find that achieving the mission depends on making an optimum adjustment to a number of variables.

The reason is that educators are dealing with live human brains. For students, the thirst for knowledge, their judgements and their mastery of complexity, must be developed to enable them to apply theoretical knowledge to particular situations. These abilities cannot be delivered through one fixed approach, e.g. as implied by the current examination system. So, teachers must implement the educational process in the right way for individual students and at the right time.

Object-Oriented education

Marxist believed that students' study in different stages is an iterative process; each stage contains cycles which contain smaller cycles. Therefore study is progressive. This educational paradigm is also applicable to college students who major in engineering and, especially, in practical education, which develops application-based engineering talents. In this article, an example is drawn from Xinxiang University's communication major in developing application-based engineering skills. This exemplifies the development and improvement in students' ability, through practicing Marxist's process.

A student majoring in communication engineering needs to study for four years: common basic courses in the first year, specialized basic courses in second year, specialized courses in third year and specialty-based field work in fourth year.

Using Marxist's process concept, the entire four-year study is deemed a large cycle, with each academic year as a step of the cycle, as shown in Figure 1.

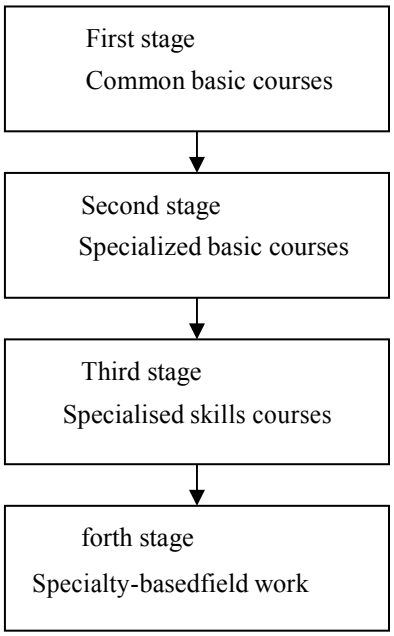

Figure 1: Steps in the object-oriented course.

Marxist's process philosophy on education advocated combining theory and practice. It also placed weight on learning from practice. He upheld that education should be implemented progressively in stages and that teaching should follow the law on an individual's personal development.

He believed that knowledge should be taught with passion to motivate students to learn. This practice has demonstrated that Marxist's process philosophy on education meets the need for reforming Chinese higher education.

Keyword: basketball; zone defense; basketball tactics

Abstract: In basketball, you want to win the game not only have sharp offense, but more impregnable fortress-like defense. With the development of basketball, individual technical ability in the game is growing, shooting is more and more accurate, offensive means are more and more rich, together with the positive moves of the players in the game, facing the complex and changing field conditions, if just blindly individual defense, it is difficult to obtain significant results. Zone defense, with variability and flexibility, can effectively limit the player with strong individual ability and come through the defense to win the game, and therefore zone defense tactics attract more teams' attention.

1 Introduction

At first, zone defense tactics are relatively rigid to follow certain routines by rote. Basketball is a flexible team sport, due to a fixed routine for regional defense, the defense will become counterproductive, which did not play a role in limiting the opponent, and while it will expose the defensive weaknesses, leading to lack confidence in the players and finally only negative defense. Due to the promotion of professional basketball, a lot of athletes are training from childhood, whose individual technical ability in the game is growing, shooting is more and more accurate, offensive means are more and more rich, together with the positive moves of the players in the game, facing the complex and changing field conditions, if just blindly individual defense, it is difficult to obtain significant results. In basketball, the offensive and defensive influence each other, and if you have a good offensive, the other on defense is bound to consume a lot of energy, and will be fatigue in the attack leading to mistakes; Of course, if the defense is targeted, the attack is difficult, and a lot of energy will be spent, physical power problems in the defense will be up against other causes of untimely filling in, et al. Currently the world's top teams are using forms of zone defense, the defense diversification, both pertinence and flexibility, expanding the area of zone defense. Since there is no formation of the importance of defense, at the 2006 World Championships, although the players come from the NBA's top players, shown in figure 1, the U.S national team passes the puck by the star personal capacity, the Spain team, with a strong team defense and flexible zone defense tactics, defeated the powerful American star team, and won the championship, which gives a vivid lesson to the world basketball.

Figure 1 Tracy McGrady and Kobe Bryant fight

2 Zone defense tactical awareness and training

To play good defense tactics in the game, it is unavoidable to train before the game. We need to have a specific concept what is zone defense, grasping well zone defense tactics' development and change. Mainly from the following three aspects to learn and train zone defense:

First, some people may have the wrong understanding, they think the defense is rigid, too passive, and unable to withstand the changes in strategy. If there is no defense, that left only man-to-man defense, facing the attackers of strong personal ability, the defense would be empty. Because of having not deep understanding of zone defense tactics, you may consider zone defense is negative defense, without a collective zone defense tactics, of course, it cannot be sufficiently powerful. In the zone defense we need to timely adjust the emphasis of defense based on the opponent's offensive system, focus on defense for strong scoring ability, and impose defensive effectiveness.

Second, it is necessary to understand the development of the zone defense, initially it is marking tactics, and later with a number of fixed zone defense tactics, and finally developing into a comprehensive zone defense tactics, by reading the game, you can make targeted zone defense tactics. So the zone defense began to have "living thought", transforming the defense based on the realistic.

Third, training is needed, if having not tactical training before the game, it cannot play a decent fit in the game. It is necessary to conduct research on the history of video and tactical analysis during training. For important tactical moves, defense tactics are needed to keep combat training. You need to seriously understand own team's defensive weaknesses, and to make up for deficiencies through collective defense, while to adjust the athletes' good physical condition, in a lot of games, because the main players physical exertion premature is too early, the team are turned defeat into victory by the opponent lightly.

3 Zone defense tactical requirements

Zone defense requires players to be arranged when the other team throw in the ball or losing own goals. If losing the ball in front court due to being stolen or the error, all the players should get back in time, and try to avoid being hit fast-break by the opponents and dribble the ball to prevent the other's progress. In trench warfare, you should have special care of the opponents' offensive strengths' players, and take appropriate defense based on the offensive side. The team should

maintain a tacit understanding between the players, closer in time to the defensive side of the ball handler, and cut off passing lanes, causing the ball handler who barely shots or turnovers. In the direction of the mobile defense, the players need timely help the passing person, and avoid the opponent can directly open shots after passing. Zone defense is the formation of much less proof through an active athlete running, if the other party has a good No. 1 players, the ability to pass the ball more prominent, which is likely to cause up against not timely, resulting in open shots , easy baskets. In order to compensate for the lack of zone defense, you must understand the opponent's strengths and weaknesses, such as the other players, whose shooting is not acute, properly allowed open shot, and a strong focus on the players who have strong ability to score. When sealing the passing lanes, you can intentionally or unintentionally let out to the opponent's more mistakes or favorite singles player routes, force them to pass, and defense the singles players by double team to reluctantly shot. In this case without worry, we should continue to use this defense tactic, as the other's individual player emotion is provoked, he will not pass the ball, zone defense will produce miraculous. If not scoring defense you can grab a basketball by the top people through zone defense tactics, the sideline players can fast break. In short zone defense should attack different tactics, and have different arm for different teams, not rigid and fixed pattern.

4 " 2-1-2 " zone defense

There are many ways in zone defense, such as 3-2 defense, 2-3 defense, " 2-1-2 " defense, because the length of this paper is limited, this paper mainly introduces the specific requirements and training of the " 2-1-2 " zone defense. There are main exercises such as judging the opponent's breaking route, to predict and intercept the route in advance during practice, grasping the movement of the opponent, effectively stealing, judging and destroying its passing lanes. It is that through cooperation and division of labor between the players, zone defense takes the use of collective force on the offensive conduct of the other side, and has the purpose of limiting and destruction. In "2-1-2" zone defense, our players' positions are shown as blues in Figure 2, the reds are the offensive team players.

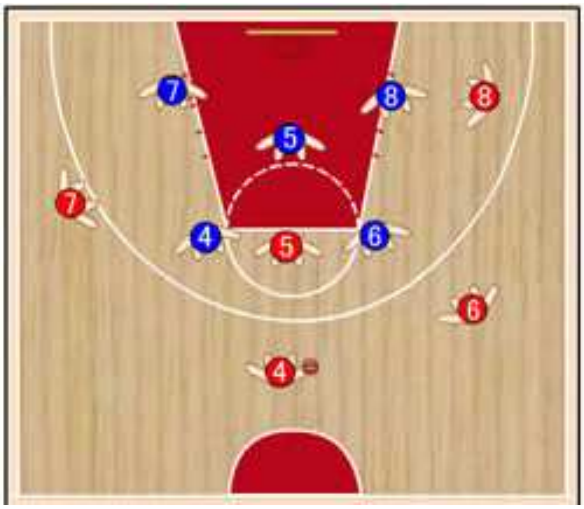

Figure 2 " 2-1-2 " zone defense

Here for the "2-1-2" defense gives the corresponding defensive manner:

First, defensive player would like to strengthen the defense of favorable position for attacking, if the 4th red is the ball handler, the 4th, 6th should be close to the handler, and force him to pass the ball to the 7th or 6th red, after the Red 7or 6 catches the ball, the Blue 4 and 7 defense the Red 7, the Blue 6 defenses the Red 6, which will make it difficult to form an effective attack. Second,

predicting the passing lanes and breaking it in advance, if the ball handler is the Red 8, he has only two choices, offensive or passing the ball to Red 6, if he passes the ball to Red 6, Blue 6 should promptly cut off the route, and Blue 5 helps Blue 6, if Red 8 chooses the offensive, Blue 5, Blue 6 and Blue 8 can be close to him, in the case of one offensive and three defense, he is difficult to have a successful attack. Third, facing tactical defense to three points, you should timely defense him and ensure less foul. If Red 7 has strong shooting 3 points ability, Blue 4 and Blue 7 should pay attention to timely running with the ball, go up in time to limit him once the ball is into the hands of Red 7. Zone defense requires a tacit understanding and timely filling in between players, the immature zone defense can easily be cracked. During the competition, the individual's defensive ability is important, but without team work, it is difficult to win the game, which requires players to practice more and form tacit understanding in order to have an iron-clad defense.

[a]lbsswh@163.com, [b]zzyuan@bjtu.edu.cn

Keyword: urban transport; land-use; urban construction area; road area; microscopic model

Abstract. Urban land-use plays a critical role in the traffic congestion performance and serves as the key ingredient in establishment of cities. To explore the interactive relationship between urban transport and land-use is of great significance for solving the problem of urban traffic and sustainable development. On the basis of microscopic model for the interactive relationship between urban transport and land-use, our paper analyses the interaction between urban construction area and road area, whose dynamic variation is proposed in the simulation. A programming model is presented to assess to the transportation and construction depending the parametric values. Our paper proves that changing the behaviors of travel and improving degree of mixed land-use appropriately can increase the urban construction area, eventually reaching the coordinated development between urban transport and land-use.

Introduction

Along with the rapid advance of urbanization, the traffic problem has become the main bottleneck restricting the development of modern city [1]. Traffic imbalance between supply and demand is the direct cause of the urban traffic problems, the solution of which includes two aspects: expanding the traffic capacity, coordinating the relationship between urban transport and land-use to reduce and optimize the distribution of traffic demand, ultimately alleviate the contradictions [2]. At home and abroad this aspect was confirmed from theory to empirical research. In quantitative analysis, we have done a lot of research on the micro level, but the research between urban construction area and road area which are the most basic microscopic indexes of urban construction area and the road area has not been researched. Based on it, we make quantitative study on this relationship and present some suggestions and measures to solve the urban traffic problems.

Interactive Relationship between Urban Construction Area and Road Area

The relationship between urban construction area and road area represents essentially the relationship between land-use and urban transport [3], which is shown in Fig. 1.

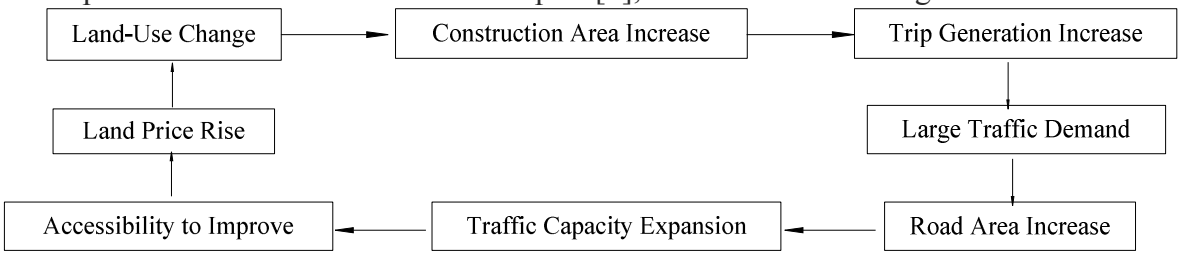

Fig. 1 Feedback loop between urban construction area and road area

In the chain of the Fig.1, land development will increase the total construction area of the region, cause a lot of trip generation. With the increasing of traffic demand, lots of traffic facilities will be needed, such as increasing road area, and traffic capacity will be larger, traffic accessibility will be improved, the land price will rise, which will attract further land development. Ultimately, a new cycle will begin. It will reach a stable equilibrium state of "complementary symbiosis".

The interactive model of urban construction area and road area

Model assumptions

(1) Urban road area is limited;

(2) Urban construction area and road construction area obey the logistic diffusion when they have independent developments without the influence each other [2].

Model parameters

$p(t)$: urban road area function; $p(0)=p_0$: urban road area at the initial time.

$q(t)$: urban construction area function; $q(0)=q_0$: urban construction area at initial time.

$\alpha(p)$:the growth rate of road area, assume the function is $\alpha(p)=\varepsilon(1-p/p_m)$, ε is the inherent growth rate of construction area when road area increases, p_m is the largest road area.

$\beta(p)$:the growth rate of construction area, assume the function is $\beta(p)=\xi(1-p/p_m)$, ξ is the inherent growth rate of road area when construction area increases.

Model construction

$p(t+\Delta t)-p(t)=\alpha(p)p(t)\Delta t$; $q(t+\Delta t)-q(t)=\beta(p)q(t)\Delta t$

The equations above are simplified as [4]:

$$p'(t)=\varepsilon(1-p/p_m)p(t) \quad (1)$$

$$q'(t)=\xi(1-p/p_m)q(t) \quad (2)$$

Model analysis

(1) Solve the equation: $p'(t)=\varepsilon(1-p/p_m)p(t)$

Put $p(0)=p_0$ into the equation(1)，the result of the differential equation is

$$p(t)=p_m/1+(p_m/p_0-1)e^{-\varepsilon t} \quad (3)$$

The function image of $p(t)$ is shown in Fig 2:

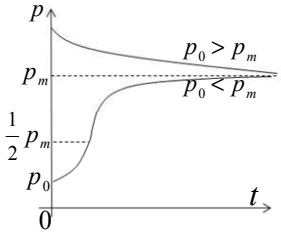

Fig.2 The change of road area

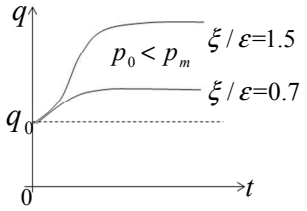

Fig.3 The change of urban construction area

We can get the following conclusion from the Fig.2:

①The original road area has a direct impact on the trend of road area. When $p_0 > p_m$, the road area is reducing over time, this is apparently not practical significance, when $p_0 < p_m$, the road area is growing over time, eventually reaching the largest value.

②The growth of road area presents obvious phases. When $p_0 < p_m$, the change of road area has three phases: rapid growth before 1/2 p_m, growth rate gradually accelerated; then stable growth, growth rate is slower; finally the slow growth.

(2) Solve the equation: $q'(t)=\xi(1-p/p_m)q(t)$

Put $p(t)$ into the equation(2)，the result is: $q(t)=C(1+be^{-\varepsilon t})^{-\xi/\varepsilon}$ (4)

Because of $b=p_m/p_0-1$; $q(0)=C(1+b)^{-\xi/\varepsilon}$; $C=q_0(1+b)^{\xi/\varepsilon}$,we can get the following equation: $q(t)=q_0(1+b)^{\xi/\varepsilon}(1+be^{-\varepsilon t})^{-\xi/\varepsilon}$; $\lim_{t\to\infty} q(t)=q_0(1+b)^{\xi/\varepsilon}=q_0(p_m/p_0)^{\xi/\varepsilon}$

Assume that ξ/ε=1.5 and ξ/ε=0.7 , put them into equation (4), the function image of $q(t)$is shown in Fig.3, we can get the following conclusion from the Fig.3:

①The initial road area directly affects construction area trend. When $p_0 < p_m$, construction area eventually reaches the limits of construction area: $q_0(p_m/p_0)^{\xi/\varepsilon}$; the growth of construction area presents obvious phases. When $p_0 < p_m$, the construction area increases fast and then it increases slower, and its growth rule is similar to $p(t)$; the long-term stable state urban construction area $q_0(p_m/p_0)^{\xi/\varepsilon}$ is ultimately determined by road area, so the growth of road area can not only restricts construction area but also promotes the growth of urban construction area.

②ξ/ε:the relationship between the driving force of road area to urban construction area and the driving force of urban construction area to road area directly affect the ultimate urban construction area $q_0(p_m/p_0)^{\xi/\varepsilon}$, and it's an exponential function.

(3) Function about road area and urban construction area:

Put $p(t)$ into $q(t)$,we can get the function of $q(t)=q_0 p_0^{-\xi/\varepsilon} p^{\xi/\varepsilon}$ in Fig.4:

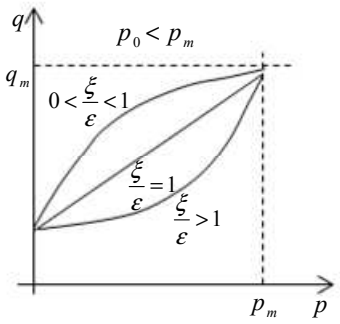

Fig.4 Graph about urban construction area and road area

The Fig.4 showed that the growth rate of urban construction area is affected by ξ/ε: $\xi/\varepsilon>1$, urban construction area will grow more and more rapidly; $\xi/\varepsilon=1$, it will grows linearly; $0<\xi/\varepsilon<1$,urban construction area will grow more slowly.

Relevant suggestions

The maximum of urban construction area $q_0(p_m/p_0)^{\xi/\varepsilon}$ is closely related to p_m, ξ and ε. p_m represents the traffic capacity of region, which is related to the transportation infrastructure capacity, the level of transportation management and travel behavior; ξ represents the guidance of road area, which is related to travel behavior, ξ guided by TOD mode[5,6] is bigger than that guided by car mode; ε represents the guidance of construction area, related to the choice of travel mode, degree of mixed land-use[7], etc. If too much emphasis on the unity of it, it will increase the urban traffic load. So the strategy of improving urban construction area is to increase p_m, ξ and reduce ε.

Summary

To improve p_m is to increase road area, essentially to increase traffic capacity, so the transportation infrastructure, especially road traffic space is firstly adopted measure.

But in the big city, city space is reducing, so the effective way of increasing construction area is to change the traffic development mode, it means paying more attention to the public traffic planning, which will increase ξ.

Improving mixing degree of land-use in the urban planning, considering the balance of different land-use, avoiding the increase of the travel distance from the source and reducing the imbalance of travel in time and space can reduce ε.

In conclusion, there exists the interactive trend between urban construction area and road area, and they basically show the periodic growth, so we should adopt different traffic planning and traffic policy aiming at different growth stages.

Keywords Public hospitals; Social Responsibility; Accounting Information Disclosure; Countermeasures

Abstract. Implement the social responsibility accounting for public hospitals is a new field to study the social responsibility accounting, aims to facilitate the implementation of the social function of public hospitals and adhere to the essence of "public welfare". At present, the social responsibility accounting information disclosure is still in suspended phase, many theories and methods are still being explored under study, and study more concentrate in the corporate section. This paper proposes countermeasures and suggestions on how to improve public hospitals social responsibility accounting information disclosure, on the basis of analyzing public hospitals' the social responsibility accounting information disclosure in the face of difficulties.

Introduction

Social responsibility accounting is a branch of accounting, which is the subject for social impact of the organization of economic activity to be measured and reported, applying the accounting basic principle and method. Taking the public hospital's social responsibility information into financial accounting and appraisal system has become irresistible trend of social responsibility accounting development in the future, while the use of social responsibility accounting will greatly promote disclosures of social responsibility, which has important strategic significance for the sustainable and healthy development of public hospitals. Because of the social responsibility accounting information disclosure research is still in its infancy, yet no systematic theory of social responsibility accounting information disclosure system. Hence, the difficulties to implement social responsibility accounting information disclosure and corresponding countermeasures of public hospitals are discussed.

1. Overview of public hospital social responsibility accounting information disclosure.

Public hospitals social responsibility accounting information disclosure refers to the process that public hospitals use unique methods and techniques, revealing information included the status of public hospitals social responsibility and the impact of the public hospital's financial condition and operating results caused by social responsibility. The specific content is through the measurement and reporting to the case of performing the social responsibility for public hospital, providing useful public hospitals information to all the interests of individuals or groups related to public hospitals operating activities, so that they can make the right and effective decisions[1].

2. The difficulties of public hospitals social responsibility accounting information disclosure.

2.1 From the government's perspective.

Due to social responsibility accounting moderate development in China, so the Chinese government has not yet formally introduced standardized, improved "social responsibility accounting standards", "social responsibility auditing standards" and can truly standardize and guide the effective regulations and industry standards for social responsibility to fulfill, resulting in no laws for public hospitals to depend on. In addition, the social responsibility accounting regulation has not yet commenced, hospitals, neither internal audit nor annual CPA independent audit stated by new "hospital accounting system" involve in this social responsibility accounting. Thus, resulting in deficiency of legal basis public hospitals fulfill to their social responsibility or

large subjective arbitrariness, causing great obstacles to the specific implementation of social responsibility accounting information disclosure for public hospitals.

2.2 From the perspective of social responsibility accounting.

First, compared to the Western developed countries the research on the social responsibility accounting started late, with a low degree of attention, social responsibility accounting theory is still very weak, also did not set up specialized research institutions, research in hospitals and other public administrative institutions is almost blank. Furthermore, because of the particularity and complexity of social responsibility accounting measurement, making it different from traditional accounting in the aspects of accounting principles, accounting hypothesis, accounting methods and reporting patterns, and how to deal with these differences, how to form complete theoretical system of complete community responsibility Accounting, will also be facing difficult for social responsibility accounting implementation.

2.3 From the view of public hospitals.

On the one hand, public hospitals, social responsibility consciousness, lack of awareness of the report. Currently one-sided introducing business management experience and applying entrepreneurial mode of operation in the public hospitals, the one-sided emphasis on operational risk aversion and excessive pursuit of economic interests, directly or indirectly harm the public interest for the access to health care, played down the public health care institutions should have asocial responsibility to the public[2]. Our hospital industry as well as internal social responsibility management system is still in its infancy, in the preliminary practice and exploration process, without systematic and in-depth theoretical studies[3]. On the other hand, the cost of public hospitals social responsibility accounting is higher. Due to the complicated and extensive social responsibility accounting information content, it takes a large amount of manpower and resources to investigate; social responsibility accounting information disclosure still need the accounting personnel training, which will result in providing the high cost of social responsibility accounting information, affecting public Hospital enthusiasm.

3. Countermeasures of implementing public hospital social responsibility accounting information disclosure

3.1 should promote the implementation of government-led public hospital social responsibility accounting information disclosure framework.

(1) Improving law. The law is the most powerful means to protect the state, society and people's interests, closely linked between law and practice, and only according to the law, the law must, the state organs monitoring have ability to effectively supervise public hospitals to fulfill their social responsibility, to promote social responsibility accounting information disclosure move towards standardization. Therefore, to promote the development of social responsibility accounting information disclosure, the establishment and improvement of the legislative work related to social responsibility is an important aspect that does not allow to be ignored.

(2) Developing guidance. Social Responsibility Accounting Standards is the fundamental basis of social responsibility accounting, also an important measure to implement management for the social responsibility accounting. Academia should learn theoretical results and practical experience from Western accounting profession, combined with China's specific situation, referring to the basic procedures of accounting standards, study and establish social responsibility accounting standards and industry rules. Public hospitals formulate social responsibility accounting information disclosure, taking the special nature of association of public hospitals into account.

(3) Establishing an incentive mechanism. Currently global social responsibility accounting information disclosure is voluntary, public hospital social responsibility can adopt the way combining the mandatory disclosure and voluntary disclosure of accounting information disclosure. Generally, for reasons of confidentiality, poor public hospitals voluntary disclosure initiative of social responsibility, lack of social responsibility information disclosure, it reflects the lack of current information disclosure orientation and external incentives. We should establish incentive mechanism to encourage voluntary disclosure of environmental and social responsibility

information, system of rewards and penalties on social responsibility information disclosure behavior of public hospitals, rewards and punishment measures.

(4) Constructing a supervision mechanism. The composition of public hospital social responsibility accounting information disclosure supervision mechanism should be in two parts, one is the internal supervision, and the second is external supervision. Establishing and perfecting internal and external public hospital supervision mechanisms, place the behavior of public hospitals social responsibility information disclosure under internal and external monitoring, so that implement of social responsibility and social responsibility accounting information disclosure for the public hospital move towards standardization, rationalization. Supervision should be taken the external supervision as the principal thing, strengthening external supervision of social responsibility accounting information disclosure, social responsibility audit and taking social responsibility audit incorporated into the scope of public hospitals annual audit.

(5) To adopt the opened way on the implementation gradually. The process of establishing social responsibility accounting is not achieved overnight, should take a gradual approach, from simple to complex, from junior to senior, from the individual to complete[4]. This gradual opened way mainly includes three aspects: First, disclosure should be from less to more, from easy to difficult, gradually increase disclosure content along with the continuous improvement of social responsibility accounting theory and practice. Second, the disclosure model began to take a combination of qualitative and quantitative way, a gradual transition to a quantitative report mode, the evolution from primary mode to advanced mode. Third, the choice of disclosure subject should be re-opened the first pilot program. First, choose the economically developed areas or more robust accounting management of Large and medium-sized public hospitals as pilot, and then gradually extended to other public hospitals.

3.2 to strengthen research on social responsibility accounting information disclosure theory and practice.

Social Responsibility Accounting is an emerging branch of the accounting discipline, strengthen research on social responsibility accounting information disclosure theory and practice will help promote the development of social responsibility accounting and accounting reforms in the deepening. First, accelerate social responsibility accounting information disclosure theory research and perfect the social responsibility accounting information disclosure theory system. Accelerate the social responsibility accounting information disclosure theory research, including the purpose, content, pattern, recognition and measurement methods of social responsibility accounting information disclosure. In the theoretical research, we should pay attention to absorb and learn from related disciplines, pay attention to Western theories and experiences absorption and learn to do theory research of coexistence of traditional accounting; both can be completely complementary through coordination research[5]. Second, strengthen practical research. From the social responsibility accounting information disclosure practices perspective, China's social responsibility accounting information disclosure in practices are relatively backward. Practices research should be strengthened according to China's national conditions and combining with the foreign experience of accounting information disclosure, we explore to establish a sound social responsibility accounting information disclosure system, with a clear measurement, records, reports of social responsibility accounting information, guiding social responsibility accounting information disclosure practices of public hospitals.

3.3 to strengthen their sense of public hospitals, improve accounting personnel knowledge structure.

To develop social responsibility accounting information disclosure in public hospitals, first of all, public hospitals should have a correct understanding on its social responsibility. Secondly, whether public hospitals have social responsibility consciousness, the degree of strength of social responsibility consciousness is directly related to the social responsibility accounting information of public hospitals could be disclosed, whether or not the question of disclosure is complete. As a public hospital, not only individual leaders and management decision-making departments should have social responsibility consciousness, which is more dependent on the hospital staff to undertake

social responsibility well. Strengthen social responsibility consciousness of public hospitals constantly, proactively discourse social responsibility information, promote sustainable development of public hospitals.

Information on the situation of public hospitals to fulfill their social responsibilities ultimately needs to be disclosed by the accounting personnel. Disclosure of social responsibility accounting information far beyond the traditional accounting to accounting personnel requirements, so this requires subsequent accounting personnel education with a combination of knowledge about the social responsibility accounting, improve accounting personnel knowledge structure, improve the quality and level of accounting personnel and promote public hospital social responsibility accounting information disclosure .

Keywords: corporate social responsibility to employees,game,voluntarily.

Abstract. The rapid development of economy, changed the original enterprise development goals, from the pursuit of economic interests to bear social responsibility is a huge transformation, and the staff as the core enterprise. Employees are paying more and more attention. In this paper, the private voluntary provision of public goods game model analysis the performance of China' corporate social responsibility to employees voluntarily,and it arrives at the conclusion that China's large enterprises are willing to bear the social responsibility for the staff, and small enterprises just are hitchhike. Finally, combined with the actual situation in China, in our implementation of corporate social responsibility to employees and provide advice.

Introduction

With the development of economy , the enterprise 's role in society has changed . First , enterprises only pursue the maximization of enterprise profit , regardless of the enterprise's employees , consumers etc. . At present , put forward higher to request to the enterprise , to the enterprise stakeholders responsible for . According to the stakeholder theory , having a direct or indirect contact with the enterprises are the stakeholders of enterprises , the development of enterprises , and the staff is the enterprise's core and the most direct stakeholders of enterprises .The staffs of the enterprise value are more and more important .Also it is very important for the long-term development of enterprises .

With the employee status is rising in the world, according to the employee social responsibility of trade barriers also emerge as the times require, China is a large developing countries, international development, is is the development target of China's enterprises, so the enterprise social responsibility to employees is essential for Chinese enterprises. Therefore, based on the private supply of public goods game model, analysis of China's enterprise social responsibility voluntarily to employees to perform, and finally puts forward some implementation of enterprise social responsibility to employees and suggestions.

Game model analysis

The hypothesis of social enterprise in n, n=1…i, in the process of establishing the social security system, different enterprises are different social responsibility to its employee costs. Assuming that each enterprise expenditure is divided into two parts, one part of the input $p_G g_i$ for enterprise social responsibility for employees, p_G provides enterprise social responsibility for the staff of the unit value,g_i for the enterprise i to the total amount of investment of the employees, it is the equivalent of public goods expenditure.The total investment of the corporate social responsibility to employees is $G=\sum_{i=1}^{n} g_i$ .A part of the outlay for enterprise $p_x x_i$ is to other stakeholders to fulfill their social responsibilities including shareholders, creditors, consumers, it is equivalent to the enterprise private goods expenditures. When the enterprise social responsibility to its employee, also can get social recognition q_i, increase their utility, can be recognized with the society, acceptance of

hypothesis of enterprise i is $q_i = \gamma x_i$, and the enterprise to provide the relevant staff input. If the enterprise of the efficiency of the i is set to u_i, can according to the production function with $u_i = q x_i^{\alpha} G^{\beta}, \alpha + \beta > 1$, that is to promote the role of utility staff to fulfill the social responsibility for enterprises. The enterprise i 's income is limited, let enterprise income constraint for I_i, $I_i = x_i p_x + g_i p_G$.

Based on the above assumptions, the optimal Nash equilibrium solution can be obtained. The enterprise is the ultimate choice to (x_i, g_i) to maximize the objective function, according to the Lagrange theorem constructor: $L_i = u_i(x_i, G) + \lambda(I_i - p_x x_i - p_G g_i)$, λ is the Lagrange multipliers.

The first order conditions for the optimized: $\frac{\partial u_i}{\partial G} - \lambda p_G = 0$, $\frac{\partial u_i}{\partial x_i} - \lambda p_x = 0$ .So $\frac{\partial u_i / \partial G}{\partial u_i / \partial x_i} = \frac{p_G}{p_x}, i = 1,2,\cdots n$.

According to the equilibrium condition of consumer theory, firms' investment and enterprise to other stakeholders input is the same, if the enterprise can realize the input of staff of other enterprises, the n equilibrium conditions decided to provide enterprise voluntary employee social responsibility investment, Nash equilibrium : $g^* = (g_1^*, \cdots, g_i^*, \cdots, g_n^*)$, $G^* = \sum_{i=1}^{n} g_i^*$.

Based on the above assumptions , Pareto optimality can ask . Assume that the social welfare function is related to all enterprises utility in the society , so the social welfare function is: $W = \theta_1 u_1 + \cdots + \theta_i u_i + \cdots + \theta_n u_n, \theta \geq 0$. The budget constraint for the total: $\sum_{i=1}^{n} I_i = p_x \sum_{i=1}^{n} x_i + p_G G$.

The first order conditions of Pareto optimality is: $\sum_{i=1}^{n} \theta_i \frac{\partial u_i}{\partial G} - \lambda p_G = 0$, $\theta_i \frac{\partial u_i}{\partial G} - \lambda p_x = 0, i = 1,2\cdots, n$

λ is the Lagrange multipliers.

Use the n equation to eliminate θ_i, it gets the Pareto optimal equilibrium conditions: $\sum \frac{\partial u_i / \partial G}{\partial u_i / \partial x_i} = \frac{p_G}{p_x}$.

The equilibrium condition of firm's utility function into the optimal, obtained: $\frac{\beta x_i^{\alpha+1} G^{\beta-1}}{(\alpha+1) x_i^{\alpha} G^{\beta}} = \frac{p_G}{p_x}$.

The enterprise i budget constraints: $I_i = p_x x_i + p_G g_i^*$

The budget constraint on the equilibrium conditions, have been collated, reaction function: $g_i^* = \frac{\beta I_i}{p_G(1+\alpha+\beta)} - \frac{\alpha+1}{1+\alpha+\beta} \sum_{j \neq i} g_j, i = 1,2,\cdots n$

Through analyzing the reaction function can know that: Enterprises i are willing to believe that other enterprises to employee more inputs. Enterprises i will provide employee social responsibility cost less. At the same time also we can see that the income of the enterprise is the impact on enterprises to fulfill their social responsibility to employees in.

The following discussion enterprise income different influence on Nash equilibrium and Pareto optimality.

(1) When all the enterprise society income is the same time, they are in Nash equilibrium conditions for employees in the same: $g_i^* = \frac{\beta I}{p_G[(1+\alpha)n + \beta]}, i = 1,2\cdots n$

At this time, the total supply of Nash equilibrium for: $G^* = n g_i^* = \frac{n\beta I}{p_G[(1+\alpha)n + \beta]}$

(2) When all the enterprises have the same income under the assumption, the first-order conditions for the Pareto optimal: $n \frac{\beta x_i^{\alpha+1} G^{\beta-1}}{(\alpha+1) x_i^{\alpha} G^{\beta}} = \frac{p_G}{p_x}$

And bring to the enterprise budget constraints,get the Pareto optimal an enterprise's contribution is: $g_i^* = \frac{\beta I}{p_G(1+\alpha+\beta)}$

At this time, the total of enterprises of employee involvement in the society: $G^{**} = n g_i^{**} = \frac{n\beta I}{p_G(1+\alpha+\beta)}$

By comparison, can be calculated by the ratio of total supply of Nash equilibrium and Pareto optimality of the total supply of: $\frac{G^*}{G^{**}} = \frac{1+\alpha+\beta}{(1+\alpha)n+\beta} < 1$

The comparison results can be obtained , all the enterprise society is less than optimal Pareto optimal state under the optimal total cost of staff to perform social responsibility investment of the Nash equilibrium , two relevant quantities of all enterprises under the state and society in the gap , expanded on the number of enterprises increased.

To study the relationship between the corporate investment and income of social responsibility to employees through a number of assumptions in the social enterprise.

The hypothesis of social enterprise is only two.The two enterprise income is same $I_1 = I_2 = 1.5m$, can get the Nash equilibrium: $(g_1^*, g_2^*) = (\frac{1.5m\beta}{p_G[2(1+\alpha)+\beta]}, \frac{1.5m\beta}{p_G[2(1+\alpha)+\beta]})$.

The total supply of Nash equilibrium for: $G^* = g_1^* + g_2^* = \frac{3m\beta}{p_G[2(1+\alpha)+\beta]}$.

Suppose the two enterprise income is different,assuming $I_1 = 2m, I_2 = m$, $\alpha \geq \beta$ explains the economic effect of enterprise, personal consumption to business bigger, for the Nash equilibrium: $g_2^* = \frac{\beta^2 - (1+\alpha)\beta}{p_G[2(1+\alpha)\beta+\beta^2]} m < 0$. Less than 0 is no significance,so $g_2^* = 0$, $g_1^* = \frac{2\beta m}{p_G(1+\alpha+\beta)}$.

Through the equation can get that only the high income of enterprises will provide fulfill their social responsibility to employees, the low income one just hitchhikes . The hypothesis of Social enterprise in high and low income is more in line with the actual situation . The results of the study fully explained , our business to employee social responsibility is the large enterprises are willing to bear the social responsibility of the staff .But Small enterprises are unwilling to bear the situation .

Summary

The staff is the core part of enterprises , enterprises do a good job of employee social responsibility , to the enterprise not only directly bring tangible economic benefits , but also brings intangible social value . At this stage the enterprise social responsibility to employees performance is not very good ,it can be seen from the above analysis , our country at present is only some large enterprises to fulfill social responsibility for employees , and some small enterprises are not aware of the employees to fulfill their social responsibility . There are no clear legal rules and regulations , so that our government should be from the following two aspects promote social responsibility to employees in small and medium sized enterprises .

(1) Establish and perfect the corporate social responsibility to employees of laws and regulations

The Chinese government has promulgated the relevant employees' rights protection law, the government can integrate the current relates to corporate social responsibility to employees of the laws and regulations of carding to establish a set of rich Chinese characteristic and conform to the times requirements of the system ,it can require enterprises . With the appropriate rewards and punishments, and the government is perfect and related supervision departments. It helps enterprises to fulfill their social responsibilities to employees,create a good economic environment, in order to maintain social stability.

(2) The establishment of enterprise employee social responsibility evaluation system

To establish a reasonable social responsibility appraisal system , is conducive to China's enterprises to exchange information , clear enterprise in social responsibility to its employee hand position , can provide a direction for the development of enterprises , but also for the government to provide a basis of rewards and punishment of enterprises . Our country can draw lessons from the internationally recognized OHSAS18001 or SA8000 system to establish suitable for China's corporate social responsibility to employees in the evaluation system .The specific requirements according to different characteristics of the industry to set different standards of the industry. The related departments of the government should regularly publish the evaluation results , let the public to participate in supervision and management .

The research of the second class credit in the credit system

ShuangLiang Yao[1,a] and ShuangTong wang[1,b]

[1]Jiangsu University of Science and Technology, JiangSu 212003, China;

[a]705514958@qq.com,[b]260925671@qq.com

Keywords: B/S, The Second Class, Credit Reporting.

Abstract. In order to solve the problem of the second class credit reporting in manual states, we use the system flow diagrams and case diagrams to analysis the needs of users, and use ER diagrams to introduce the SQL database。This article designs the system of the second class credit reporting based on the campus network. The system uses C # as the development language, SQL Server database as a background and Microsoft Visual Studio 2010 as the development environment, with high security and stability.

INTRODUTION

In order to develop the analysis, expression, understandings and creative abilities of students, and to improve students' creativity, flexibility, adaptability and activity, apart from traditional teaching schedule, university open up a second class base on credit system that develops students' strong points and solve problems between generality and personality .A second class credit management takes measures of students sign up independently. Then youth league committee examine and verify firm working process, in which there are lots of categories of projects, inconformity of subprojects' credits and numerous data sizes from students' signature. As a result, it brings enormous workloads of declaration and examination. In the recent years, with the scale of school expanding, number of students increasing quickly, traditional ways of handwork will consume large amounts of manpower, material resources and time, which will be wrong in the condition of data size that is large and complex, and can't meet the demand of high effective work.

As the technology develops, in the terms of shortage of traditional handwork, we design Internet function in the basis of .Net platform, using c# as developing language on the stage and SQL Server as invoking of database. The design of management platform of a second class makes it no-papering, networking, high efficiency to save humanity, materiality, and finance. In the meantime, it can solve some defects of handmade declaration to improve work efficiency and guarantee the strictness, security, efficiency and flexibility so as to reduce the rate of mistakes. So, on the new condition, it lays a foundation for developing talented people who are needed by the society that improving a second class to bring it into play with website.

The Analysis of a Second Class Credit Management Process

The users of a second class credit declaration system can be divided: Youth League Committee managers, the head teachers, students. User function can make true by B/S. Students can sign up the projects of a second class in the way of choosing projects' categories by themselves. And they can browse the state of examination and the obtained credits and required credits. The head teacher should verify the projects which are declared by students in class.

After verification, the credits should be automatically included in the students learning scores.

Meanwhile, the head teacher can change auditing or reporting on students to edit, delete operation.

The teacher can also see and export this class second class credit reporting according to the needs of real-time view. Committee of management mainly are responsible for maintenance of function, the basic information about teachers and students and can add, edit, delete information, import data in bulk. At the same time, the head teacher can see and export every class credit declaration. The system flow chart is shown in fig 1.

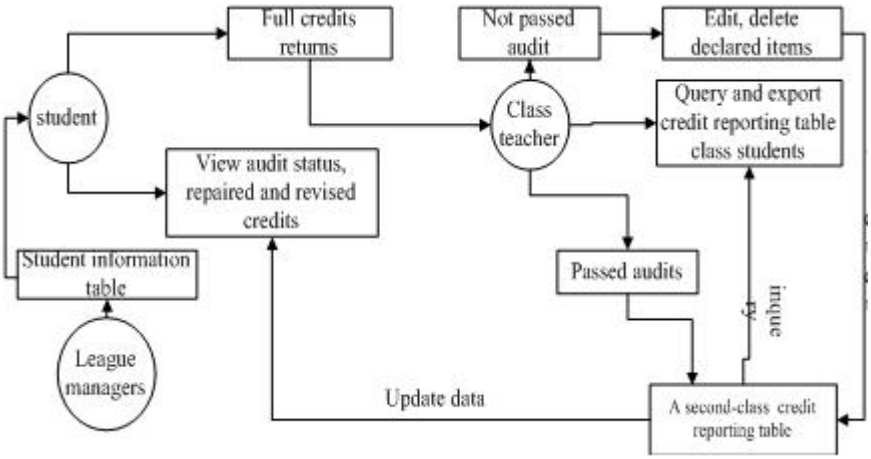

Fig. 1 The second class credit reporting system flow chart

The platform design of second class credit

The platform is secure and steady which uses c# as the development of language on the stage based on .Net environment. The system consists of three layers: the first one is former-end client browser. The client operating system involves a series of system such as Windows 2000 Professional , Windows XP, Windows 7 . The browser involves IE and other mainstream browser. It request to the web server with HTTP agreement. Any teacher, students can access the system through the campus network of PC; the second one is intermediate Web server. The server is made up of Windows 2000 Server, Internet Information Server (IIS), .net platform and the second class of credit reporting system; the third one is the backstage database. It uses the popular SQL Server as the back-end call. Also, it has data processing of high efficiency, good safety and can satisfy the demand of data access system. Web development environment has high scalability based on Microsoft Visual Studio 2010.

The Design of Module Function

Based on analysis of users' demand, the design of the system function structure as shown in Fig. 2:

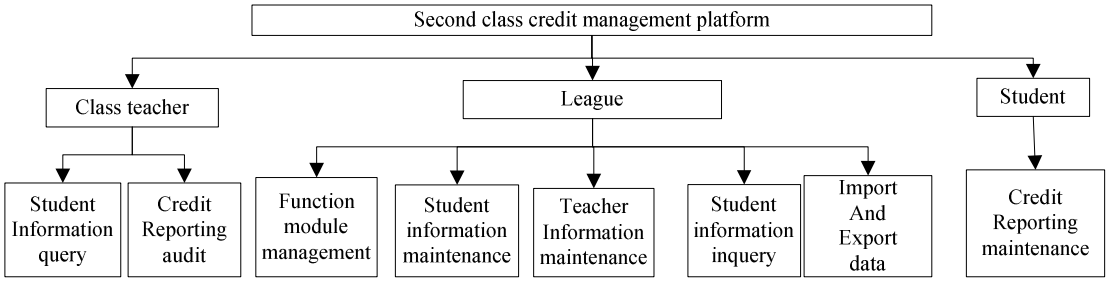

Fig. 2 Second class credit management platform functional structure diagram

Student Information Query: this function can be realized in the class teacher, administration interface. They can inquire the basic information of students according to students' name, class and other conditions.

The Credit Application: the function can be realized in the class interface. The head teacher can examine, check, modify, and delete students' declared projects. Meanwhile, Teacher can query and export related credit data according to student Id, audit condition.

Function Module Management: The administrator can modify the whole menu of system function, adding or deleting the function module.

Student Information Maintenance: this function can be realized in administration interface. The administrator can add, modify or delete student information.

Teacher information maintenance: this function can be realized in administration interface. The administrator can add, modify or delete the head teacher information.

Import and Export Data: this function can be realized in administration interface. The administrator can export data in bulk from Excel into corresponding Database or export data in bulk from Database into corresponding Excel according to needs.

The Credit Application Module: this function can be realized in student interface. In the module, students can add a credit project. When filling in declared projects, students select corresponding project categories and fraction in the form of drop-down box and fill in the application instructions. Sometimes, students can see the state of declared projects and modified or required credits in the module.

Database Design

This platform uses the relational database model. SQL completely correspond to the system requirement as the current mainstream relational database management system. It confirms that 8 database tables including administrator information table, restraint table, function module table, Student information table, the head teacher information table, credit application table, project categories table, project name table according to former analysis of system. It expresses the relationship among each database table involved with E-R chart. The E-R chart of system is shown .

The Realization of Main Technology and Effect of Application

The platform has three user group consisting of the administrator, teacher, student .It can make three kinds of users visit different dynamic menu modules through the control of role access.

First, establish three class user information tables in the SQL database and insert Group field into the table. At the same time, we should establish two tables: AdminUrl table, AdminGroup table. Then store the name of menu of function module, URL address in AdminUrl table. And the menu module corresponds to unique ID number. The menu module that user can get access to in AdminGroup table can be restricted. The menu module ID that each user group visit will be stored in the promise field. During the actual operation, in the landing entrance interface, users select corresponding user group by option group, which use the built-in Session object to store Group group (code omitted) and transfer it to the main interface. In the main user interface, use select statements promise field which satisfy the requirement of group=Session [“group”].To String in the AdminGroup table. The way of GetUrlByPromise () is to select menu module whose ID involves in Promise field in AdminUrl table. Finally，use the Append statement to add this menu module and display it in the main user interface on the left navigation bar.

Traditional manual ways in Jiangsu University of Science and technology take 8 people over half month to verify about 6 thousand people’s information. During the time, the error caused by huge workload brings longer duty cycle. Through the application of credit management platform of the second class, students can declare projects through a personal computer in the campus on their own and can view the state of verification from time to time. Compared to previous tedious manual application, the process in the declaration gets simplified. The class teacher and the youth league committee can manage credit application directly online. And they can export into the Excel according to requirements and improve the efficiency of work, decreasing the manual mistakes, as well as realize the paperless office.

Conclusion

The second class of credit management platform in the credit environment is established based on Jiangsu University of Science and Technology campus network system model. The platform is designed to meet the habit of user, and has friendly interface. It is easy to use and suitable for students and teachers and other groups of users. Based on ASP.NET technology, using the role

access control to realize online application and approval process, which has better security, efficiency and flexibility. By using the system, on one hand, it can improve the work efficiency of the second class and is consistent with trend of the network information of paperless office .On the other hand, it can compensate for single form of league work propaganda position, and strengthen the students' understanding of the second class to encourage students to learn in purpose.

Research on the Multidimensional Teaching Goal Setting and Implementation of Exhibition Lighting and Illumination design

Gong Qian
Hubei Institute of Fine Arts WhHan, 430205 China.
gongqian8@163.com

Keywords: lighting and illumination design; exhibition design; multidimensional teaching goal; model

Abstract. Hubei Institute of Fine Arts has been analyzing, sorting and studying the exhibition lighting and illumination design curriculum since the establishment of exhibition design major. Such curriculum includes various multidimensional objectives, such as exploring the design content of lighting effect of spatial form and exhibition props, investigation and estimation of natural and artificial light source as well as conception creation of scenario lighting effect, establishing model with strong lighting and lighting performance, etc. Based on the sorting and analysis of the curriculum system of "Exhibition Lighting and Illumination design" and exampled at excellent students' works, the multidimensional teaching goal and implementation of exhibition lighting and illumination design were interpreted systematically. This could provide basis for other associated colleges in launching exhibition lighting and illumination design curriculum.

Introduction

As the important procedure of exhibition design, exhibition lighting and illumination design refer to the creation of spatial visual image by integrating scientific and artistic lighting effect design with exhibition buildings and physical exhibition spaces. Such creation of spatial visual image not only provides comfortable visual presentation of exhibition goods and space and displays the real exhibition goods to improve their quality, but also includes the implication and guidance of visual psychology.

After taught theories of exhibition lighting and illumination design, students have to deeply analyze and sort the spatial lighting and illumination design requirements according to different exhibition space types, functional partitioning of spaces and scale demands, calculate and set natural light and artificial light, select the comprehensive lighting approach, conduct software simulation as well as final lighting effect design control in considering of the properties of exhibition goods and scale demand of exhibition props, create conceptive scenario lighting effect according to design style and visual presentation mode, and finally establish a model entity with stronger lighting effect representation capacity.

Status and analysis of exhibition lighting and illumination design

Viewed from design approaches, the lighting and illumination design procedures in the past are often based on established exhibition building spaces, and lacks early considerations to the design and plan of one important organic component of light, thus often resulting in the waste of energy lighting, inconsistency between exhibition contents and lighting effects, etc. Early cooperation between lighting designer and the exhibition building architect in design goal, space presentation and behavior shaping can develop a good interaction, in which the exhibition building architect is responsible for planning and designing of spatial organization and layout, while lighting designer is responsible for proposing specific requirements on light control, lighting illumination, image refracting visual effect and psychological effect and cooperating with the exhibition building architect to perfect the architectural design. Such two-way interaction seems more reasonable and easier to create appropriate exhibition design scenario comparing with the passive lighting design solutions.

Viewed from design process, lighting and illumination of traditional buildings are often designed after the completion of building construction. Such design model often gives architect a false sense that lighting design is secondary work. It is the "strawberry on the cake", which is the lastly considered but firstly gave up (when the budget is reduced). Furthermore, the clever application of natural light, visual adaptation, light glare problem, coloration and spiritual conception creation in the lighting and illumination often are viewed only as the selection of lamps and lanterns modeling. Such misunderstandings are caused by our ambiguous understandings on light concept.

Viewed from the design goal, the core goal of exhibition design is the information delivery, the core characteristic of exhibition design different from architecture space design. Museum spaces are used for culture and knowledge communication. Store spaces are used for the co-marketing of brands and products. Large world exposition is used for cultural exchange as well as reflection on science and technology. These space-based information transmissions can be concluded into the exhibition space design. This analysis revealed that exhibition space design and lighting and illumination design can achieve same goal: effective information transmission.

Viewed from design requirement, lighting and illumination design is the comprehensive design under the multidimensional requirement, including lighting equipment entities, lighting equipment amount and illumination quality standard. Meanwhile, it also implies the limitation and requirement of energy conservation and environmental protection. Different from material, shape and color requirements, lighting designers shall have clear aesthetic and functional goals on their design, understand the final diversified and complicated visual presentation effects, structure and construction requirements, and calculate energy consumption under the limitation of budget and technical parameters during the initial lighting and illumination design.

Teaching goal of exhibition lighting and illumination design

The primary curriculum content of "Exhibition Lighting and Illumination Design" includes introduction to light, natural light and basic principle of artificial illumination, relationship between light and vision and color, optical characteristics, and other theoretical knowledge. It transits from the basic principle of natural lighting in exhibition environment to the analysis of design approach, technical requirement and aesthetic significance gradually. It emphasizes on the deep analysis of artificial illumination, detailed introduction to the classification of common artificial illuminations as well as performance and characteristics comparison of different artificial illuminations. Furthermore, based on the disciplinary characteristics of exhibition design, it puts forward and analyzes the specific requirement and design procedure of lighting and illumination design in considering of exhibition contents of different natures, such as business show, museum, exhibition, etc. It aims to create teaching contents with deeper intrinsic logicality and sequentiality.

Based on the integrative interaction between lighting and illumination design and exhibition space, the design philosophy not only includes the natural lighting and artificial illumination design into design process at the very beginning, but also accomplish a series of design work in proper sequence from design consideration to design deepening and then to natural lighting and artificial illumination design. This, in return, give architects opportunities to revise, deepen and facilitate the exhibition architectural space design. The exhibition building, daylight opening as well as the illumination lamps and lanterns are designed and selected according to various contents in natural lighting design, such as light reflection, light direction and exhibition goods' requirement on light. In other words, lighting effect design is accomplished gradually with the exhibition architectural space design and the physical exhibition architectural space design, in return, will be deepened by the progressing of lighting effect design, thus achieving good interaction and virtuous cycle. This finally leads to the integration of aesthetics, functions and technologies in thinking.

During design process, students shall carry out a detailed analysis on different lighting and illumination design requirements of exhibition public space, information space, space for communication and reception, flow space, aesthetic and emotional space, and other different types of spaces. Based on the illumination requirements (e.g. universal lighting, spot lighting and situational lighting) of different areas, the natural lighting is controlled and applied, and artificial illumination is set and integrated according to the basic composition principle of optical system and professional

lighting design approach, thus finally achieving the goal of independent exhibition design by students.

Market research part requires students to survey the lamps market to understand the types and parameters of artificial lighting as well as their differences. They will begin to know various different types of lamps, such as filament lamp, halogen tungsten lamp, fluorescent lamp, low pressure sodium lamp (LPSL), high intensity discharge (HID) lamp, etc. They will know the luminescence principle, luminous efficiency, color rendering, color temperature, average service life, characteristics and other parameters of different types of lamps as well as their applicable space types. Meanwhile, students are required to making deep survey on local museum space, business space and exhibition space. Furthermore, they also have to study some excellent design cases and make detailed reports on their selection and application of artificial lighting systems for different exhibition spaces.

The software part requires students to master drawing techniques of real luminous efficiency simulation and output the design sketch through the cooperation of 3dmax and vary. They shall be able to simulate the real luminous efficiency by selecting corresponding lamps with delax lighting design software and output complete lamp report as well as power consumption. Besides, they shall be able to output a series of complete drawings through CAD software, including construction drawing of lamp circuits and electric circuit diagram, which are used for matching engineering exhibition design with practical construction.

To make a physical model with true exhibition lighting and illumination design, model making requires students to know the basic circuit access way and select proper circuit materials (e.g. equipments, wires, switches and converters) according to the practical requirement of luminous efficiency.

Curriculum practice of exhibition lighting and illumination design

Market survey

During the teaching of "Market Survey", the author led students to visit the Shanghai New Liuying Lamps Market and surveyed lamp types that are highly welcomed by customers. In addition, professional industrial experts were invited to offer a detailed explanation on the types, application ranges and prices of artificial illumination lamps. On this basis, the author led students to Shanghai Science & Technology Museum, Shanghai Museum, Suzhou Museum as well as other domestic excellent museums and exhibition halls in order to investigate and make a deep analysis on the practical application of lamps as well as various lighting approaches. The survey and analysis results were reported and represented through display panel.

Design basis

The initial curriculum design of "Exhibition Lighting and Illumination Design" accomplishes site planning, architectural modeling, traffic route, entrance and exit setting, function division, scale requirement, fire protection and water drainage. Students are asked to perfect the draft to architectural appearance molding, internal plane layout planning and simple design sketch drawing. This curriculum requires students to determine the overall lighting and illumination design idea according to their theme comprehension.

Design development

It requires students to think how to improve the architectural design through the illumination design development to enhance the visual effect of indoor exhibition and how to integrate the illumination equipments into the built environment through the optimal way. Additionally, it emphasizes on the design creativity. Finally, the teacher-student discussion enables students to have a clear understanding on the concept of lighting and illumination design. Students are required to analyzing the illumination requirement differences among different functional areas. For example, students have to analyze whether it is necessary to introduce natural light into the public space and how to control the natural lighting effectively through various techniques; whether the information space has satisfying illumination of key areas and appropriate space-environment luminance ratio. In addition, students have to design key and subordinate luminous efficiency in the flow space based on the comprehensive consideration of illumination control and security. In artistic conception design, students have to analyze various visual presentation factors like color temperature and illumination and think how to create appropriate harmonious exhibition space environment.

Lighting and illumination analysis and design

The design development pays superior attentions on students' effective representation of their designs. The design representation requires students to communicate with teachers through drafts firstly, emphasizing on the artistry of designed shape as well as illumination efficiency requirements of different areas. Furthermore, students have to analyze lighting systems according to different requirements through plane and three-dimensional drafts and accomplish initial lamp selection. Teachers will teach in accordance of their design content, focusing on analyzing the artistry of their designed shapes, evaluating whether the selected lamps are appropriate and helping students to enrich weak knowledge of artificial illumination lamps and deepen their designs.

The communication based on design draft requires students to draw visual design sketch with stronger luminous efficiency expression by using 3dmax and vary. This not only trains students' independent design and sketch drawing ability, but also evaluates their design style, construction structure, security, color matching and other comprehensive requirements according to their design sketches. After finishing the design sketch drawing, students are asked to output complete circuit diagram and lamps arrangement plan through CAD software. During this period, teachers will be mainly responsible for helping students in solving some technical problems, such as lamps circuit layout and electric circuit arrangement. Furthermore, students have to select lamps practically and output complete lamps report through delax software.

Model making and representation

Model making procedure: make the bottom light box of model according to determined size and then punch holes at the base for connection. Connect the small LED lamps in series connection to the base and then connect to the main switch after the power supply is installed. Finally, arrange the outdoor scene and indoor furniture. The bottom lamp tube is responsible for the theme illumination of the whole exhibition hall. Meanwhile, showcase models in the exhibition hall are made and connected with lamps with every component fixed well. Finally, all models are perfected.

conclusion

The exhibition lighting and illumination design curriculum targets at the achievement of multidimensional goals. In design platform, the exhibition space design and lighting and illumination design interaction mode enable students to connect the initial luminous efficiency design with achievements of previous curriculum, and further develop and deepen these achievements. In design idea, it enables students to have a clear idea on the design theme, luminance, lighting and expected lighting effect of the exhibition content at the very beginning. In technical requirements, it requires students to investigate the lamps market, including lighting types, parameters, differences, etc. In software, students can use software to simulate real lighting and luminous effect and make practical lamps report. Finally, the achievement is represented through a model entity with lighting and illuminating devices.

The Exhibition Lighting and Illumination Design curriculum for the Exhibition Design Major of Department of Industrial Design of Hubei Institute of Fine Arts requires to be established in "weekly" curriculum system. Teachers emphasize on different aspects in different teaching weeks. The teaching is supplemented and design is facilitated by theory, design, representation and implementation. It not only guides students to establish the two-way interaction design idea of exhibition space design and exhibition lighting and illumination design, but also trains their comprehensive analysis and problem solving ability in exhibition lighting and illumination design field, aiming to lay a solid foundation for exhibition design discipline, improve the exhibition design talent quality, facilitate the design quality of exhibition industry and strive to develop wide-scope and interdisciplinary exhibition design talents.

Keywords: Petrochemical enterprises, economics, safety investment, safety benefits.

Abstract. Petrochemical industry plays a vital role in the world's economic development. However, companies are still faced with a great number of economic loss and a lot of safety investment activities, thus, it needs to study and discuss the theories and methods of safety economics so as to guide economic activities and make enterprises gain the greatest safety benefits. This article is in the view of economics and from the perspective of safety investment, which analyzed the importance, characteristics, categories of safety investment and establish a safety investment model. Companies should seek a way to make full use of economic resources and carry out different safety investment policies according to different production methods.

Introduction

With the emergence of the first oil well in the United States on August 29th, 1859, it lifted the curtain on the world oil industry and became the beginning of modern oil industry. The oil industry is a high-risk and technology intensive industry. It has an extremely important role in the process of the development of the global economy. However, the oil industry is a dangerous industry which is easy to have accidents, such as poisoning, fire and explosion. Once the accidents happen, there will be a large number of deaths and injuries and huge property losses.

Safety means a stable and relatively predictable environment. People and groups won't be interrupted or injured and don't need to worry about interference or damage when they chase for their goals in this kind of environment [1].

According to the 'The annual report on the Boao Forum for Asia in 2012', China National Petroleum Corporation was still at the top of the list and Sinopec was the fourth. From that we can draw a conclusion that China's petroleum and petrochemical industry is developing rapidly. However, safety needs to be paid special attention on the back of the rapid economic development without ignorance. A case study of hazardous chemicals of Chinese petrochemical enterprises, there were 813 accidents and 1360 people were killed between 2004 and 2010 (Fig. 1). The number of dangerous chemicals accidents and deaths was on a declining line, which was linked closely with safety investment.

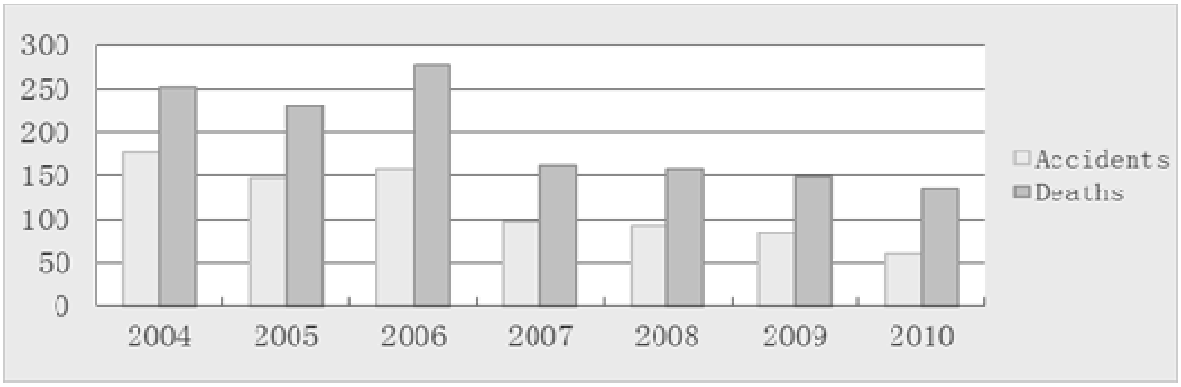

Fig. 1 Accidents and deaths of dangerous accidents

Overview of safety investment

Safety investment is the sum of all human, material and financial resources. The benefit of safety investment is different from common investment, which can't be directly reflected in the improvement of the production and quality. There are not obvious incomes, but in the process of production and business operation and it is reflected in the safety investment which can guarantee the normal and continuous production. Safety investment does not directly increase the product value, only to avoid the value loss caused by unsafe conditions [2].

From the perspective of economics, safety has the function and role of avoiding, reducing the consumption and loss of accidents, maintaining the productivity and guaranteeing the social and economic wealth [3]. Also, from the perspective of economic development, if the safety in production is good, then the performance of enterprises will be better, employees' working and living conditions and the order of production will be normal so as to give play to social and economic benefits.

Model of the safety benefits

The relationship between benefits and safety investment is a monotonically increasing function. With the increase of safety investment, the benefits of companies increase accordingly [4]. Through the analysis of companies' production and operation data, we can get the relationship between safety investment and safety benefits (Fig. 2).

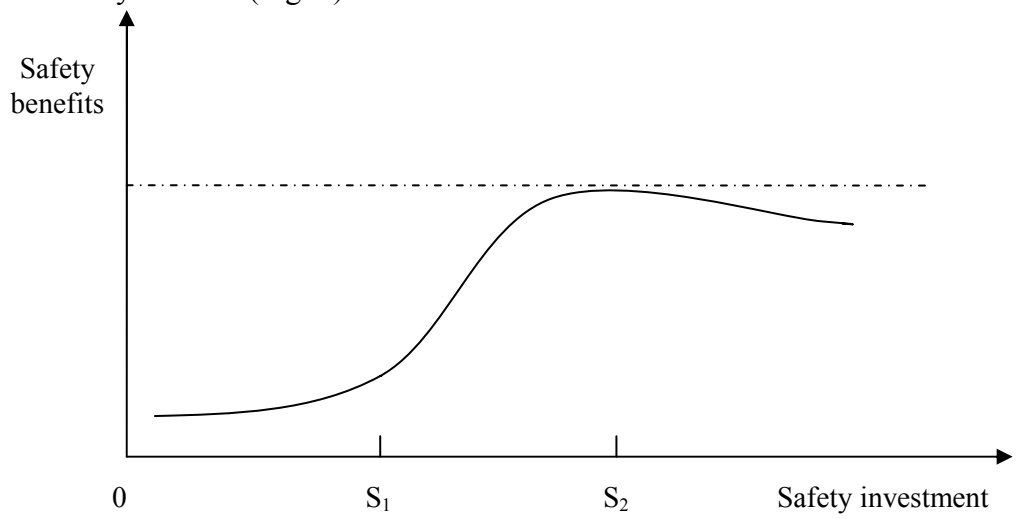

Fig. 2 Relationship between safety investment and safety benefits

From the safety investment and safety benefits curve, the influence of safety investment can be divided into three regions.

(1) $(0, S_1)$ is in the name of safety instability area. Though there is some safety investment, but the safety condition and benefits of companies can't be guaranteed. S_1 is called safety instability point.

(2) (S_1, S_2) is in the name of safety improvement area. If safety investment is increased in this region, the improvement of the safety state will improve the companies' benefits obviously. S_2 is called best safety point.

(3) $(S_2, +\infty)$ is in the name of overflow area. If companies increase the safety investment without limit, though the safety condition is very good, the benefits of the enterprises will decrease.

Thus, there is a limit to how much of the safety investment [5]. When the safety cost and the accidents losses achieve the minimum, the investment is the best point at this time in theory. But in some cases, even though there is a lot of safety investment, it won't ensure that no accidents may happen. As soon as the safety level reaches an acceptable level, the safety investment should be combined with economic benefits. The safety investment is not the bigger the better and different safety investment plans will generate different effects. The effectiveness of the safety investment can be determined according to the benefit-cost ratio of economics (Eq. 1, 2).

$$V=B/I \tag{1}$$

$$E = E_1 + E_2 + E_3 + E_4 - E_5 \quad (2)$$

V: Effectiveness of safety investment;
B: Safety benefits;
I: Safety investment;
E: Economic benefits of the safety investment;
E_1: Direct economic benefits which are created by reducing accidents;
E_2: Indirect economic benefits which are created by reducing accidents;
E_3: Economic benefits which are created by reducing the safety investment;
E_4: Potential economic benefits;
E_5: Safety investment.

Characteristics of the safety benefits

Hysteresis. The function of safety in reducing the casualties and property losses can't be reflected at the time of the security operations, but shows its value and function at the time of the accidents. Safety investment can't be done when accidents occur. Instead, safety investment should be done before in case of accidents, so safety has the characteristic of hysteresis.

Indirectness. The economic benefits' value of safety is reflected by reducing the casualties and property losses. On the one hand, the losses of society, enterprises or individuals can be eased which realize the indirect value. On the other hand, due to the protection of the production technology or equipment, the production can be added value. Most of the safety investment is to realize its use value, such as the measures to reduce the casualties and losses. However, the investment of safety education, health care and labor protection, environmental protection and other aspects can reflect the social benefits of society, so this kind of investment belongs to consumption. Its role is indirect relative to the safety investment.

Potential. The economic benefits of safety measures are not the direct performance from their functions, but behind the potential in the process of the safety [6]. One of the main goals of safety is to ensure people's safety and health, but the value of people's safety and health is hard to be measured by currency. Safety can make people safer and protect the economic conditions and resources of human beings.

Categories of safety investment

Safety investment refers to the cost which is related to safety, and it is the general term of the economic activities and resources which are used to guarantee the business operation in peace [7]. It may include human resources, material resources, financial resources, space and time, etc. In the implementation process of safety investment, Fig. 3 shows the steps of safety investment.

Categories of safety investment include engineering project investment, labor protection investment, safety education investment, safety management investment, emergency rescue investment, insurance investment, accident investment and other necessary investment.

Summary

The realization of safety needs the economic supports and safety is the product of people's economic development in essence. Specific economic level determines the specific safety level. Safety is not a direct substance production. The value of safety is reflected by reducing the casualties, property damage, environmental damage and social impact. Safety shows its value and function at the time of accidents. The characteristics of safety investment result in the petrochemical industry for safety investment is not paid enough attention.

From the point of safety economics, this article analyzed the safety investment of petrochemical enterprises. The safety investment needs to meet the objective requirement of the production

technology and the most effective use of safe resources should be sought. Different safety investment policies are carried out according to different production technology.

National government and regional government should strengthen the legal system, establish the regulatory system and urge the safety investment of petrochemical enterprises. Companies which ignore safety investment and cause casualties should impose economic sanctions. The amount of pensions paid for employees should be raised to urge petrochemical enterprises to increase investment in safety. Safety investment can guarantee the personal security, decrease the accident rate and raise the international image and social image of countries, governments, enterprises and organizations. It also adapts to the needs of the national economy and social development, reveals the safety investment of companies and promotes the development of labor protection utilities, security, science and technology.

Analysis of Digital Electronic Teaching in Higher Vocational Colleges ——Cultivating and Stimulating Learning Motivation

Yanhong Li
Shandong Water Polytechnic, Shandong 276826,China.
liyanhong_2008@126.com

Keywords: Digital Electronic, Teaching, Learning Motivation.

Abstract. Digital Electronic Technology is a very important professional foundation course in higher vocational college, especially those majors in mechanical or electrical engineer. How to arouse students' enthusiasm and initiative in every possible way, and make them pleased to acquire knowledge, it is the major research topic. So the key to success in teaching is the cultivation and simulation of learning motivation.

Introduction

With the development of digital circuits, digital technology has penetrated into every field of our daily life. Digital electronic technology is a kind of computer, communication and electronic information, such as basic required courses for professional public technology. The main purpose of this course is to enable students to learn the basic principle of digital logic circuit and the basic circuit, which is helpful to grasp system analysis method, the design method of digital logic circuit and its application. It is necessary to learn and master the modern electronic technology. Therefore, how to arouse student's enthusiasm and initiative, make students master the knowledge happily, cultivate and stimulate their learning motivation is a key factor to the success or failure of the teaching.

1 The Importance and Necessity of Cultivation and Simulation of Learning Motivation

Learning refers to stimulate students individual learning activities, maintain the learning activity which has been caused, and behavior towards a certain learning objective of a process or internal inner psychological state. If students want to study hard, learning enthusiasm, initiative has a lot to do. Once students have developed an interest in digital electronic technology course, they will show a strong desire for knowledge and concentration and classroom efficiency naturally in the classroom. Therefore, the teacher should pay attention to digging depth from the attach importance to cultivate and stimulate students learning motivation, let the students change from passive learning to active learning.

2 Cultivating and simulating learning motivation in Digital Electronic Technology Teaching

2.1 Stimulating Interest and Maintaining Curiosity

Interest and curiosity are the most core part of the learning motivation. Cultivating the students learning interest is the first task of teaching no matter in what stage of learning. Where there is a possible, to prove to students that the learned information is useful. Creating problem situations to inspire students thirst for knowledge and curiosity is a kind of very effective method. Creating problem situations refer to provide an opportunity for students to question and engage in activities, to explore the answers to questions, certain efforts are conducive to successfully solve the problem of learning materials, conditions, and practice. Effective teaching is the key principle to form a kind of atomosphere to make the students understand a little knowledge, uncertain problem situation resulting conflicts, doubts, surprises and then arouse the greatest intellectual curiosity and interest in learning, in this way, a desire and intention of learning are brought out.

In order to arouse their interest in learning and maintain curiosity for content, a teacher wants to import teaching meticulously and stimulate students thirst for knowledge. There are many import methods of teaching, but the most common and obvious effect is the instance of import design method. When they talk about the sequential logic circuit, for example, triggers section, using PPT for presentation quiz answer after the video program, putting forward the problem which is similar to a few players seem to be press the buzzer at the same time , but why only one contestant vies to answer the first success? Let them think about the problem, and then draw out the main content of the lecture. Such imports can not only stimulate the students curiosity and thirst for knowledge, but also make students believe that the importance of content and interesting, so as to cultivate the students learning motivation.

2.2 Setting the right goals

The law of learning motivation is important. When the target is set by yourself, rather than when it is set by others, oneself often pay more efforts. Such as, before digital electronic technology experiment, let students expect the length of time for myself under the situation of guaranteed accurate every time. When the goal is set, teachers can discuss with students the targets set by the implementation situation, the probability of success or failure, respectively, so that they set suitable goals for themselves. Finally, the teacher wants to praise students in goal setting and its implementation in the experiment summary. Throughout the semester, the teacher will be surprised, it can not only makes students learn digital electronic technology actively, but also cultivates their ability to innovate in the course and to achieve the purpose of fostering a good learning motivation.

2.3 Developing Appropriate Self-efficacy

After the students have the corresponding knowledge skills, self-efficacy has become the decisive factor of their behavior. Self-efficacy is put forward by bandura in the 80s, who makes a subjective judgment of behavior success or not by oneself. It is the individual of their ability to perform a behavior of speculation and judging. The factors influencing self-efficacy are personal behaviors of success or failure experience, substitute experience, verbal persuasion,etc.Many students especially students whose learning results are bad, they are skeptical about their ability to learn, so they often show the low self-efficacy level. In this part of the students, such as, when the teacher asks questions of kano logic function graph reduction problem in class, she can give some hints. Try to construct the interpretation of each chapter, each problem, pay attention to guide students to summarize the rules. For example, in digital electronic technology on karnaugh map reduction, this content in addition to the book of methods, teachers can guide students to summarize some effective laws.

For example: in the four variables f (A, B, C, D) in the karnaugh map, m0, two minimum sum of ml can get rid of one variable. Using the method in the book are two algebraic method according to the sum of the smallest reduction, may guide the students to observe karnaugh map m0 and ml minimum two items of the small squares in A, B,C three variables constant, only the variable D in the corresponding box as the variables, m0 in ml box corresponding to the original variables, that is to say, in A, B, C, D four variables only D variable has changed, so D variable elimination in two minimum operation.

For some more complex expressions, in the reduction or even require students to use some skills, if using this method is more helpful to show its unique superiority. Such as expression for reduction，$\overline{F = AC+\bar{A}BC+\bar{B}C + AB\bar{C}}$，using the concept of collection, we can still according to fill out directly by the expression method of karnaugh map. Due to logic is equivalent to complement operation, the corresponding collection of the first item $\overline{AC+\bar{A}BC+\bar{B}C}$ is the type of complement for the collection of the item $AC+\bar{A}BC+\bar{B}C$. So the item can be found out $AC+\bar{A}BC+\bar{B}C$ place in the karnaugh map, fill in its complement position 1. And with the second

set, to get the same result. , due to not be involved in the concept of fill 0 here is only related to the use of collection, the students are familiar with the knowledge, easy to grasp.

So it is convinced that everyone has the ability to learn, let them gain continuously successful experience, and improve the level of self-efficacy. At the same time, teachers can also be used to change students attribution and train their ability to learn the wrong judgment, judge the right self-efficacy formation and learn motivation stimulated the nature.

2.4 Attribution Training

Attribution is named after behavior, refering to the relevant information: the causes for the clues to the behavior of individuals are according to speculate and judging process. Attribution is a universal thing that human need. Everyone has a behavior from its own experience summing up out the connection between the reason and its behavior of views and ideas. To change students' incorrect attribution and improve learning motivation can be listed from the two aspects: the first one is "effort attribution", no matter success or failure is due to to hard or not. The second is "reality attribution ", which guides the student to do a reality for some specific problems of attribution.

As they talk about the shift register, teachers can let the students design a loop control of neon lights, such as the "elixir of love" four word cycle light, get different combinations, or "good moon flowers, take a full moon, for good month circle". With real life together, the design of the students enthusiasm is very high. Finally, according to the design of the students, teachers guide all students to analysize, thus receiving the recognition from the students. Students like this way, from which they can not only can feel real mastery of book knowledge, but also find out the problem of cultivating their independent thinking ability at the same time. At the same time, students see their successful product design, which can produce a strong sense of achievement.

In the process of teaching, the author once met a student, she thought she had low intelligence. However, after communicating with her, it is as a result of her learning method which is not correct. Before this attribution training can change students' error of judgment and its advantage, find out the problem and point out the ways to solve these problems. The students can not only get knowledge, but also gain confidence. This will better suit the remedy to the case, to stimulate students' learning motivation from the aspects.

3 Conclusion

Digital electronic technology is a professional foundation course which is abstract and difficult to understand. In order to improve the classroom efficiency, the author explores actively from the aspects such as the cultivation and stimulation of learning motivation in the last three years of the digital electronic technology teaching practice, all these have got some achievements, but it’s only a preliminary attempt, there are still many problems that need to be further explored.

Keywords: project-driven, course assessment, network operating system

Abstract: Project driven and course designed teaching and examination mode is a kind of brand-new teaching and examination mode, it is a student oriented mode which focus on how to train highly skilled people in practice courses. Combined with course《Win server 2008 network operation system》,below paper give a more detailed and comprehensive introduction for this teaching mode, based on which writer would like to popularize this teaching method with specific demonstration.

Introduction

"Project driven and course designed" teaching and examination mode is a new mode for both teaching and examination which is combined with traditional project teaching mode, case study teaching mode and the new course design criterion. The core for this mode is "student oriented, attach importance to students' proactive knowledge exploring, and also the initiative to find the relationship between the project and knowledge"[1]. Meanwhile, the mode also advanced new assessment method for practice course, which is not purely written examination but is assessed via the quality of course designed by student or the task finished by student, which can reflect the degree how student grasp the knowledge, through all above this mode well achieves the aim to train high quality talent with "qualification, flexibility and being user-friendly" [2].《Win server 2008 network operation system》can well apply this mode, thus can well combine the strongpoints for course and teaching.

The link between the course and actual enterprise commercial activities

The technique《Win server 2008 network operation system》covered can well can be applied to many areas, such as computer network project design, management and maintenance, guide for MCSE, network management, server installation, configuration, management, local area network management, network maintenance, etc. Thus the knowledge point for this course can be further divided from the actual enterprise business needs, which means enterprise project oriented course design.

Specific project conclusion and division

Taking the network building and management as starting point, the project as carrier, living the project oriented thinking, focusing on project design, we combine all the knowledge point of 《Win server 2008 network operation system》 with practice, with the theory knowledge being the fundamental for practice, to avoid long term boring theory teaching that may hurt the student's learning interest, we develop simple practice to attract the spontaneous question from students, then

explain main theory and properly analyze. This helps students deeply understand the theory after interesting practice.

Project division. We divide the theory and practice mentioned in《Win server 2008 network operation system》to 13 items listed in below table(Table 1：Project division example):

Table 1：Project division example

Item	Item description
Item 1	Installation and Planning for Windows Server 2008
Item 2	Hyper-V server installation and set up
Item 3	Deploy and manage Active Directory domain service environment
Item 4	Manage user account and group
Item 5	Manage file system and shared resource
Item 6	Set up and manage basic disk and dynamic disk
Item 7	Set up and manage printers
Item 8	Set up and manage DNS server
Item 9	Set up and manage DHCP server
Item 10	Set up and manage Web and FTP server

Task analysis for each item. Below please find the specific tasks for each item:

- Item 1:Installation and Planning for Windows Server 2008
  Task 1: Install Windows Server 2008 R2 with CD.
  Task 2: Set up Windows Server 2008 R2
  Task 3: Add and manage administrator role
  Task 4: Use the management and control platform for Windows Server 2008
- Item 2:Hyper-V server installation and set up
  Task 1: Install Hyper-V role
  Task 2: Uninstall Hyper-V role 2
  Task 3: Establish visual machine
  Task 4: Config the property for visual machine
  Task 5: Install operating system for visual machine
- Item 3:Deploy and manage Active Directory domain service environment
  Task 1: Create the first domain
  Task 2: Install additional domain controller
  Task 3: Transformation service role
  Task 4: Backup and resume activity directory
- Item 4:Manage user account and group
  Task 1: Create local user account
  Task 2: Set up the property for local user account
  Task 3: Remove local user account
  Task 4: Manage the group account in domain
- Item 5:Manage file system and shared resource
  Task 1: Set up resource sharing
  Task 2: Visit network shared resource
  Task 3: Use Volume Shadow Copy
  Task 4: Succeed to and stop NTFS authority

Task 5: Copy and move file and file folder

- Item 6:Set up and manage basic disk and dynamic disk
  Task 1: Manage basic disk
  Task 2: Get to know dynamic disk
  Task 3: Create dynamic disk volumes
  Task 4: Maintain dynamic disk volumes
- Item 7:Set up and manage printers
  Task 1: Install printer server
  Task 2: Connect to shared printer
  Task 3: Manage printer server
- Item 8:Set up and manage DNS server
  Task 1: Understand the concept and theory for DNS
  Task 2: Add DNS server
    Sub task 1：Establish the DNS server needs and environment
    Sub task 2: Install DNS server
  Task 3: Deploy DNS zone for main DNS server
    Sub task 1：Create a forward main zone
    Sub task 2: Create a reverse main zone
  Task 4: Config the DNS client and test the primary DNS server
    Sub task 1：Config the DNS client
    Sub task 2: Test DNS server
    Sub task 3: Manage DNS client cache
  Task 5: Deploy the assistant DNS server
    Sub task 1：Establish the assistant DNS server needs and environment
    Sub task 2: Establish zone transfer function on primary DNS server
    Sub task 3: Install DNS service on assistant DNS server and create assistant area
    Sub task 4: Config DNS client test on assistant DNS server
  Task 6: Deploy subdomain and delegation
    Sub task 1：Establish the subdomain and appointment needs and environment
    Sub task 2: Create subdomain and its resource directory
    Sub task 3: Zone delegation
- Item9:Set up and manage DHCP server
  Task 1: Get to know DHCP
  Task 2: Set up and manage DHCP server
  Task 3: Set up DHCP relay agent server
- Item 10:Set up and manage Web and FTP server
  Task 1: Get to know the service provided by IIS 7.0
  Task 2: Set up and manage FTP server
  Task 3: Set the AD isolation user FTP server

Team division and Project implementation

Teachers must ensure they well know every student in terms of both life and leaning, and must make sure to make good balance among teams in terms of team member's learning ability and interest. Teachers must assign 1 to 2 foals for each team, the foals need to monitor and reflect the learning status of his/her team and also communicate duly with teachers for the issue they encountered.

In this mode, teachers is not the one who is instructing everything and explaining everything, teachers need to know clearly about the plan, progress, issues for each team and give support to assist student to find solutions for the issues they encountered. Teachers must ensure to be well prepared for all kinds of issues for each team he/she can foresee, this is to avoid the embarrassing situation that even teacher do not know how to deal with the issue. Besides, the students' lacking initiative and creative which was resulted in by traditional education mode is also a barrier for the new mode, in order to avoid this, students must be required to establish detail project plan independently, meanwhile organize both life and learning all by themselves in a specific period, and most important is that to present the project achievement clearly and specifically [3].

Establish course assessment criterion

Teachers need to keep close monitor the completion status, the degree that student grasped knowledge, the interest, adjust the project task details and difficulty. For the difficult knowledge, teachers need to add practice explanation and demo session, this is to avoid teaching stopped due to knowledge is too difficult.

As to <Win server 2008 network operation system>, it is difficult to establish overall assessment criterion. The assessment is mainly referred to periodical project report and usual performance of individual student.

Summary

With the new mode applying to course《Win server 2008 network operation system》, student's learning interest and thinking eager is greatly inspired, meanwhile student's learning confidence is also improved significantly, all these really reflect the characteristics for vocational education. Students can be very efficient, have strong learning ability and also great adaptability to different environment.

Through this new mode, purely classroom course is transferred to on site training and practice which can gain real experience and ability, students grasped the solutions for the possible issues they may encounter in future work, meanwhile, teaching quality and comprehensive professional quality can be fully improved. And the new mode also inspires teachers to explore for new knowledge and enrich teachers with actual enterprise experience.

Keywords: fuzzy comprehensive evaluation method, Analytic Hierarchy Process, SWOT analysis, competitive strategy

Abstract: This paper attempts to employ the matrix of Strengths, Weaknesses, Opportunities, Threats(SWOT) to establish an evaluative index system for software enterprises in Jilin Province. The SWOT analysis is performed in combination with the Analytic Hierarchy Process (AHP) to determine the relative weights of various criteria in the analytic hierarchy as they are related to the overarching goal. The ultimate assessment of the developmental status of those provincial IT enterprises from the local (departmental/segmental) to the global (corporate/industrial) level will then be derived by applying a fuzzy comprehensive evaluation matrix in accordance with the principle of maximum associations. This approach promises to overcome drawbacks commonly found in conventional hierarchical analyses, where frequent adjustments and tests are often required to make results from judgmental matrix consistent. Examples with concrete analytic results have shown that this innovative, synthetic method is of promising guiding significance to corporate strategic formulations.

Introduction

The competitive strategy of a corporation involves processes through which a firm rationally allocates and matches its internal and external resources to develop and implement business plans in order to obtain a competitive edge. Typically, formulators of such strategies use the SWOT analysis to obtain qualitative assessment of strengths and weaknesses as well as opportunities and threats coming from both within and without the firm in quest for a best-fitting developmental strategy. However, a vague description of the competitive position, in fact, can be finally formed based on this method, so that the conclusion from such analyses tends to have some differences from the reality[1]. In recent years, many researchers seek to add quantitative rigor to such qualitative evaluations by applying fuzzy mathematics to analyses of multi-variate things or objects for overall assessment, which has solved certain analytical problems traditionally deemed as being vague. However, it is difficult to quantify [2,3]. In this paper, we attempt to establish an evaluative index system as it pertains to software companies in Jilin Province based on the SWOT analysis, which is carried out in combination with a multi-level fuzzy decision-making method to solve the problem of their strategic choice.

1. Formulate the Evaluation System

The SWOT analysis is carried out on the provincial software enterprises in Jilin to examine their internal and external environment, in order to construct an evaluation index system to facilitate choices in corporate competitive strategies.

(1) Construct an SWOT analytical matrix [4]

In this paper, the results of the SWOT analysis of the software enterprises in Jilin from the lens of the regional economic development are summarized in the matrix shown in Table 1.

Table 1 The matrix of the SWOT analysis for the development of the software enterprises in Jilin

Strength（S）	Weakness（W）
1.the advantage of the region (S_1) 2.the advantage of the talents (S_2) 3.the advantage of the industry (S_3) 4.the advantage of the base (S_4)	1.optimization required for the industry environment (W_1) 2.the scale is so small for the whole software industry (W_2) 3.weakness in the creative ability for the software company(W_3) 4.it is incomplete for the support of the oversea's market (W_4)
Opportunity（O）	Threat（T）
1.Strategy for the Pilot Changchun-Jilin-Tumen Open-up & development zone (O_1) 2.Enhancing the support of the government(O_2) 3.Embedded software as the represent of the automotive electronics (O_3) 4.Wide prospect of outsourcing market in export for software(O_4)	1.Internalization of international competition (T_1) 2.Existing problems in the construction of the software park(T_2) 3.Serious brain-drain，the structural contradiction of industry is prominent(T_3)

(2) Establish the indexing system

In light of the specific circumstances concerning software development in Jilin, the developmental strategy for the provincial software companies (G) is defined as the overarching goal, and S , W , O , T are referred to as the first-level (parent) indicators, whereas specific factors S_1 , S_2 , S_3 , S_4 , W_1 , W_2 , W_3 , W_4 , O_1 , O_2 , O_3 , O_4 , T_1 , T_2 , T_3 represent secondary (child) indicators respectively.

2. Determine the Relative Weights of Respective Indicators

In this paper, we use AHP to determine the relative weights of the differentially leveled indicators, where the pairwise comparisons are undertaken on the same-level indicators for their relative importance to the parent indicator at the upper level to form a judgmental matrix. A characteristic vector will then be identified for each group of indicators, and its consistency will be tested accordingly.

(1)Construct the judgmental matrix

Based on the index system, the Delphi method is taken to form the judgmental matrix - each for factors S , W , O , and T respectively - following steps outlined below:

$$S=\begin{pmatrix} 1 & 1/3 & 1/3 & 1/2 \\ 3 & 1 & 1/4 & 2 \\ 3 & 4 & 1 & 4 \\ 2 & 1/2 & 1/4 & 1 \end{pmatrix},\quad W=\begin{pmatrix} 1 & 1/2 & 1/3 & 1/3 \\ 2 & 1 & 1/2 & 1/2 \\ 3 & 2 & 1 & 3 \\ 3 & 2 & 1/3 & 1 \end{pmatrix}$$

$$O=\begin{pmatrix} 1 & 1/2 & 1/5 & 1/3 \\ 2 & 1 & 1/3 & 1/2 \\ 5 & 3 & 1 & 5 \\ 3 & 2 & 1/5 & 1 \end{pmatrix},\quad T=\begin{pmatrix} 1 & 1/3 & 1/3 \\ 3 & 1 & 1/2 \\ 3 & 2 & 1 \end{pmatrix}$$

(2)Calculate the weight for each indicator

The characteristic vector of the matrix is obtained through the square root method, which is then normalized for consistency check, as shown in Table 2.

Table 2 The weight of all model and the result of the consistency check

Strength		Weakness		Opportunity		Threat	
Weight W_1	Consistency check	Weight W_2	Consistency check	Weight W_3	Consistency check	Weight W_4	Consistency check
0.1003 0.2212 0.5400 0.1385	$\lambda_{max}=4.2216$ $CI=0.0739$ $CR=0.0830$	0.1038 0.1789 0.4576 0.259	$\lambda_{max}=4.1649$ $CI=0.0550$ $CR=0.0618$	0.0798 0.1424 0.5766 0.2012	$\lambda_{max}=4.1777$ $CI=0.0592$ $CR=0.0666$	0.1396 0.3325 0.5278	$\lambda_{max}=3.0536$ $CI=0.0268$ $CR=0.0515$

3. Construct the Evaluation Model

(1)Determine the field of characteristic factors influencing the evaluation

Based on the literature review, we divide the collection of comments on qualitative indicators (V) into five grades in terms of importance, namely: {not important at all, not important, general, fairly important, very important}, with their corresponding value to be assigned according to Table 2, as shown in Ref. 5. The set of factors is obtained by synthesizing expert opinions both at home and abroad. The four fuzzy relational matrix for the factorial modules represented by S, W, O, T are denoted as U_1, U_2, U_3, U_4 respectively , with their specific forms as follows:

$$U_1=\begin{pmatrix}0.04 & 0.09 & 0.43 & 0.26 & 0.18\\ 0.08 & 0.11 & 0.24 & 0.37 & 0.20\\ 0.07 & 0.10 & 0.14 & 0.37 & 0.32\\ 0.03 & 0.08 & 0.19 & 0.41 & 0.29\end{pmatrix} \quad U_2=\begin{pmatrix}0.03 & 0.05 & 0.12 & 0.46 & 0.34\\ 0.10 & 0.16 & 0.23 & 0.30 & 0.21\\ 0.05 & 0.10 & 0.30 & 0.42 & 0.13\\ 0.06 & 0.18 & 0.34 & 0.27 & 0.15\end{pmatrix}$$

$$U_3=\begin{pmatrix}0.05 & 0.12 & 0.41 & 0.24 & 0.18\\ 0.20 & 0.35 & 0.19 & 0.17 & 0.09\\ 0.08 & 0.12 & 0.18 & 0.34 & 0.28\\ 0.06 & 0.18 & 0.34 & 0.27 & 0.15\end{pmatrix} \quad U_4=\begin{pmatrix}0.07 & 0.09 & 0.13 & 0.20 & 0.51\\ 0.06 & 0.10 & 0.15 & 0.41 & 0.28\\ 0.05 & 0.09 & 0.14 & 0.19 & 0.53\end{pmatrix}$$

(2)Determine the degree of index memberships

To multiply the relative weights $W_i(i=1,2,3,4)$ assigned to the four factorial modules used in the SWOT analysis by $U_i(i=1,2,3,4)$ according to the formula $B_i=W_i\cdot U_i(i=1,2,3,4)$, we get the comprehensive evaluation results for the software enterprises in Jilin, as shown in Table 3.

Table 3 The subordinated level of one grade indicator

One grade indicator	not important at all	not important	General	fairly important	very important
S	0.0637	0.0984	0.1981	0.3645	0.2753
W	0.0595	0.1263	0.2792	0.3637	0.1713
O	0.0907	0.1648	0.2320	0.2937	0.2188
T	0.0561	0.0933	0.1419	0.2645	0.4440

(3)Get the comprehensive evaluation results

The final results of the modular evaluations as they pertain to software enterprises in Jilin Province are computed with the assistance of the fuzzy comprehensive evaluation rating method by assigning values to the above-mentioned five grades of importance based on the formula $G_i=B_i\cdot V_i^T$: i.e., V_i ={not important at all, not important, somehow important, fairly important, very important}, where (i=1,2,3,4). The calculation also takes into consideration the actual situation of those enterprises. The final results are presented as follows:

(4)Select strategic options for business development for Jilin software enterprises

In this paper, we use the coordinate graph to present the SWOT analysis[6], where a total of four alternative strategies are plotted, namely the Pioneering Strategy, the Reversing Strategy, the

Defensive Strategy and the Stabilization Strategy. Based on the coordinate data, the area defined by the combination of Advantages and Opportunities is calculated to be 12.4890, which represents the largest area. Therefore, the option represented by the first quadrant should be selected as the strategic objective, namely the Pioneering Strategy. Meanwhile, the software companies in Jilin must pay attention to the Stabilization Strategy represented by the combination of Opportunities and Disadvantages, in order to seize opportunities like implementing the strategy for the Pilot Changchun-Jilin-Tumen Open-up & Development Zone, so as to avoid internal industrial weaknesses, and to achieve the sustainable development of the software enterprises in Jilin.

4.Conclusion

This paper reports on an objectively-and-faithfully-conducted SWOT analysis of the development of the software enterprises in Jilin Province. The analysis has been carried out in combination with AHP and the fuzzy comprehensive evaluation method to assess strengths, weaknesses, opportunities and threats confronted by the software enterprises in Jilin. Based on the final results of the evaluation, it is recommended that the Pioneering Development Strategy is taken by the provincial software companies to pursue their business development.

Keywords: Low carbon development path; Multiagent network structure; Carbon tax; Coal industry chain

Abstract. Based on coal industry chain features and decision-making behavior features, considering the marketing environment changes caused by the carbon tax, models are separately set up specific to the whole industry chain and different individuals' optimized decision-making differences, and the individual decision-making target is taken as a connecting link between the preceding and the following for the variable to integrate the model into a double-layer programming model. The results show that the model can reflect the influence of the individual selection of the industry chain on the overall interests and direct the decision-making.

Introduction

In related studies at present, only a few researches have been made into the influence of self-management from different individuals on the whole coal industry chain .Under the operating mechanism of large coal enterprises in China at present, different levels of the industry chain show a behavioral tendency ---longitudinally, they are mutually related to each other and supposed to provide uniform services for the overall interests of the enterprises, while in the internal management of the enterprises, separate settlement is always required in each level to pursue maximum individual benefits. All of these reflect the "two-sideness" of each level in the industry chain which not only represent the benefits of the industry, but also pursue the individual benefits; the whole industry chain represents the features of multiagent collection. Especially under the background of low carbon development required by the present society, the whole industry chain always needs product adjustment by individual enterprise, and they even have to give up part of the high-profit products in order to meet the carbon discharge requirements, which further deepens the contradiction between the whole industry chain and the individuals. Therefore, seeking the relationship between the enterprise individual development of each level in the coal industry chain and the overall development of the industry chain helps the industry adjustment and industry structure optimization, so as to realize the overall upgrading of the coal industry.

Modeling and analysis

Modeling assumptions. Before modeling, the complex real world should be firstly simplified to be convenient for building the mathematical description language, so as to realize the reflection of practical problems in a real way. For this reason, the following assumptions are carried out:

Assumption 1: The decision-making behavior of each procedure in the coal industry chain complies with the "economic and rational" assumption. Deep consideration has been carried out to its decision-making process, and the decision-making selection authentically reflected the practical benefits. This assumption is set for eliminating data deviation produced from some radical selection, and eliminating mutation of data set.

Assumption 2: Each procedure of the coal industry chain is in the same environment, and the environmental factor produces the same influence on different decision-making bodies in the same turn.

This assumption is designed for avoiding the inestimable deviation of decision-making behaviors generated from sudden change of the environment.

Individual decision-making model of coal industry chain. As for the operating individuals in the industry chain, there is:

$$MaxZ_n = \sum f(B) - \sum f(C)$$

s.t.

$$\begin{cases} B, C \in N \\ f(B) \geq 0, f(C) \geq 0 \end{cases}$$

That is, as for the n^{th} industry chain, the maximum difference between the total revenue and the total cost is the goal to be pursued.

It can be obtained from the analysis of the function of the above equations,

$$f(B) = \overline{B} \cdot Q$$

$$f(C) = \overline{C} \cdot Q + C_Q + f(C_E)$$

i.e., the revenue of the industry chain and the average product benefits are directly related to the output; while the costs of the industry chain can be divided into three parts, which respectively are variable cost which is directly proportional with the output, fixed cost and upstream transferred cost. In this way, the individual decision-making model of the industry chain can be transferred into:

$$MaxZ_n = Q\sum(\overline{B} - \overline{C}) - C_Q - f(C_E)$$

Network path model of coal industry chain. As for the whole industry chain, the interrelation of different operating individuals forms the operating network, which enables the industry chain to form product cluster in the market to obtain different additional benefits. Considering the network properties of the industry chain, its value transfer and the increment process are accompanying the extending of the value chain, which reflects the chain path extending in the network, therefore, it can be discussed via transferring it into the network model.

Network model is built for the industry chain, and different modes and link names are endowed, which is shown as Figure 1. This network is composed of some nodes of different levels of O, A, B, C, D and their connecting chain path.

The figure is analyzed, combined with the production features of the coal industry chain, and the following results can be obtained:

A. Due to the irreversibility of production and processing, the connection from the upper level nodes to the lower level nodes is smooth; conversely, they cannot be connected.

B. Due to the overlying existence effect of the industry chain and value chain in the industry chain, the one-way arcs in the diagram possess the arc lengths which can be calculated, which shows the cost paid from the upper level procedure to the lower level procedure in the economic significance. Considering the less social labor change of the industry chain in certain period, in order to be convenient for discussion, large change cost can be adopted for the arc length.

C. Each point in the diagram represents different operating individual: who seek profit tendency in decision making, i.e.: economic rationality, therefore, in the environment with different variable costs, more or less path distributary will occur to the network flow.

Decision-making model of coal industry chain. Based on the analysis above, the production and operating behavior of the coal industry chain falls into two parts: individual operating decision-making process and network routing process. In order to integrate them into a system for systematic discussion, confluence analysis should be carried for the two parts.

It can be seen from the analysis of the network diagram of the industry chain that the directed arc parameters in the structure diagram of the industry chain can independently and visually reflect the relation between upstream and downstream individuals.

Therefore, the individuals of the industry chain and the path models can be transferred. The consequences generated from the decision-making behavior of the individual operating in the industry chain is $f(Z_n)$, and those consequences are considered to directly act on the downstream individuals,

and the influence generated from this action possesses uniqueness and the reversible feature. Therefore, the decision-making consequence $f(Z_n)$ can be taken as the path parameter to be combined into the path of the downstream.

The network structure diagram of the industry chain can be transferred as Figure 2.

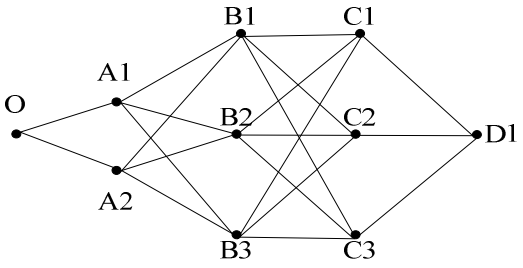

Figure 1. Industry chain network diagram

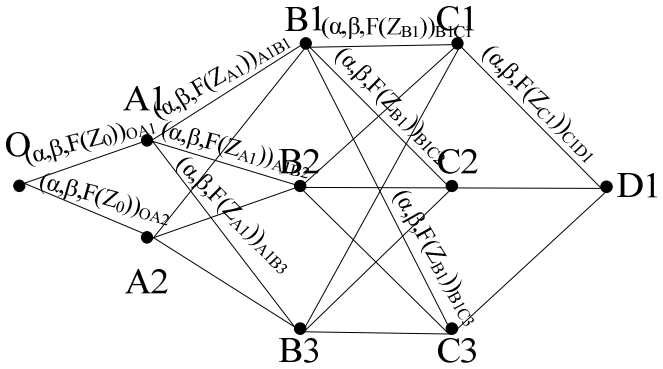

Figure 2. Diagram of industry chain network structure transfer

For the convenience of drawing, only part of the parameter change conditions of industry chain connection is indicated in Figure 2.

As the graphical representation, the individual operating decision function $f(Z_n)$ of the industry chain is taken as a sub-parameter of the directed arc, which is paralleled to the other parameters α and β. While the points in the industry chain network are deemed as smooth knuckles with limitless capacity, i.e.: the directed arcs change direction at the points, which are connected via the points, they are not limited by these points. Being transferred, the parameters of the points in the network diagram are transformed into the arc parameters, which makes it possible to build the model for the whole network structure of the industry chain.

α and β are taken as the cost parameters for influencing the delivery of the industry chain, and C_{ind} as the overall cost of the industry chain, then, the overall decision-making model of the industry chain is:

$$MinC_{ind} = \sum_{i=1}^{n}\sum_{j=1}^{m}(f(\alpha)_{ij} + f(\beta)_{ij} + f(Z)_{ij})$$

Decision-making model of the development of multi-individual coal industry chain. Based on the models with various levels derived from the above deduction, it can be seen that the decision-making model of the development of multi-individual coal industry chain is a group of multi-level programming models, among which: the upper level model reflects the overall benefit demand of the industry chain; the middle level model reflects the benefit demand of each operating individual of the industry chain; while the bottom level model reflects the transfer willingness of the individual cost increment with different levels. The specific mathematic expression equations are as follows:

(M):

$$\begin{cases} \text{(U):} \\ MinC_{ind} = \sum_{i=1}^{n}\sum_{j=1}^{m}(f(\alpha)_{ij} + f(\beta)_{ij} + f(Z)_{ij}) \\ \text{(L1):} \\ MaxZ_n = Q\sum(\overline{B} - \overline{C}) - C_Q - f(C_E) \\ \text{(L2):} \\ f(C_E) = f(R_n, I) \end{cases}$$

Wherein: α and β are the cost parameters for influencing the transfer of the industry chain; C_{ind} is the overall cost of the industry chain; Z is the individual benefit of the industry chain; $\overline{B}$、$\overline{C}$ are the

average benefit and average cost of the individual product of the industry chain; C_Q is the fixed cost; C_E is the upstream delivery cost of the industry chain; R_n is the cost conditions for delivering from different levels of the industry chain to the downstream; and I is the acceptance level of the final consumers.

Model solving algorithm

The solving process of the existing multi-level programming model generally is calculated via transferring it to be the repeatedly nested bi-level programming model[57]. It can be seen from the analysis of the built model that the upper level programming of the model limits the middle level and the lower level, and the middle level also limits the lower level. The upper level programming of the model is connected with the middle level via the variable Z, while the middle level programming and the lower level programming are connected via the variable C_E. Therefore, this model can be transferred to be several bi-level programming problems for solving. The specific model is as follows:

(M1):

(U):

$$MinC_{ind} = \sum_{i=1}^{n}\sum_{j=1}^{m}(f(\alpha)_{ij} + f(\beta)_{ij} + f(Z)_{ij})$$

(L):

$$MaxZ_n = Q\sum(\overline{B} - \overline{C}) - C_Q - f(C_E)$$

(M2):

(U):

$$MinC_{ind} = \sum_{i=1}^{n}\sum_{j=1}^{m}(f(\alpha)_{ij} + f(\beta)_{ij} + f(Z)_{ij})$$

(L):

$$f(C_E) = f(R_n, I)$$

(M3):

(U):

$$MaxZ_n = Q\sum(\overline{B} - \overline{C}) - C_Q - f(C_E)$$

(L):

$$f(C_E) = f(R_n, I)$$

Large difficulties generally exist for solving the bi-level programming problems. On one hand, even the very simple bi-level programming has NP-hard problems, which generally does not have polynomial solving algorithm; another important reason that the lower level programming of this kind of bi-level programming model is essentially a nonlinear constrained problem, therefore, this kind of problem is non-convex programming problem. The locally optimal solution exists, but the globally optimal solution can hardly be found. Please refer to Table 1 for the general solutions of the bi-level programming problems:

Table 1. Table of general solutions of the bi-level programming problems

S.N.	1	2	3	4	5
Method	Simulated annealing algorithm	Tabu search algorithm	Trust region algorithm	Descent algorithm	Genetic algorithm
S.N.	6	7	8	9	
Method	Neural network algorithm	Penalty function algorithm	Great quantity algorithm	Chaos optimization algorithm	

Conclusions

In conclusion, each procedure in the network structure industry chain is deemed to be independent individual, and its choice behavior is included into the overall model for investigation, which can effectively reflect the connection between the overall operation of the industry chain and the individual production.

Keywords: graphic design courses, practice teaching, teaching system

Abstract. Nowadays, the computer graphics technology is widely used in the area of design. The author puts forward the enterprise oriented computer graphic design courses construction of practice teaching system, which is for improving the employment rate of the computer students and making the students can directly blend in the enterprise after graduation. This system includes four big modules. They are the construction of teaching staff, the construction of practical condition and cooperation with enterprise, practice teaching system, teaching quality supervision and feedback system[1]. Each module is decomposed into several small modules.

Introduction

Computers are used in all walks of life, in the rapid development of computer technology today. Computer graphics technology is increasingly mature and development. Computer is widely used in the field of design, so it is to form the computer aided design —CAD. Designers use computer design software such as Photoshop, CorelDRAW etc. to express customer's design thinking, and we can see that the computer is the designers' "hand" and "eye" etc. Nowadays computer graphic design industry is vigorous development in the countries all over the world, especially the country is like Japan. Nowadays, the value which is generated by computer graphic design industry is a significant role in Japan's gross domestic product (GDP). In the world, many countries use relevant preferential policies to promote the development of the computer graphic design industry. Such as in South Korea, the government has set up a special fund to support its development. Comparing with other countries, the development of computer graphic design in our country has a long way to go. In our country, many big cities such as Beijing, Shanghai etc. are very lack of designers. So the author that is based on several years teaching experience proposes the enterprise oriented computer graphic design courses construction of practice teaching system. Through the application of this system in practical teaching situation, it can relieve the lack of designers in surrounding environment and can reduce the investment of the enterprise for the staff and can reassure the parents of students and can make the students find a satisfactory job and can improve our employment and so on.

This system includes four parts: teaching staff, the construction of practical condition and cooperation with enterprise, practice teaching system, teaching quality supervision and feedback system.

The construction of teaching staff

A strong teaching staff is the basic guarantee for completing the teaching process. A strong teaching staff does not mean that the teachers' number is huge; it is double type teacher in theoretical teaching and practical teaching for computer professional graphic design classes. Especially the teachers' practical teaching ability is very important in graphic design courses. In order to develop teachers' practical teaching ability, we can do it from the following aspects:

First, we can organize teachers to participate the enterprise training. By taking part in the enterprise training, that can raise the teachers' practical ability, can cultivate double type teachers, can make teachers zero contact with enterprise and can know what's talent that the enterprise is needed.

Second, we can organize students to take part in skills competition and skills tests. The teachers' practical teaching ability will be improved soon in the process of tutoring for students in skills competition and skills tests.

Third, teachers can improve practical teaching ability through learning himself. As an old saying goes, "it's never too old to learn". It's very necessary to guide the teachers to learn in their spare time. Making all teachers realize that only learning new knowledge constantly won't be eliminated by the society.

The construction of practical condition and cooperation with enterprise

Complete experiment equipment is the basic guarantee for teaching process. For computer graphic courses, complete experiment equipment only need several computers which are installed teaching software. Special instructions, installing teaching control software is very important in addition to install the necessary teaching software in a computer. Through the teaching control software, teachers can broadcast teaching, receive and send a student's work, monitor the student machine, etc. Such auxiliary teaching software is very helpful for practical lesson. Constructing university-enterprise cooperation can prompt the student to zero distance contact with the enterprise, and can reduce the impact for graduate students from training institutions. It's very useful to adopt the training institutions experience in teaching. The teaching methods and teaching means which our college is used should be merged with training institutions, and we should apply flexible. Ultimately it can make the students suit community and market.

Practice teaching system[2]

Course objective. Course objective is the direction of teaching, it is teaching purposes. If it is without direction and purposes in teaching process it can not be called a qualified teaching. We should clear the course objective before teaching, and it should be different for different levels of students. It's not the same course objective for undergraduate students and college students ,For the same course 《Photoshop》. If we want to clear the course objective, we should understand it from three dimensions. The three dimensions are knowledge and skills, processes and methods, emotional attitudes and values. Knowledge and skills are the most basic requirements, they are the most basic knowledge and the most basic skills in the course. For these, the vast majority of teachers can complete. For example, the course《Photoshop》is to teach students how to matting and how to apply filters and other basic skills. Its purpose is to enable students to learn the basic skills of this course. The process and method is to allow students to explore knowledge. It let students themselves identify problems, analyze problems, solve problems. Through this can cultivate the students' innovative spirit and practical ability. For computer graphic design curriculum, teachers can allow students to do curriculum design to achieve this goal. The third dimension is to develop students' emotions, attitudes and values. It is to allow students to have a correct outlook on life, values and world views, so students can have a correct learning attitude, etc. As teachers we should not only teach students knowledge, but also answer students' puzzled. The author believes that "teaching" is to teach basic knowledge, basic skills for course. "Answering puzzle" is to answer all confusion (including outside of the course) for students. Through "answering puzzle" can guide students to the right direction about outlook on life, values and world views. For computer graphic design courses, in this goal, teachers can find some healthy and beautiful life works to guide students' correct emotion, attitude and values.

Course content. If we want to arrange course content, we must first to choose good teaching material. The selection of teaching materials is very important for teaching. For computer graphic design courses, the teaching materials include theory and practice.

Theory is the summary and method of practice, and practice is the embodiment of the theory. They are very important, and both them can't be short of. In order to unify theory and practice, it is feasible to choose a few books as reference. For example the graphic course 《CorelDRAW》, the

author chose two textbook as reference. One course is《CorelDRAW X4 Chinese standard tutorial》of Tsinghua university press, the other course is 《CorelDRAW X3 Computer instruction and practice》of Posts and Telecom Press. 《CorelDRAW X4 Chinese standard tutorial》 is much theoretical content and knowledge system but less instance; 《CorelDRAW X3 Computer instruction and practice》is Based on examples, but knowledge is a bit messy. In the process of teaching, combining with two books will make the teaching process very systemic, and will make students both learn theory and practice at the same time. Of course, for Course content we should omit or add content according to Course objective, should not accept the whole book content.

Curriculum implementation. Curriculum implementation is to implement Course objective and course content. Through curriculum implementation, we can realize course content and achieve course objective. The curriculum implementation must be achieved through teaching activities. In order to implemented better for graphic design courses，teachers must pay attention to the selection of teaching mode, teaching methods and teaching methods. For computer graphic design courses, the author used "issue – found" teaching mode. For example in the "CorelDraw X4" course the author gives the students the work first, and then allows students to check textbooks and to try to do it himself. The last the author explains it. Through practice, the author found that this teaching model is very suitable for teaching practical courses. Teaching method is also very important in the teaching process. The author generally uses the lecture method, practice method, experiment method, practice operating method. Experiment method is particularly important. Traditional teaching methods (a book, a piece of chalk and a blackboard, etc.) can not meet the teaching of computer graphic design courses. In such teaching, the author uses both computers and multimedia.

Course assessment. Course examination includes unit skills, integrated design, vocational skills certification, vocational skills competition four parts, and it isn't a paper to give students the score of a semester or even an academic year. First, unit skills is the usually score, is to check the students' knowledge points of each chapter. Through this, teachers can understand students' understanding of the knowledge points. Then it is integrated design. Grasping every knowledge good isn't necessarily to achieve better results in the integrated design. Because in this design, it is not only check students' knowledge, it is more important to check students' the ability of innovate and the teamwork skills. Finally, vocational skills certification and vocational skills contest can add scores for participating students. By adding scores can encourage students to participate in vocational skills test or vocational skills competition and it can culture student interests.

Teaching quality supervision and feedback system

In order to protect the quality of teaching, the system includes teaching quality supervision and feedback system modules. This module contains four sub-modules: evaluation system, peer assessment system, real-time evaluation mechanisms[3].

Evaluation system. Evaluation System has two parts: Process evaluation and outcome evaluation. In the teaching process，in order to get a good teaching results, you must strictly control the teaching process. So both teaching process and teaching results are important, they need to grasp strictly. Process evaluation has two main objectives: and the quality of student learning. Teaching quality is mainly through college expert evaluation and student evaluation. The quality of student learning is through the evaluation of the employer, of course, also includes the evaluating of the students' parents.

Peer assessment system. Peer assessment system is mainly through listening to each other, learning together for the teachers that teach the same course. For the same course, every teacher has different method, for students which one is the most willing to accept? Through listening to each other, teachers can achieve the purpose of studying together. Thus peer assessment system is a tool for mutual learning and mutual progress for teachers.

Real-time evaluation mechanism. Real-time evaluation mechanism refers experts, parents, employers, peer teachers, students through network or letters to evaluate students learning and to evaluate teachers teaching at any time and any place. The Advantage of real-time evaluation

mechanism for teachers is to know his shortcomings at once, and for students is to receive feedback immediately.

Conclusion

Practice has proved that the implementation of the teaching system is very useful, it can regulate our computer graphic design course of practical teaching, it can enhance teachers' practical teaching ability, and it can improve students' practical ability, innovation ability, etc. Of course, the teaching system is not set in stone, it need to adjust according to actual teaching situation.

Keywords: Cash subadditivity, Risk measures, Product space, Quasiconvexity

Abstract. In this paper, quasiconvex cash subadditivity risk measures for portflios is studied. We propose the concept of quasiconvex cash subadditivity risk measures for portflios and provide a dual representation.Which is more flexible than the one introduced by Cerreia-Vioglio and Maccheroni and Marinacci(2011).

Introduction

Risk measure is one of the most important facets of risk management as capital requirement and principles of premium calculation for the regulator and supervisor. Artzner et al. (1999) firstly introduced the concept of coherent risk measure, by proposing four basic properties to be satisfied by every sound financial risk measure. Föllmer and Schied (2002b) and, independently, Frittelli and Rosazza Gianin (2002)introduced the broader class, named convex risk measure. However, the cash additive axiom has been criticized from an economic viewpoint.Cash additivity fails as soon as there is any form of uncertainty about interest rates.For this reason EL Karoui and Ravanelli (2009) suggest to replace cash additivity with cash subadditivity. But in the situation, the equivalence between convexity and diversification principle no longer holds, in fact,it is implied by quasiconvexity, Cerreia-Vioglio and Maccheroni and Marinacci (2011) proposed quasiconvex risk measure.

Recently,multidimensional risk measures for portfolio vectors have been studied. The multivariate analogue of the Value-at-Risk discussed by Embrechts and Puccetti (2006) is based on set-valued quantiles of the multivariate cumulative distribution function.Jouini et al.(2004) and Kulikov (2008) defined multidimensional risk measures as set-valued functional,and they proved the corresponding representation results. For set-valued measures of risk, see also Cascos and Molchanov (2007), Hamel and Heyde (2010) and Hamel (2006). Burtert and Ruschendorf (2006) defined multidimensional risk measure and proved representation results for convex and coherent risk measures for portfolio vectors.

In the present paper,we will propose a framework of multidimensional quasicovex cash subadditivity risk measures.We will define quasicovex cash subadditivity the multidimensional risk measure and provide the representation results.

Preliminaries

Notations. Let $L^{\infty}(\Omega,\mathcal{F},P)$ be the space of bounded random variables.Its topological dual is denoted by $\mathcal{M}_{1,f}(\mathcal{F})$ and coincide with the set of finitely additive probabilities that are absolutely continuous with respect to P , $\mathcal{M}_1(\mathcal{F})$ is the subset of $\mathcal{M}_{1,f}(\mathcal{F})$ consisting of all its countably additive elements.For this reason,given $X \in L^{\infty}(\Omega,\mathcal{F},P)$ and $\mu \in \mathcal{M}_1(\mathcal{F})$,we indifferently write: $\mu(X)$, $E_{\mu}(X)$ .The specification of the probability space $(\Omega,\mathcal{F},P)$ is often omitted and we just write L^{∞} , $\mathcal{M}_{1,f}$ .From now on, let $N \geq 1$ be a fixed positive integer.For $1 \leq i \leq N$,we denoted by g_i the

space $L^{\infty}(\Omega_i, \mathcal{F}_i, P_i)$ .Let g^N be the product space $g_1 \times \ldots \times g_N$, $I = (1, \cdots, 1)$, $aM = (aX_1, \cdots, aX_N)$, $a \in R$,if $a = (a_1, \cdots, a_N) \in R^N$,the $aM = (a_1 X_1, \cdots, a_N X_N)$ .For $M_1 = (X_1, \cdots, X_N) \in g^N$, $M_2 = (Y_1, \cdots, Y_N) \in g^N$, $M_1 \le M_2$ means $X_1 \le Y_1, \cdots, X_N \le Y_N$, $M_1 + M_2$ stands for $(X_1 + Y_1, \cdots, X_N + Y_N)$, $M = (X_1, \cdots, X_N) \in g^N$,define $\|M\| = \|X_1\| + \cdots + \|X_N\|$, $I = (1, \cdots, 1)$,where $\|X_i\| = \sup_{\omega \in \Omega} |X_i(\omega)|$,

then $(g^N, \|\cdot\|)$ is a Banach space. We can interpret $(g^N, \|\cdot\|)$ in two distinct but related ways:

(1) For $M = (X_1, \cdots, X_N) \in g^N$, M can be understood as a portfolio held by a firm with its subportfolios $X_1, \cdots, X_N$. X_k can be interpreted as the payoff an asset of type $k \in \{1, \cdots, N\}$. Under this interpretation, g^N stands for all the portfolios held by the firm.

(2) We can represent a firm by an element $M = (X_1, \cdots, X_N) \in g^N$, $1 \le i \le N$ where X_k is referred to the k^{th} portfolio of the firm M , and can be interpreted as the payoff a business of type $k \in \{1, \cdots, N\}$ .In this case, g^N stands for all the firms. This interpretation can be adopted in the capital allocations.

Quasiconvex cash subadditivity risk measure. EL Karoui and Ravanelli (2009) replaced cash additivity with cash subadditivity, named cash subadditivity risk measure.

Definition 2.1 A cash subadditivity risk measure is a function $\rho : L^{\infty} \to R$ monotonicity,convex and satisfying the following cash subadditivity.

$$\rho(X + m) \ge \rho(X) - m, m \in R^+$$

Remak: The meaning of this condition is" when m dollars are injected into a future position the present capital requirement is reduced by less than m dollars ".This is a much more compelling assumption than cash additivity since it just relies on the fact that an additional reserve of m dollars surely cover the additional loss of the same amount.

Cerreia-Vioglio and Maccheroni and Marinacci(2011) relaxed the convexity into quasiconvexity and draw quasiconvex cash suadditivity risk measure.

Definition 2.2 If a map $\rho : L^{\infty} \to R$ satisfies with monotonicity,cash subadditivity and the following quasiconvex property

$$\rho(\lambda X + \lambda Y) \le \max(\rho(X), \rho(Y)) \quad X, Y \in L^{\infty}, \lambda \in (0,1)$$

Then ρ called quasiconvex cash subadditivity risk measure.

Theorem2.1(Cerreia-Vioglio and Maccheroni and Marinacc) A function $\rho : L^{\infty} \to R$ is a quasiconvex cash subadditivity risk measure if and only if there exists $F \in F_1(R \times \mathcal{M}_{1,f})$ such that

$$\rho(X) = \max_{\mu \in \mathcal{M}_{1,f}} F(E_{\mu}(-X), \mu) \text{ ,for any } X \in L^{\infty}, \mu \in \mathcal{M}_{1,f} . \quad (1)$$

The function $F \in F_1(R \times \mathcal{M}_{1,f})$ for which (1) holds is unique and

satisfies $F(t, \mu) = \inf\{\rho(X), E_{\mu}(-X) = t\}$,for any $(t, \mu) \in (R \times \mathcal{M}_{1,f})$

Main results

In this section,we shall define quasiconvex cash subadditivity risk measure for portfolios, and provide the corresponding representation result.

Definition 3.1 A risk measure $\rho : g^N \to R$ is called a quasiconvex cash subadditivity risk measure for portfolios,if it satisfies the following three axioms:

(a)Monotonicity: $M_1 \le M_2$ implies $\rho(M_1) \ge \rho(M_2)$ for any $M_1, M_2 \in g^N$.

(b)Cash subadditivity: $\rho(M + (a_1 + \cdots + a_N)) \ge \rho(M) - (a_1 + \cdots + a_N)$ for any $M \in g^N, a_i \in R^+$.

(c)Quasiconvexity: $\rho(\lambda M_1 + (1 - \lambda) M_2) \le \max(\rho(M_1), \rho(M_2))$ for any $\lambda \in (0,1)$ $M_1, M_2 \in g^N$.

Remark Let $\rho : g^N \to R$ be a quasiconvex cash subadditivity risk measure for portfolio vectors. ρ is normalized,when $\rho(0)=0$,Define $\rho_i : g_i \to R$ as $\rho_i(X_i) := \rho(Me_i)$ .Then ρ_i is a quasiconvex cash subadditivity risk measure for portfolios on g_i .Conversely ρ_i is quasiconvex cash subadditivity risk measure for portfolios on g_i .Then define $\rho(M)=\rho_1(X_1)+\cdots+\rho(X_N)$ is also a quasiconvex cash subadditivity risk measure for portfolios. Let $\mu=(\mu_1,\cdots,\mu_N)\in \mathcal{M}_{1,f}^N$, $\mathcal{M}_{1,f}^N := \mathcal{M}_{1,f}(g_1)\times\cdots\times\mathcal{M}_{1,f}(g_N)$, $E_\mu(M)=E_{\mu_1}(X_1)+\cdots E_{\mu_N}(X_N)$ for any $M\in g^N$.

Proposition 3.1 let ρ_i be a quasiconvex cash subadditivity risk measure if and only if ρ_i is quasiconvexity and Lipschitz continuous with constant 1.

Proof: if ρ_i is Lipschitz continuous with constant 1,then $\rho_i(X_i)\le\rho_i(X_i+a_i)+\|X_i-(X_i+a_i)\|$ for any $X_i\in g_i$, $a_i\in R^+$, that is, $\rho_i(X_i+a_i)\ge\rho_i(X_i)-a_i$ .Conversely, $X_1,X_2\in g_i, X_1-X_2\le\|X_1-X_2\|$,the $X_1-\|X_1-X_2\|\le X_2$,monotonicity and cash subadditivity imply $\rho_i(X_2)\le\rho_i(X_1-\|X_1-X_2\|)\le\rho_i(X_1)+\|X_1-X_2\|$,as wanted.

Theorem 3.1. Any quasiconvex cash subadditivity risk measure for portfolios ρ on g^N is of the form $\rho(M)=\max\limits_{(\mu_1\cdots\mu_N)\in\mathcal{M}_{1,f}(g_1)\times\cdots\mathcal{M}_{1,f}(g_N)} F(E_{\mu_1}(X_1)+\cdots E_{\mu_N}(X_N),(\mu_1\cdots\mu_N))$ for any $M\in g^N$ .The function is unique and satisfies $F(t,\mu)=\inf\{\rho(M):E_\mu(-M)=t\}$ for any $(tI,\mu)\in R^N\times\mathcal{M}_{1,f}^N$.

Proof: It only remains to show that ρ is qusiconvex cash subadditivity risk measure for portfolios if and only of F is Lipschitz continuous with constant 1 in the first component.

suppose ρ is cash subadditivity,then for $(tI,\mu)\in R^N\times\mathcal{M}_{1,f}^N$ and $m\in R^+$

$$F(t+m,\mu)=\inf\{\rho(M):E_\mu(-M)=t+m\}=\inf\{\rho(M):E_\mu(-M-mI)=t\}$$
$$=\inf\{\rho(H-mI):E_\mu(-H)=t\}\le\inf\{\rho(H)+m:E_\mu(-H)=t\}=F(t,\mu)+m$$

Therefore,monotonicity of F we can get the following inequality

$F(t',\mu)\le F(t+|t-t'|,\mu)\le F(t,\mu)+|t-t'|$, $t,t'\in R$, $\mu\in\mathcal{M}_{1,f}^N$

Conversely,if F is quasiconvex and Lipschitz continuous with constant 1 in the first component,then,for all $(tI,\mu)\in R^N\times\mathcal{M}_{1,f}^N$ and $m\in R^+$,

$$F(t+m,\mu)\le F(t,\mu)-|t-(t+m)|=F(t,\mu)+m$$

Moreover,for all $M\in g^N$,There is $\mu'\in\mathcal{M}_{1,f}^N$,such that

$$\rho(M-mI)=F(E_{\mu'}(-(M-m)),\mu')\text{ .Therefore}$$
$$\rho(M-mI)=F(E_{\mu'}(-(M-mI)),\mu')\le F(E_{\mu'}(-M),\mu')+m$$
$$\le\max_{\mu\in\mathcal{M}_{1,f}^N}F(E_\mu(-M),\mu)+m=\rho(M)+m$$

Proposition. Let $\rho : g^N\to R$ can be an upper semicontinuous and quasiconvex risk measure for portfolios.Then ρ is positively homogeneous if and only if $F(\cdot,\mu)$ is positively homogeneous for any $\mu\in\mathcal{M}_{1,f}^N$.

Proof:Let $t\in R$, $\lambda\in(0,\infty)$ and $\mu=(\mu_1\cdots\mu_N)\in\mathcal{M}_{1,f}^N$, $M\in g^N$ then

$$F(\lambda t,\mu)=\inf\{\rho(M):E_{\mu_1}(-X_1)+\cdots+E_{\mu_N}(-X_N)=\lambda t\}=\inf\{\rho(M):E_{\mu_1}(\frac{-X_1}{\lambda})+\cdots+E_{\mu_N}(\frac{-X_N}{\lambda})=t\}$$
$$=\inf\{\rho(\lambda H):E_{\mu_1}(-H_1)+\cdots+E_{\mu_N}(-H_N)=t\}=\inf\{\lambda\rho(H):E_{\mu_1}(-H_1)+\cdots+E_{\mu_N}(-H_N)=t\}$$
$$=\lambda\inf\{\rho(H):E_\mu(-H)=t\}=\lambda F(t,\mu)\text{ .}$$

Conversely,assume that $F(t,\mu)$ is positive homogeneous for all $\mu=(\mu_1\cdots\mu_N)\in\mathcal{M}_{1,f}^N$ and let $M\in g^N$ and $\lambda\in(0,\infty)$ .Then

$$\rho(\lambda M)=\max_{\mu\in\mathcal{M}_{1,f}^{N}} F(E_{\mu_1}(-\lambda X_1)+\cdots+E_{\mu_N}(-\lambda X_N),(\mu_1\cdots\mu_N))=\lambda\max_{\mu\in\mathcal{M}_{1,f}^{N}} F(E_{\mu_1}(-X_1)+\cdots+E_{\mu_N}(-X_N),(\mu_1\cdots\mu_N))$$
$$=\lambda\max_{\mu\in\mathcal{M}_{1,f}^{N}} F(E_{\mu}(-M),\mu)=\lambda\rho(M).$$

Conclutions

We have introduced the concept for quasiconvex cash subadditivity risk measure for portfolios and provided its representation theorem,which is more flexible than the one introduced by Cerreia-Vioglio and Maccheroni and Marinacci(2011).

Keywords: Community service; Urban community; Community net store; Characteristic; Purchase predisposition

Abstract. This article is primarily for the research and analysis of demand for commercial service of urban community. First of all, it suggests the urgency and importance by redefining community's connotation and function from the views of the development of society. Then through questionnaires we visited community residents in 18 districts of Tianjin, and finally sum up the essential characteristics and purchase predisposition of consumer of community commercial service.

Introduction

Currently, most urban living environment is mostly developing as community, today electronization is becoming more and more often stressed, community should not only provide the safe living environment, but be functional for business use as well. The electronization of community provides communication channels among residents, it control and ensure the digitization and internetization in the community and community availability of community information.[1] Although community residents can do shopping at the nearby department stores, the purchase costs will be relatively raised. If we can integrate their demand for commodities and develop the chain-store model, we'll be able to do large bulk purchases so as to provide cheaper goods and more convenient service for community residents. Thus it can be seen that the rapid development of modern community, perfect pattern of community management and community electronization are the foundation of modern community. To community service provider and other outside businesses, community means commercial opportunity. And what they call community commerce is defined as a business different from regional business center, huge shopping centers and featured pedestrian shopping streets, it is strongly regional and mainly for residents in region.[2] So we must research the purchase characteristics of community residents, their purchase tend to diversification, topicalization and individuation. And the demand is transforming from subsistence to a comfortable life. What the community service system we're establishing need to do is to draw this "community commercial map", building the information bridges between commercial tenant and resident, helping residents find the goods or service they need rapidly. [3] This passage assessed Tianjin, and analyzes characteristics and purchase predisposition of consumer of urban community commercial service through sending questionnaires to residents in 18 districts.

Empirical research of community commercial service in Tianjin

Questionnaire design and sample selection. The purpose of this research is as following: before building the logistics system, we should know exactly what residents want to community. So we can set up a community service system that meets the residents' demand. This investigation is for studying residents' demand to community commerce, especially to community net store, the new business model. [4, 5] The samples of this research are residents of 18 districts in Tianjin. The questionnaire contains four sections: the first part is about the buying situation of community store, there are 8 questions, including their buying reason, types of goods, purchasing frequency, consumption amount, the important factors and pointless factors, products they want to add, etc. The

second part is the research about networking situation, there are 13 questions, including the buying reason, the type of goods, purchasing frequency, consumption amount, payment method, unpleasant experience, what they want to be improved and why they don't choose online shopping, etc. The third part is about how they think about community online supermarket, there are 14 questions, including whether they accept this new way to shop or not, why they like the networking supermarket or why don't, what kind of goods they want to buy, what service they want to be provided, factors they think important as well as that they think pointless and what they think about the development prospect of this new shopping way, etc. The last section is about the respondents' basic information, there are 6 questions, including their district, age, family structure, educational status, profession and monthly income.

Questionnaire recovery and general situation. The questionnaires are mainly distributing to residents from 18 districts including 6 areas, 4 suburbs, 5 counties and Binhai New Area in Tianjin. The qualities is as following: 100 to 6 areas in the city, 150 to Xiqing (where the school is located) and 50 to every other area. Totally 1300 questionnaires have been given out, and the recovery rate is 100%. After screening, we got 544 effective questionnaires which account for 42.62 percent among it.

The 554 effective questionnaires show: First, from the aspect of areal distribution, it is not balanced in 18 districts, Xiqing (24%) and Nankai (17%) rate is much higher, because more questionnaires have been given out there, and respondents are serious about this for their high educational status. Second, from the aspect of age, it is also not balanced because most respondents are from 15 to 55, as well as most questionnaires from the young or the old are not available. Effective questionnaires are mainly from people ages 15 to 35, which account for 85%, for there are much more people of this age are our respondents and their questionnaires are more normative. Third, As the hand of family structure, 64% respondents are unmarried, this is because their ages are mainly from 15 to 35, they care more about fashion, personality and Less quantitative, so it's easier for them to accept new business model. Married people account for 35%, their families are mainly of three people, and their shopping is focus on babies, they pay more attention to the benefits and convenience. Fourth, on the hand of educational status, respondents are from sorts of background. Most are undergraduate students (57%), because more respondents are from them and most of their questionnaires are effective. Sixth, seen from the family incomes, most are between 2000 and 6000 Yuan, which accounts for 60%, the income reflects purchasing-power terms.

Demographic characteristics of the target customers. The research makes the group who do frequent community store shopping and always do online shopping. The so-called frequent community store shopping is consumers who go to community store at least once.

After the analysis of 554 effective questionnaires, 338 people are selected as the target consumers. The demographic characteristics of these 338 people are described as the following Fig.1.

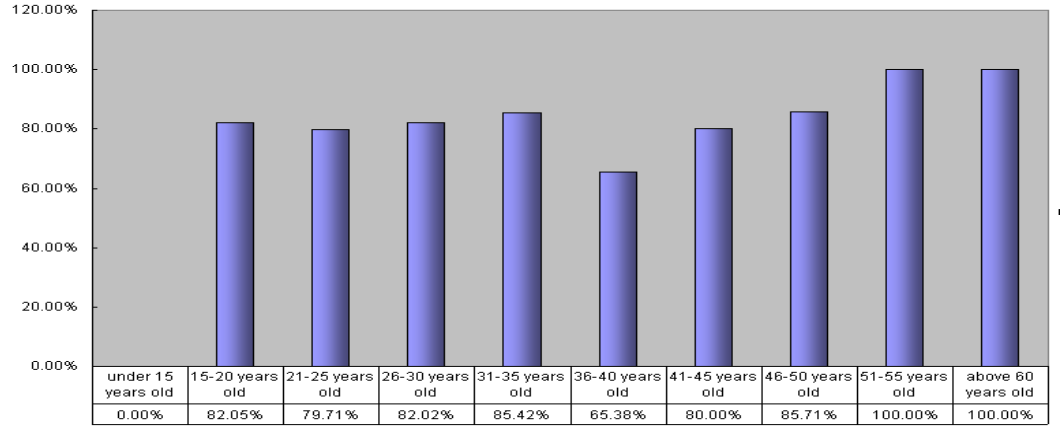

Figure1. The proportion of target of all ages

First, from the geographical point of view, the target consumers concentrated in the more affluent and higher maturity areas, the proportion of target consumers exceeds 50 percent in most areas expect Hebei District, Jinan District, Ninghe Contry, Baodi Contry and Dagang District. And the proportions

of Jinnan District, Ninghe contry, Baodi Contry are lower than 40 percent .This data shows that Tianjin has high potential demand of the community services.

Second, judging from the age structure, the target consumers of all ages account for more than 60 percent, except the group under 15 year-age (for the respondents are too less), and the needs of the elderly of the community services are greater than that of the young.

Third, from the marital status, the proportion of the married and unmarried groups are both more than 80 percent.

Fourth, from the educational background, target customers of the crowd who do not enter high school makes up the lowest proportion, the PhD group accounts for a little more proportion. While the target consumers of university student are the most. The proportion of target customers increases as qualifications increase when educational background from junior high school to university level, while it is the opposite when it comes to the situation from the university to PhD. The data shows that the crowds of university undergraduate are relatively most easy to accept new things, and low degree group might do not accept so much because of the difficulties caused by the application of new things, while the high degree group might do not accept so much because they have more questions and concerns to new things.

Fifth, from the professional vie, the proportion of target customers from financial officers and auditors is the lowest, the proportion of customer service staff is a little higher, the target customers of the independent entrepreneurs accounted for a greater proportion, while the target customers from the rest of the occupational background is more than 75 percent.

Sixth, When it comes to the purchasing power, the target customers of high-income groups exceed 50 percent, thought it declines.

Target customers purchase tendency analysis. This research will analysis the purchasing preference, to provide a basis for the determination of the business scope, product selection, service content choice and service level choice of the new business model.

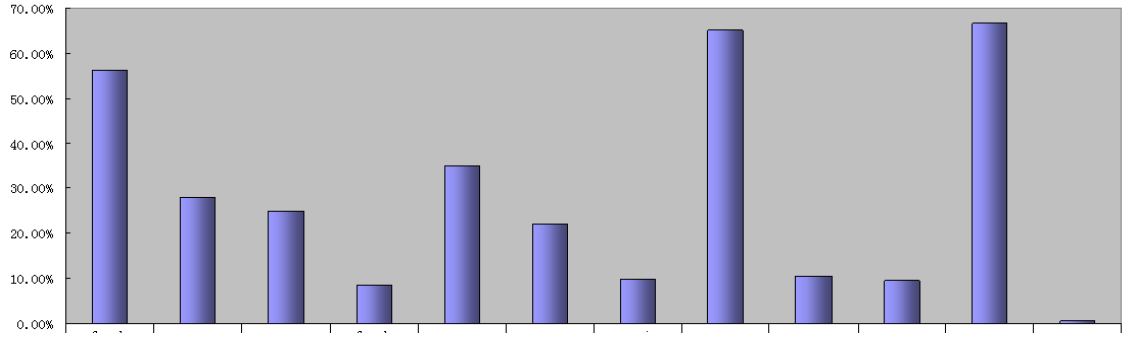

Figure2. The commodity type purchased by the target customers in the community stores

First, from a commodity type of view, On the one hand, community residents major buy daily necessities, snacks , fresh fruits and vegetables, things like milk, rice, meat, eggs and so on are not considered so much, just as shown in Fig.2. At present, the fresh local aquatic products, semi-finished products, breakfast and dinner do not sell that well, which was caused by the lack of providing a wide variety of these goods. While the supply of these goods becomes essential as people working rhythm speeding up, there is potential requirement of these kinds of goods.

One the other hand, the commodity types which the target consumers want to get more mainly are medicine, book, CDs and metal tools. The next is the demand of the cosmetic, maternal and infant supplies, health care products, and cars, just as what was shown in Fig.3. So the amount of these goods can be increased in the community net stores.

Second, we analyzed the point of consumption amount. Above all, we find that the quantity of the target consumers who expend twenty Yuan to fifty Yuan one time accounted for the largest proportion, which reaches 38.76 percent. The quantity who's a single consumption under 20 Yuan or more than 100 Yuan is fewer, which are 11.24 percent and 11.83 percent respectively. This shows that community store commodity whose unit price is higher is not easy to be selected. In the next place, we need to analysis the shopping frequency of the target customers go to community store, which help us

grasp better the spending power of the community store. The data shows that most people go to community store every two or three days, the proportion reaches 51.78 percent, which explain that consumers always solve temporary needs or emergency required in the community store.

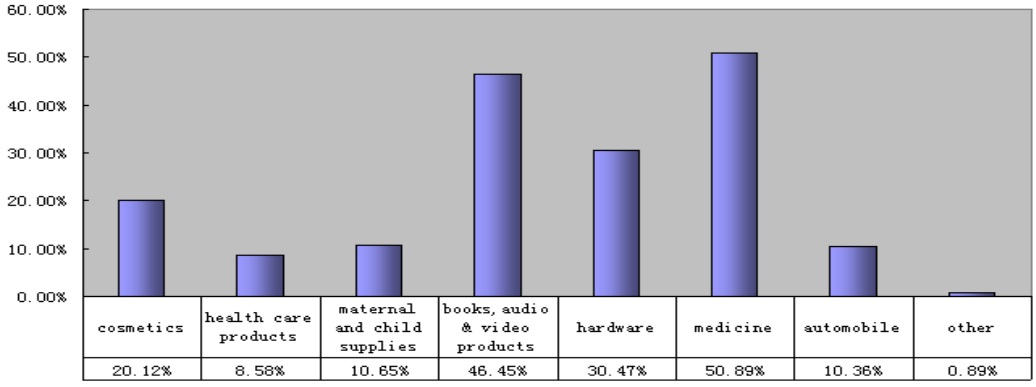

Figure3. The commodity types the target consumers want to increase

Third, by analyzing the demand points, we find that: First of all, the most attractive place of the community net store is its characteristic of shopping convenient, low prices and home delivery. Unlike online shopping, the consumers see the time-saving and home delivery more important when they surf the community net store. In addition, the consumers like the community net store of its temporary emergency, fashion and fun; they can easily get a lot of goods information and shop around. Specific data is shown in Fig.4.

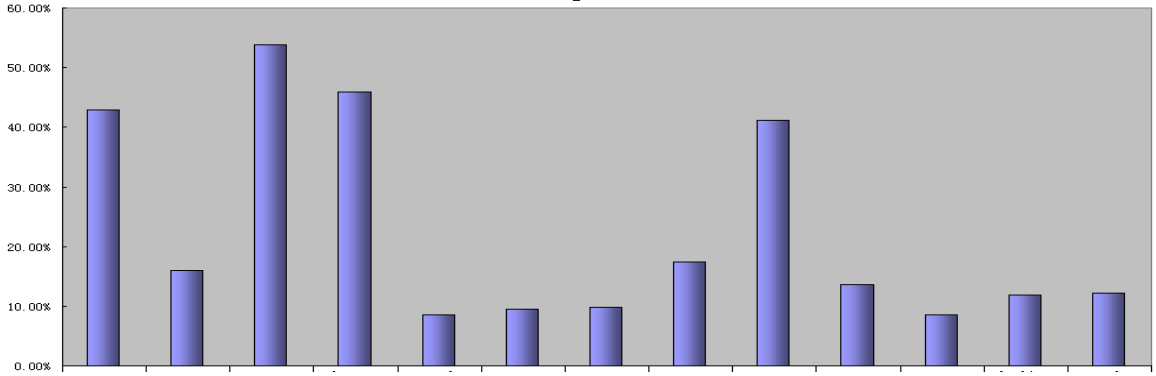

Figure4. The most attractive of the community net store

In the next place, the quality of goods is the most important one, the proportion of people who hold this idea is 81.66 percent. Others think that timeliness, prices and integrity management are also important. Moreover, the full range of products, after-sales service, network security, service attitude, real information and legal protection also matter. Fig.5 shows these messages.

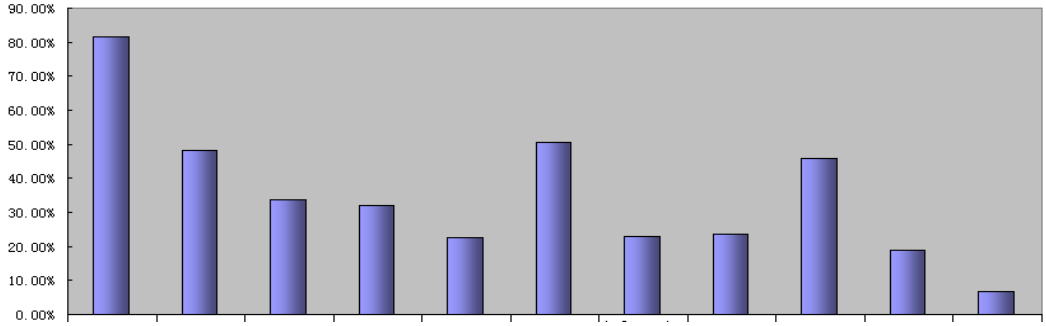

Figure5.Which characteristics of the community net store is important

Furthermore, we should do point analysis for the target consumers, because we have to get not only what he cares most about, but also what does not matters. We should better maximize the limited resources to improve consumer satisfaction for we do not own so endless resources. The majority of people believe shopping atmosphere, after-sales service is not important to the community store. In addition, traffic convenience does not play an important role as supermarket for it mainly addresses the needs of local residents. One the other hand, a lot of people think that personalized service is not

important, because everyone do this shopping mainly for temporary and emergency needs which do not involve too much customization needs.

Conclusions

The paper focuses on Tianjin, make research of residents from 18 districts and counties of community.

On the one hand, we can describe the basic characteristics of the target customers through data analysis. Large potential demand for community services exists in the more affluent and higher maturity areas. The needs of the elderly of the community services are greater than that of the young. The choice of whether to accept a community service does not be affected by the family structure; it only affects the demand point. The proportion of target customers increases as qualifications increase when educational background from junior high school to university level, while it is the opposite when it comes to the situation from the university to PhD. The highest proportion 0f target customers are the Bachelor. The proportion of target customers from financial officers and auditors is the lowest, the proportion of customer service staff is a little higher, the target customers of the independent entrepreneurs accounted for a greater proportion, while the target customers from the rest of the occupational background is more than 75 percent. When it comes to the purchasing power, the target customers of high-income groups exceed 50 percent, thought it declines.

On the other hand, we can draw the purchasing preference of the target customers through data analysis. From a commodity type of view, community residents major buy daily necessities, snacks, fresh fruits and vegetables, things like milk, rice, meat; eggs and so on are not considered so much. The type of goods they want to increase mainly are medicine, book, CDs and metal tools, then the cosmetic, maternal and infant supplies, health care products, and cars. Judging from the amount and proportion of the expense, the quantity of the target consumers who expend twenty Yuan to fifty Yuan one time accounted for the largest proportion, which reaches 38.76 percent. A number of people go shopping every two or three days, the proportion reaches 51.78 percent. When it comes to the demand points, the most attractive pace of community net-supermarket are shopping convenient, low prices and home delivery. In addition, the consumers like the community net store of its temporary emergency, fashion and fun. They also consider the shopping atmosphere, after-sales service and traffic convenience not so important.

Keywords: physical education; evaluation system; AHP

Abstract. In today's competitive educational environment, the quality of physical education is ever more recognized as a fundamental factor in gaining competitive advantage. The evaluation and improvement of the quality of physical education in higher education is an important issue of on-going concern. The aim of this article is to focus on an automated management and evaluation system to efficiently control the administration of physical education. Reported in this article is an evaluation index of the quality of undergraduate education, and an analytic hierarchy process (AHP) model that is both practical and has proven to be successful. The results of the presented case study demonstrate the practicability and effectiveness of this model in physical education quality evaluation.
